useful experiment in the sphere of museums They therefore propose, with the collaboration of the Museums Association, to explore this possibility This broadly conceived experiment opens up wide prospects of benefit to the public through the agency of museums, and we wish it every success

Prof Niels Bohr, of Copenhagen, will deliver the Faraday Lecture of the Chemical Society on May 8, taking as his subject "Chemistry and the Quantum Theory" The lecture will be delivered at the Salters' Hall, St Swithin's Lane, E C 4

The Faraday Medal of the Institution of Electrical Engineers will be presented to Sir Ernest Rutherford at the ordinary meeting of the Institution to be held on Thursday, May 1 The presentation will precede the twenty first Kelvin Lecture, which will be delivered by Mr R H Fowler on "Some Recent Advances in the Electron Theory of Metals"

The following appointments have been made at the Museum of Science and Industry, Chicago Dr Louis Ehrenfeld, of North western University, to be curator of organic and industrial chemistry, Mr Herman R Eberle, of the Michigan College of Mining and Technology, to be assistant curator of mining, Mr M K Hubbard, of the University of Chicago, to be research associate in geology and geophysics

Sir William Bragg, Fullerian professor of chemistry in the Royal Institution and director of the Davy Faraday Research Laboratory, who has been awarded the Franklin Medal for his work on X rays and crystal structure (Nature, Feb 22, p 286), will visit the United States shortly, when he will receive the Medal in the hall of the Franklin Institute, Philadelphia, on May 21 and deliver an address Sir William will also give lectures at Johns Hopkins University, Baltimore, at Columbia University, New York, and at Princeton University

Prof M Siegbahn, of the Physical Institution, Uppsala, referring to the article on the Nobel Foundation in Nature of Mar 29, writes to say that when Dr Nobel was asked to send to the University of Uppsala some biographical details in connexion with the conferment upon him of the honorary degree of doctor of philosophy, he stated that he was a member of the Royal *Institution of London*, and no mention was made of the Royal *Society* The quotation given in Nature was from Nobel's "Life", which was translated from the German work We suggest that though Nobel wrote *Institution* in his note, this was inadvertently understood as *Society* when rendered into German or in the English translation where the word wrongly appears

The following medal awards for 1929 and 1930 have been made by the American Geographical Society *Cullum Geographical Medal* for 1929 Dr Hugh Robert Mill, formerly director of the British Rainfall Organization, Prof Jean Brunhes, professor of human geography at the Collège de France, and author of "La géographie humaine", and related works, Prof Alfred Hettner, professor of geography in the University of Heidelberg, and founder and editor of the *Geographische Zeitschrift*, and Prof Jules de Schokalsky, professor of oceanography in the Leningrad State University, and president of the Russian Geographical Society Awards of the Cullum Geographical Medal, given from time to time to those "who distinguish themselves by geographical discoveries, or in the advancement of geographical science", had not been made since 1925 *Charles P Daly Gold Medal* for 1929 Cav Filippo De Filippi, secretary general of the International Geographical Union, who has done distinguished work in exploration, and Prof Émile Félix Gautier, of the University of Algiers The Charles P Daly Gold Medal is awarded from time to time "for valuable or distinguished geographical services or labours" The last award was made in 1927

Fowl typhoid, an acute infectious disease of fowls, is the subject of a leaflet (No 39) issued by the Ministry of Agriculture and Fisheries The symptoms, diagnosis, and spread of infection are described, and directions are given for eradication and prevention

The *Journal of the Cancer Research Committee of the University of Sydney* for February (vol 1, No 4) contains an article by W B S Bishop on the occurrence and possible importance of the metallic elements in animal and plant tissues A very useful summary of the subject is given, with a list of 143 references to the literature

A second edition of "A Summary of Facts regarding Malaria", by Sir Ronald Ross and Sir Malcolm Watson, has been issued (John Murray, Albemarle Street, W, 6*d*) This pamphlet gives an excellent popular account of malaria, and the parasites and the fever, the mode of infection, and some facts concerning mosquitoes are briefly described The final pages deal with prevention, personal and public, of the disease

The March issue of the *Bulletin of Hygiene* contains a review by Dr J D Rolleston of recent literature on the tobacco problem, including the historical aspects and prevalence of the tobacco habit, experimental work in connexion with nicotine and other constituents of tobacco smoke, the nicotine content of cigars and cigarettes, with special reference to so called 'denicotinised' tobacco products, the relation of tobacco to public health, and the pathological effects of tobacco, especially on the alimentary, cardio vascular, and nervous systems

Applications are invited for the following appointments, on or before the dates mentioned —A geologist in the Geological Survey Office, Department of Industry and Commerce, Irish Free State—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, C 8 (April 30) A full time assistant teacher in the Engineering Department and Junior Technical School of the Harris Institute, Preston—Principal and Secretary, Harris Institute, Preston (May 2) An assistant clinical pathologist at the General Hospital, Birmingham—The House Governor, General Hospital, Birmingham (May 6)

A head of the Department of Mechanical Engineering, an assistant master in botany and chemistry, an assistant master in electrical engineering, and a teacher of workshop practice (electrical and motor engineering) at the Liverpool Central Municipal Technical School—The Director of Education, Education Offices, 14 Sir Thomas Street, Liverpool (May 7) An assistant in electrical engineering at the Rutherford Technical College, Newcastle upon Tyne—The Director of Education, Northumberland Road, Newcastle upon Tyne (May 17) A full time graduate assistant in the Department of Engineering of the Leicester College of Technology—The Registrar, College of Technology, Leicester (May 18) An assistant professor of chemistry in the University of Manitoba—The Secretary to the Board of Governors, University of Manitoba, Winnipeg, Canada (June 1) A professor of physiology at Middlesex Hospital Medical School—The Academic Registrar, University of London, South Kensington, S W 7 (June 12) A development officer and a research manager under the British Non Ferrous Metals Research Association — The Director, British Non-Ferrous Metals Research Association, 71 Temple Row, Birmingham A junior assistant under the Directorate of Explosives Research of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S E 18

Our Astronomical Column.

The Lowell Object —A very remarkable orbit of this object has been computed by the Flagstaff astronomers, and distributed by telegram from Prof Shapley (*I A U Circular*, No 271) They find an ellipse with eccentricity, 0 909, semi major axis, 217 units, perihelion distance, 19 64 units, perihelion passage, 1900 5, longitude of perihelion, 12° 52′, ascending node, 109° 21′, inclination, 17° 21′ mean daily motion, 1 112″, period, 3191 years, present distance from sun, 41 3 units There is no doubt that the present distance and the node and inclination are near the truth, but the eccentricity is stated to be uncertain If the above value is right, the object would have been of the twelfth magnitude when in perihelion, so that there ought to be little difficulty in finding images of it on old plates It is advisable to make search in the first place on fairly recent plates, as the limits of error are much smaller, the following short ephemerides have been prepared from these elements, they are for 0 h

1928		R A	N Decl	1929		R A	N Decl
Jan	1	7h 9m 11s	21° 23	Jan	1	7h 15m 8s	21° 39
,,	17	7 7 40	21 27		17	7 13 40	21 42
Feb	2	7 6 15	21 30	Feb	2	7 12 16	21 46

The uncertainty of these positions is much smaller than that of the elements, and should not exceed a few minutes of arc All the observatories that search for minor planets are likely to have plates of the region Rough ephemerides for earlier years can be formed from the annual differences shown above

Periodic Changes in the Solar Corona — The connexion between the form of the corona and the phase of the sun's general activity in the 11 year period has long been known, with the natural result of a similar (though less marked) relation with the sun's spotted area Dr W J S Lockyer pointed out in 1903 that prominences were related much more closely than spots to the coronal form, and fully confirmed this result by a further research in 1922 in which the material was brought up to date In a recent paper (*Upsala Meddelanden*, No 46) Prof Bergstrand reaches the same conclusion by an analysis of previously published results of Ludendorff, in which the latter gives 'isophotes' (lines of equal luminosity in the corona) for different eclipses Bergstrand gives a correction to these isophotes in the polar regions to allow for the superposition of streamers from equatorial or intermediate latitudes, and deduces a quantity, p, giving the ratio of coronal luminosity in equatorial and polar regions at the same height above the solar surface There is a slight correlation between p and sunspot numbers, but the variations in the former follow much more closely those of prominences in the high latitude zone Prof Bergstrand is led to the "irresistible impression that the strong development of the polar corona towards the epoch of sunspot maximum is related to the simultaneous appearance of prominences in the neighbourhood of the solar poles", thus strongly supporting the work of Lockyer mentioned above

Radial Velocities of 741 Stars —A valuable addition to our knowledge of stellar radial velocities appears in the *Astrophysical Journal*, vol 70, p 207, in which results are given for 741 stars measured at the Mount Wilson Observatory by Messrs Adams, Joy, Sanford, and Strömberg The 60 inch and 100 inch reflectors were used, with one prism spectrographs giving dispersions ranging from 37 A to 76 A per mm in the neighbourhood of $H\gamma$ The majority of the stars are of spectral types F to M, but some (91) of types O, B, and A are also included Their visual magnitudes range from 3 0 to 10 8, most of the fainter stars being dwarfs with large proper motions which show (as might be expected) a considerable proportion of large radial velocities An interesting feature of the results is the almost complete absence of large positive velocities from R A 15h to 2h in the northern hemisphere, thus illustrating the asymmetry of stellar motions previously noted by Stromberg This list brings the number of radial velocities determined by the two large Mount Wilson reflectors up to a total of 1754

Handbook of Cracow Observatory for 1930 —This is the eighth issue of this useful annual handbook, which is edited by Prof Banachiewicz The greater part of it is occupied with ephemerides of variable stars, both long period and eclipsing Then follow tables of obliquity of ecliptic, precession, selenographical co ordinates, and predictions for 1930 of occultations of stars by the moon, for five observatories in Poland It is suggested that the selenographical co ordinates may be used to find the regions of the moon at which occultations occur, and then apply corrections for the altitudes of these regions This is a refinement that will doubtless become general in the future, there is not the same need for it in meridian observations of the moon, as a long arc of the limb is visible, and the eye can make an estimate of the mean position of the limb, which is certainly more accurate than observing an outlying mountain But in all the most accurate observations of occultations the limb is dark, and these irregularities are invisible The headings and explanations of the tables (except those relating to the details of occultations in Poland) are given both in Polish and in flexible Latin, the latter being easy to read

Research Items

Australian Petroglyphs—The discovery of a number of petroglyphs, believed to be new, by Mr B E Hornshaw is recorded in the *Victorian Naturalist* for February Mr Hornshaw has spent some twenty years searching for art relics of the aborigines and has found many examples previously unknown Those which he now describes are situated in Kuring gai Chase, between Cowan Creek and Pittwater, about 35 miles from Sydney Among them—all being engraved with the exception of a number of hands stencilled in red in a rock shelter—was a large carving deeply cut and about 9 ft in height, such as the author had not seen before in all his twenty years' experience The upper part of the figure is shaped like the head and bill of a platypus The arms are outstretched, showing a large boomerang in one hand, while the other points to a female The conjecture is made that it represents the totem deity of the Kuring tribe The female figure has her arms upstretched, with a circle attached to the left leg It is suggested that the site may have been used as a bora ground for the initiation of young men into the tribe

Egyptian Chronology—In *Ancient Egypt*, 1929, pt 2, Sir Flinders Petrie reopens the discussion of Egyptian chronology in the light of fresh evidence obtained from last season's excavations in Palestine at Beth pelet A long series of scarabs has been found which belongs to a large part—nearly the whole—of the Hyksos period From these it is now possible to deal with this age on a monumental basis Provisionally, the groups of scarabs have been classified in a succession of styles lettered from *A* to *W* In *A* and *B* the resemblance to good Egyptian work is very close, soon follow, in *C* and *D* figures, decomposed signs and the late Hyksos type of a name between vertical lines, and so forth to a final stage showing twists and side lines derived from decomposed *neter* signs Amid these changes down to the middle of the series are often various types which can be dated to known kings So close is the comparison that it is hard to believe that these types, decaying in the thirteenth Dynasty, were revived at a later date Indeed, the twelfth and thirteenth fashions had been so closely followed in the different types, that it is impossible to regard the Hyksos forms as belonging to a much later series This constitutes a strong case for the Hyksos age being contemporary with these two dynasties Turning to the literary record, if the lists of Manetho be used, it must be by placing the fifteenth and sixteenth Dynasties side by side with the thirteenth and fourteenth, Salatis, the first of the six great kings, probably entered the Delta at about the close of the reign of Amenemhat IV The Hyksos may have gradually occupied the Delta from the thirteenth to the fifteenth Dynasties and the whole of it up to Memphis by about the time of the twenty first king The recorded periods would then adjust themselves to show the thirteenth Dynasty ending in 1922 and the fourteenth at 1738, the seventeenth extending from 1738 to 1587

British Bird Ringing—The *British Birds* marking scheme has been by far the most thorough of British ringing agencies, and with the conclusion of 1929, when the record was reached with 25,243 individuals marked, a grand total of 258,791 has been accounted for during the twenty one years of the scheme In his summary of the year's work, H F Witherby mentions some interesting records—a ring ouzel ringed in Dumfriesshire recovered in Algeria, a Cumberland teal in the Gulf of Archangel, a Kinross wigeon two years later near Novgorod, Russia, and so on (*British Birds*, March, p 258, 1930) On the whole, the striking feature of the list with which he concludes his paper is the very small number of recoveries of ringed birds Most exceptionally, as in the case of the merlin, as many as 20 per cent have been seen again, but the general run of recoveries is 2 4 per cent and often the recoveries are negligible The low recoveries often affect unlooked for species Of 413 grey wagtails ringed between 1909 and 1928 only one has been recovered, and only one wood warbler out of 813 ringed, one sedge warbler out of 647, and not a single garden warbler out of 660 Of the common wren 2856 have been ringed in the same period and only 8 have turned up again The figures suggest that now certain birds might well be struck off the list, since they are unlikely to yield scientific data of value and they themselves cannot come scatheless out of the process

Chinese Amphibia—A useful check list of Chinese amphibia with notes on geographical distribution has been compiled by N Gist Gee and Alice M Boring (*Bull Pekin Soc Nat Hist*, vol 4, pt 2, p 15, December 1929) The list records 131 species, including one Apoda, 15 Caudata, and 115 Salientia An analysis of the ranges of the species shows that the amphibian fauna may be divided into a north China group with palæarctic affinities and a south China group with Indo Malaysian affinities Although there are only four genera peculiar to China, there are 84 endemic species, 53 being localised in mountain ranges, 13 on islands, and 12 in the northern mainland section There seem to be three mountain centres of species formation Szechuan, Yunnan and Fukien, and the situation of these areas means that most of the endemic species are in the south central region Both because of this and because the Indo Malaysian amphibian fauna is richer than the palæarctic, the amphibian fauna of south China is much more abundant than that of north China, but the wide range of the species in the latter area suggests that many problems of specific and subspecific forms may still have to be dealt with there

Value of Field Studies in Zoology—Dr S L Hora chose as the topic for his presidential address to the Section of Zoology of the Seventeenth Indian Science Congress at Allahabad in 1930, "The Value of Field Observations in the Study of Organic Evolution" (Calcutta, Asiatic Society of Bengal, 1930) This is a subject at which the author has worked for a number of years and to which he has obviously given much thought The aspect of field work chosen to illustrate the address is the structural modifications undergone by the fauna of torrential streams to meet the strenuous demands of the environment, and in particular those exhibited by the fishes The genus *Nemachilus* provides interesting parallel series of modifications of the 'air bladder' in correlation with diverse habitat preferences in swift streams and still lakes in different river systems The author puts forward a well timed plea against the enthusiasm of those who advocate experimental zoology as the solution of all problems, and claims with Kerr that "evolution is a philosophy of wild Nature"

New Species of *Amœba* with a Stigma—A Pascher (*Biol Zentralbl*, Bd 50, Heft 1, 1930) describes *Amœba stigmatica*, a relatively small species 0 03 to 0 05 mm in diameter, with two contractile vacuoles, zoochlorellæ and a large, grooved, bright red stigma The nucleus has a granular karyosome of moderate size No flagellate stage was seen, nor was division of the active amœba or holozoic feeding observed The reserves in the cytoplasm are fat and oil droplets

Encysted examples had a firm, light yellow envelope surrounding the contracted protoplast, the zoo chlorellæ and the stigma From one cyst issued a single amœba, but in another, division occurred and two amœbæ issued This amœba is markedly photo tactic probably due to the presence of the stigma, but the symbiotic algæ may also be a factor This amœba is to be regarded as a descendant of a chromatophore bearing flagellate The grooved type of stigma is found in only two groups of flagellates, the Euglenidæ and the Dinoflagellates, and the author considers the former the more probable line of origin This new amœba affords further evidence in support of the origin of the Rhizopoda from the Flagellata

Marine Mollusca off the West Coast of Ireland —The Fisheries Branch of the Irish Department of Agriculture has done much dredging off the west coast of Ireland since 1900, and an account by Anne L Massy of the mollusca procured—exclusive of the Cephalopoda Amphineura Nudibranchia Pteropoda and Heteropoda—has now been published (*Proc R Irish Acad*, vol 3, Sect B, No 13) The area dealt with lies between 49° N lat and 56° N lat, and between the 50 fathom and 1500 fathom lines, exclusive of the area to the east of the Fastnet Light Since the *Porcupine* expedition of 1869, dredging has taken place from time to time in different parts of the area, and to make the present paper more complete all records from these earlier researches have been included In all, 313 species are enumerated, mainly under the nomenclature of the Conchological Society's 'List' of 1929 Under each species are given the occurrences at fisheries branch stations, previous records distribution in space, vertical range, and fossil records, whilst a bibliographical list of references particulars of stations, and index of genera conclude the paper, which thus forms a most valuable contribution to a knowledge of the molluscan fauna of the seas off the British Isles

Transplanting Cereals —For several years past extravagant claims have been made of large increases in yield resulting from the transplantation of cereals *Landtechnik* (quoted in *Jour Min Agric*, March 1930) gives the results of records of German experiments obtained by the Reichskuratorium fur Technik in der Landwirtschaft In 146 experiments observed in 1929, the spacing varied from 20 cm × 20 cm to 35 cm × 35 cm, tillering in all cases being extraordinarily good The transplanted plots were 8 14 days later in ripening than those drilled in the usual way, and as the former also suffered from the dry period of the year, the yields may have been unfavourably affected thereby Only 32 4 per cent of the transplanted plots gave higher yields than the drilled plots, whereas 67 6 per cent showed lower yields The yield increases were between 0 and 69 2 per cent, less than half of the increases being greater than 30 per cent In no single instance was 100 per cent increase recorded It is considered that the value of the transplanting of cereals must be regarded as negative from the point of view of practical agriculture Nevertheless, in view of the fact that increases of about 50 per cent were obtained in certain properly controlled experiments, it is desirable that the investigations should be continued in order to determine the conditions of growth under which these yield increases occur, and this work is being carried on by the Landwirtschaftliche Hochschule, Berlin

Rainfalls Accompanying Volcanic Explosions —In the literature on volcanic explosions, there are numerous references to mud flows, and landslides that have their cause in heavy rainfalls, the alleged source of which is in condensed steam In the *Am Jour Sci* for February 1930, R H Finch examines critically the evidence bearing on the source of such rainfalls, the records of the 1924 explosion of Kilauea supplying most of the data for the discussion Rain falls do not accompany all volcanic explosions and the heaviest rains reported at Mt Pelée and Vesuvius did not immediately follow the maximum of activity On the other hand, the available records show good correlation between observed relative humidity and rainfall It is concluded that while light rains may well have had part of their source in condensed steam the main source must be the moisture of the surrounding air

Recent Spectroscopic Researches - The issue of the *Zeitschrift fur Physik* for Feb 10 (vol 60, Nos 1 and 2), which is devoted to publications from the University of Bonn, contains a number of important papers dealing with several branches of spectroscopy Extreme infra red work is represented by contributions from E Rutten and T Dreisch on absorption by thin sheets of metal and other substances P Lueg gives an account of improved methods for photography in the near infra red and he and Miss J Querbach describe some spectra obtained in part with the aid of the new technique Contributions to the measurement of standards of wave lengths are made by P H Brodersen and H Pressentin Other papers are by Prof Mecke and R M Badger, on the atmospheric absorption band of oxygen at 7600 A, by W Scheib, on the band spectrum of boron monoxide, which has been measured and analysed, and by W Kerris, on the spark spectrum of iodine The whole forms a notable addition to the literature of spectroscopy, and has evidently been largely inspired by Prof Konen and Prof Mecke

Tests of Tool Steels —In order to provide information as to the behaviour of tool steels when used as in average workshop practice an extensive series of tests has been carried out at the U S Bureau of Standards at Washington by Messrs H J French and T G Digges, who give an account of their results in the first 70 pages of the December issue of the Bureau's *Journal of Research* Their method consists in setting two tools at equal depths in the same tool holder and noting when the following tool begins to cut on account of the wear of the leader, and they investigate the effects of tool form, depth of cut, feed, cutting speed lubrication, composition of the steel and its heat treatment on the life of the tool They find that the life is inversely proportional to the tenth or twelfth power of the cutting speed, is not much influenced by the lubricant while of twelve elements added to chromium tungsten vanadium steel, only one, nickel, produced decidedly beneficial results on the life, copper had a slight, tin a greater, and arsenic and antimony decided, adverse effect

Automatic Thermostat —An automatic temperature control apparatus for experimental chambers heated by alternating electric currents, which claims to regulate to 1/100° C, has been introduced by Messrs Baily, Grundy, and Barrett of Cambridge A thermometer in the chamber has an adjustable platinum wire above the mercury with which the mercury on rising makes contact and so applies to the grid of a valve a suitable potential The anode current produced operates the main contact in the heating circuit, which may take a current of 10 amperes The filament, grid, and anode potentials are supplied by a small transformer on the alternating mains, and the power used is about 0 6 unit per day

Electrical Applications in Motor-Cars —In the *Journal of the Institution of Electrical Engineers* for

January, an interesting account is given by Prof Parker Smith of the progressive development of electrical applications to motor cars In the early days, any electrical accessories were added after purchase At the present time, they form an integral part of the equipment and are built into the chassis by the manufacturer Electric ignition, which is now universally adopted, was the earliest application Electric lighting also has gradually displaced the one time popular and originally more powerful acetylene lamp Batteries being introduced, a charging dynamo became a necessity This was followed by the starting motor now almost universally used on private cars and widely adopted on commercial vehicles The later introduction of other electrical devices such as electric horns, windscreen wipers, fuel pumps, and signalling devices was both simple and natural The author points out that, almost without exception, every piece of electric equipment for automobiles had to be developed against strong competition from non electrical alternatives The stage of development seems now to be passing, and signs of standardisation, with the consequent cheapening of the products, are making their appearance British manufacturers, backed by the British Engineering Standards Association, are making determined attempts to ensure interchangeability of parts wherever possible Since the beginning of the War, the modern magneto has been immensely improved and dual ignition is generally regarded as unnecessary Perhaps the question of 'glare' is the problem that has not yet been satisfactorily solved

Rauschelbach Current Meter—Particulars have reached us of a new electric current meter (Dr Rauschelbach's design) manufactured by the Askania Werke A G of Berlin Friedenau, which is intended for use in determining the direction and velocity of tidal, coastal, and marine currents by means of observations from a vessel riding at anchor It is claimed that accuracy of direction can be obtained within limits of 3° and velocities within a range of 0 05 to 3 mm The appliance consists of a frame with suspension cables, supporting the meter with its switchgear, spindle, current vane, propeller, contact box, loading weights, etc The meter is secured within the frame and rotates freely on the vertical spindle, to which are attached a multi bladed propeller and a controlling vane of the usual type The revolutions of the propeller are transmitted by worm gear to a contact disc in the contact box, and thence to the recording instrument which is kept on board The recorder is provided with fourteen pens, having fourteen corresponding electro magnets to actuate them each time the respective circuits are closed The first of these pens traces a time record on the chart, the second records the number of revolutions of the propeller, and the remaining twelve serve to show the direction of the current Testimony is adduced from the Königsberg Water Board to the effect that the meter has been satisfactorily employed for a year in the harbour of Pillau and adjacent waters Several instruments are also stated to have been in service during the summer of 1928 on the lower Elbe and outer Ems

Odoration of Town Gas—The possibility of making illuminating gas more powerfully odorous with the object of preventing poisoning through leakage is attracting attention, and a pamphlet on the subject has been published as No 6 of the *Abhandlungen aus dem Gesamtgebiete der Hygiene*, edited by Dr R Grassberger of the University of Vienna A large number of experiments made with various substances of sufficient volatility and powerfully odorous showed that the liquid hydrocarbons separating from compressed oil gas and the light oil pre-distillates of gas works were most suitable So long as it is impossible to transform the carbon monoxide of the gas into methane, it is suggested that the gas should be impregnated with the vapours of these materials

The Glass Electrode—The use of the glass electrode in potentiometric measurements is extending, and in this connexion the existence of a permanent potential difference across the glass film is of importance This disturbing effect has been investigated by MacInnes and Dole, who have studied its relation to the composition of the glass The January number of the *Journal of the American Chemical Society* contains a paper by these authors in which previous work is briefly mentioned and in which further experiments are described The most suitable type of commercial glass was found to have the composition SiO_2 72, Na_2O 22, and CaO 6 The potential at the surface of this glass changed quantitatively with the hydrogen ion activity up to *p*H values of 9 5, though this limit was lowered in strong salt solutions, Since the glass electrode is used in biological work, it is essential that these anomalies should be known

Molecular Weight of Casein—In view of the discordant results given for the molecular weight of casein, a new determination by Svedberg, L M Carpenter, and D C Carpenter by the ultra centrifuge method, and described in the January number of the *Journal of the American Chemical Society*, is of considerable importance Casein prepared by the Hammarsten method was found, in *p*H 6 8 buffer solution, to consist of a mixture of protein molecules of different weight An alcohol soluble casein was prepared from Hammarsten casein and was found to be homogeneous and probably a pure chemical individual The molecular weight was 375,000 ± 11,000 The molecule was not spherical and deviated from the spherical shape by about the same amount as found for several other proteins The same journal also contains a paper by Svedberg and Sjögren on the molecular weights of two vegetable proteins, amandin and excelsin, determined by the centrifuge method These were found to be 208,000 ± 5000 and 212,000 + 5000 at various *p*H values Both molecules are spherical with radii of 3 94 mμ and 3 96 mμ, respectively

Test of Low Temperature Carbonisation Plant—The Director of Fuel Research has tested, in accordance with the scheme in vogue, the Turner plant for the low temperature carbonisation of coal, erected at the Comac Oil Co, Ltd, Coalburn, Lanarkshire In this retort the coal is heated internally by steam superheated to nearly 600° Penetration of the charge by steam and heat is ensured by frequent and sudden alternations of pressure on the retort To achieve this, the retort is made practically gas tight with an ingenious system of valves, automatically controlled, which is claimed to be an essential feature of the installation A Scotch coal of feeble caking properties was carbonised in the test, lasting nearly 5 days, without serious difficulty The yields per ton were Coke 12 2 cwt, tar 19 2 gal, spirit from gas 1 7 gal, gas 2400 cub ft of calorific value 790 B T U/cub ft The coke was readily ignited and suitable for use in normal domestic grates although not entirely smokeless It is not clear how much would be saleable for this purpose Fuel would be consumed in producing and superheating the large quantity of steam required This, after condensation, yields much liquor (464 gal/ton) probably of a character not welcomed by sewage and river authorities

Frank Buckland and Fish Culture

THE first course of public lectures on fishery subjects under the Buckland Foundation was given on Feb 24, 25 and 27 at Grimsby, and on Mar 24, 25, and 26 at Hull, by Prof W Garstang, of the University of Leeds, who holds the appointment of Buckland professor for 1930 Prominent members of the fishing industry presided over the six meetings, including Sir George Moody, Councillor A Bannister, and Mr G L Alward in Grimsby, and Mr A Cargill, Mr Percy Ross, and Lieut Colonel Hudson in Hull

Prof Garstang devoted his first lecture to a sketch of Frank Buckland's interesting personality, parentage, and career, and his remaining lectures to the bearings of modern scientific work on the problem of 'farming the sea', a dream which Buckland cherished and on which his pen was busy up to a few days before his death The lectures will shortly be published by the Trustees of the Buckland Foundation, 43 Parliament Street, London, S W 1 In the meantime, the following abstract will indicate the ground covered

Rather more than a hundred years have fled since Frank Buckland's birth (1826) and nearly fifty since his death (1880) His father was the celebrated Dr William Buckland, Dean of Westminster, formerly Canon of Christ Church and the first professor of geology in Oxford , his mother had artistic gifts as well as a great interest in natural history In the sixties and seventies of the last century, Frank Buckland was in the height of his powers, and was tireless in pressing upon his countrymen the importance of fisheries to the national welfare and the need of fuller knowledge bearing upon them His death at the untimely age of fifty four years was entirely due to the desperate exertions he made in January 1878 to fulfil a late but urgent request of the New Zealand Government for an additional consignment of salmon ova He succeeded, but never recovered from the effects of the prolonged exposure to icy water and driving snowstorms which he endured on this occasion

At his death, Buckland left to the nation his Museum of Fish Culture (now at South Kensington) and a reversionary sum of £5000 with which to endow a professorship of economic fish culture By this term, as shown by numerous passages in his later writings, Frank Buckland meant something much wider than fish hatching, for which he had an early enthusiasm, and meant all knowledge bearing on the practice, maintenance, and advancement of the fisheries By endowing these lectures he provided a means, never more needed than at the present time, by which additions to knowledge, however acquired, might be sifted, put together, and brought forward for the consideration of the fishing industry and the general public

An atmosphere of natural history surrounded Frank Buckland from his cradle, and was continued during his school life at Winchester After graduating at Oxford, and undergoing a surgeon's training at St George's Hospital, he took up a surgical commission, like his greater contemporary, Thomas Henry Huxley, but in the 2nd Life Guards, instead of in the Navy His chief interests, however, continued to lie in the behaviour of animals, whether kept as pets in the Deanery of Westminster or as inmates of zoological gardens, menageries, shows, and aquaria, or at large in duck pond and trout stream He set out with a great admiration for John Hunter, and aspired to emulate him in the creation of a science of comparative physiology , but he lacked true scientific method, and, his pen running away with him, his writings soon lost all trace of such an aim, and assumed a very diversified character, in which the racy and humorous elements tended more and more to preponderate

The loss of both his distinguished parents, for whom he had a deep veneration as well as affection, and the writing of his father's "Life" in 1858, brought to an end this phase in Buckland's career, as represented by his "Curiosities of Natural History", and he sought opportunities of turning natural history into more practical channels He took up acclimatisation, then fish hatching (1861), resigned his surgeoncy (1863), started *Land and Water* (1866), and in 1867 was appointed an inspector of fisheries, after which date he devoted practically all his time and energy to fishery duties and problems

The tasks which fell to the salmon inspectors of those days were thoroughly congenial to him, and his efforts to clear the rivers of numerous obstacles to salmon migration were remarkably successful, his earnestness and imperturbable good humour being great assets in negotiations with millers and land owners His 'practical natural history' was rewarded by a gratifying increase in the yield of salmon fisheries in almost every river in which his recommendations were adopted

Buckland's career was cut short too soon for him to mature his views on the more complex problems of the sea fisheries, but the idea of 'farming' the waters, as agriculturists farm the land, took early hold of his practical imagination In the last words he wrote on fishery matters, only two days before his death, he referred to the North Sea as a potential "Great Fish Farm", which only awaited more knowledge before it, too, like the rivers, could be brought under conditions of 'cultivation', as opposed to those of mere exploitation So far, it must be admitted it is a farm in which Nature has done all the sowing and man only the reaping

In the immense progress of marine science since Buckland's time, however, the conditions for a possible farming of the sea have become much clearer, as well as the limits set by natural factors Chief of these is the demonstration of the limiting factors to the annual crop of plant life in the sea, on which the stocks of fish ultimately depend In the elucidation of these difficult and highly technical questions, the staffs of the marine laboratories at Plymouth and Millport have played a very distinguished part

The invisible floating pastures of green diatoms depend, like other plants, on sunlight and 'manurial salts' (nitrates and phosphates), and both factors are subject to great annual and seasonal variations The outburst of diatoms in the spring may be exceptionally early or exceptionally late, thus hastening or retarding the development of the floating animal life (plankton), on which all larval, and some adult, fishes depend for their existence As the different species of fish have their special breeding seasons, these accelerations and retardations of the plankton may correspond with, or fail to overlap, the seasons when the fry of particular fish are being hatched and are seeking food Moreover, there is a natural 'disharmony' between the tendency of diatoms to float and multiply in the illuminated upper waters, and the downward gravitation of the main sources of manurial salts Gales and temperature changes mix up the various water layers in winter, so that the year starts with an even distribution of the nitrates in the sea from top to bottom , but the spring outburst of diatoms quickly uses up the nutritive salts in the upper layers, and unless there are timely summer gales to bring up fresh supplies from the bottom, the diatom pastures rapidly dwindle, in spite of the increasing power of the solar rays

Thus arise good and bad years for the replenishment

of the stocks of fish, and, unless and until man devises the means of regularising the supply of nutrient salts in the surface waters, these natural fluctuations are inevitable and uncontrollable. Who can disperse the clouds below the sun, or modify the incidence of summer storms?

Science is not quite helpless even under these conditions, for, as the age of individual fishes can now be determined, the effects of good and bad years, when the data are adequate, can be traced to their causes, and can be followed in the actual stocks of fish through considerable cycles of years. It is thus becoming possible to predict from the age composition of a stock of herring, haddock, etc., in a given year and its predecessors, what it is likely to be in the ensuing season. In this way Mr. Hodgson, of the Lowestoft Laboratory of the Ministry of Fisheries, last September made a remarkably close forecast of the autumn herring fishery, and leaders of the industry have already expressed their appreciation of the commercial value of such forecasts. To be forewarned is to be forearmed, and may mean the annual saving of many thousands of pounds in an industry which requires large anticipatory provision of apparatus, stores, and personnel.

From the point of view of farming the sea, the magnitude of modern fishery operations is a fact of cardinal importance, since the collective power of the fishing fleets is no longer negligible in comparison with the blind forces of Nature. It was formerly thought that this power was merely destructive; but the problem is one of dynamics, not statics, and the destruction entailed by fishing is now known to be balanced by an increased rate of production. It is the quality rather than the quantity of fish that is changed by it. Like the destructiveness of Nature, that of the fishing fleets operates as a selective agency, and is creative of new conditions some of which are manifestly beneficial. It is possible that the hosts of herring have been actually increased in consequence of the elimination by trawlers of the large haddocks which feed upon their spawn. It is certain that the removal of old plaice favours the survival and growth of the young, the precise nature of the result depending also on a further factor, the greater or less amount of local reproduction. In the Cattegat and Baltic, where reproduction is limited, the effect of intense fishing is seen in a great increase in the growth rate, coupled with a reduction in numbers, thus raising the average size. A race of small, slow-growing and worthless fish has been converted into one of large, quick-growing and valuable fish, but it is feared that the rate of reproduction is insufficient to meet the steady reduction in numbers.

On the other hand, in the North Sea, with a high rate of reproduction, the effect of intense trawling is to increase the survival of the young and their emigration offshore, so that the increase of their growth rate is checked at a certain level by additional numbers. The increase of small fish in the catches, formerly regarded as evidence of 'over-fishing', is really the greatest safeguard against it, for it means that, however intense the fishing, the gaps are immediately filled from inexhaustible reserves.

If these arguments are soundly based—and the recent experience of post-War changes overwhelmingly supports them—the North Sea problem is reduced to the question of how to increase the average size of the fish without reducing the intensity of fishing. So far as the plaice is concerned, the answer is already available.

One of the first results of scientific investigation of the North Sea was to show that the Dogger Bank, with an area as large as Wales, lies outside the track of normal plaice migration, and yet possesses enormous reserves of the favourite food of this fish. The one unimpeachable method of raising the size of plaice in the North Sea is to utilise this great reserve for the purpose, and to transplant every year some millions of the small overcrowded and slow-growing fish from the coastal banks to this great feeding ground, on which it has been shown repeatedly that the plaice transplanted grow three, four, and even six times as rapidly as on their native shores.

Science is useless without enterprise. Great Britain looks to the traditional enterprise of the great Humber fishing ports to take up this matter as a commercial proposition. Let Grimsby and Hull take the first step towards cultivating the 'Great Fish Farm' which lies at their very door.

Opening of the Forest Research Institute at Dehra Dun, India

THE February issue of the *Indian Forester* is a commemoration number devoted to a detailed account of the opening of the new buildings of the Forest Research Institute at Dehra Dun, India. A brief announcement of this event has already appeared in NATURE (Nov. 16 and 30, 1929).

The new main building was opened by the Viceroy on Nov. 7, 1929. Perhaps the most important part of Lord Irwin's speech was his allusion to the work of the expert committee appointed under the presidency of Sir Chunilal Mehta "to advise them about the functions and policy of the Institute and the future of its activities". The report of this Committee was presented and made public last summer and the Viceroy explained some of its recommendations as follows: "In the report they made a number of most helpful suggestions and laid down, with admirable judgment and lucidity, the line of policy which should be pursued in the future. ... I am happy to be able to say that the bulk of their recommendations have already been taken up in consultation with Mr. Rodger and that we hope to give effect, in due course, to very many of them. We intend within the limits of our financial liability to give this Institute, now so finely housed and located, the scientific staff which it requires, and to omit or neglect no measure which we think will make for its continued success and greater usefulness.

"The Institute and the various allied activities of which it is the centre, must, as I see it, aim at the discharge of a double purpose. On the most effective utilisation of Indian woods, I have already spoken, but it is not less our desire to train Indian personnel in all the technical branches of forestry research work. The governing consideration must remain that of efficiency."

Mr. (now Sir Alexander) Rodger, Inspector General of Forests and president of the Forest Research Institute, in his address of welcome to the Viceroy and Lady Irwin, pointed out that Dehra Dun has been the centre for forest work since 1878, when a forest college was founded for training rangers and foresters. Forest research work has been in close touch with education since 1906, when the Research Institute was inaugurated, though, as a matter of fact, in two branches, chemistry and forest zoology, the ranger class had the benefit of lecture courses from research officers several years antecedent to 1906. Sir Alexander alluded to the enormous expansion in personnel since 1906. In the latter year there were five gazetted officers and one non-gazetted officer appointed to the charge of the six branches into which

forest research was subdivided. Each officer had a small clerical staff allotted. In 1929 the staff had expanded until the Institute now employs thirty-five gazetted officers, two hundred and twenty assistants and subordinates, and three hundred and fifty men on daily labour. It is this great development which necessitated the construction of the great buildings opened by the Viceroy on Nov. 7.

In 1906 no special accommodation was available. The first large building was erected at Chand Bagh and opened in 1914. It was confidently expected that this building would suffice for all possible requirements of the Institute for a number of years to come. The development of the forest resources of India made such strides during the War that the Industrial Commission pointed out in 1918 the necessity of expanding the Institute to meet the rapidly increasing demands of the country. The Commissioners advocated the increase of the number of research officers and stated that the equipment provided was entirely inadequate. These recommendations were accepted by both the Government of India and the Secretary of State and, in spite of later suggestions for cutting down the scale of the new proposals, they survived the ordeal. The workshops of the economic branch were completed and in working order in 1924 and the main building was occupied during the years 1926 and 1928. The total cost of the new establishments is close upon one million pounds.

The three most handsome rooms in the Forest Research Institute are the new library, in Andamans padauk, the large hall, all Burma teak, and the entrance hall, shisham and rosewood. Another room which is very effective is the office of the forest economist, which is panelled in poon (*Calophyllum*) from Madras. The other rooms are not so decorative, but, as Burma teak of good quality has been used throughout, they are mostly handsome as well as useful. A special feature has been made of the windows, with good lighting for laboratory work. There are six museums, with floor space of 26,000 square feet, and the ordinary rooms designed for laboratories and offices cover about 63,000 square feet.

In the grounds, besides the workshops of the economic branch are offices for the different branches and numerous residences of all kinds for the staff.

As at first arranged, the buildings at Chand Bagh were to be utilised as the training centre for the Indian probationers for the Indian Forest Service whose two years' course of training in forestry is now being given at Dehra Dun. It was perhaps too much to hope to keep Chand Bagh in the Department, even though so much forest history has grown up around it. The beautiful building is to be given up and it is to be utilised in the future for medical research work, while part of the new Institute building will be devoted to the educational requirements of the Indian Forest Service probationers.

The chief value of this commemoration number of the *Indian Forester*, for the future, will not be confined to the account of the opening proceedings of the new buildings. For the latter is followed by a valuable detailed account of the past history and development of the various branches of the Institute from the date of its inauguration in 1906.

Archæology from the Air in Central America

THE definitive account of the recent archæological reconnaissance by air in Central America, to which reference has already been made in our columns (see NATURE, Dec. 28, 1929, p. 995) appears in the April number of the *Geographical Review* (New York). The authors are Mr. Oliver J. Ricketson and Dr. A. V. Kidder, who acted as observers. The text is illustrated by a number of photographs taken by Mr. Ricketson and Mrs. Lindbergh. As previously noted, the leader of the expedition was Col. Lindbergh, who originally suggested the idea of the reconnaissance to the Smithsonian and Carnegie Institutions.

To enable their readers to appreciate the significance of the observations on the four flights which were made, the authors recapitulate the main divisions and distribution of the remains of ancient Maya civilisation. The oldest remains are found at Peten in Guatemala, whence the city-building activities of the Maya were carried to what is now British Honduras and Yucatan. The classic period of the Old Empire, lasting from about the beginning of the Christian era to 610, was followed by a migration to lands of which northern Yucatan became the most important. There a renaissance took place in the eleventh and twelfth centuries which is marked by the magnificent buildings of Uxmal and Chichen Itzá. Later, the Mexicanisation of Maya art and religion, after the calling in of the Nahua tribes, led to a time of vigorous growth and building activity followed by a hundred years of decadence which ended with the Spanish conquest.

A great deal of the country which was thus occupied is still unexplored. Short of cutting a way through the almost impenetrable bush, the only means of access are the paths of the *chichle* gatherers (*chichle* is the sap which forms the basis of chewing gum). Although these paths are gradually opening up the country, they still do not join, and the country lying between is unknown. As travel by bush path gives no opportunity for topographical observation, the general aspect, geographical features and contour of the Maya country are not known. As became apparent from the observations made on these flights, the existing maps are untrustworthy as regards the situation of natural features, existing settlements, towns, and ruins. Several unmapped natural features were recorded for the first time.

The flights began on Oct. 6, 1929, and a flight was made on each subsequent day up to and including Oct. 10. On the last day, however, comparatively little time was spent in archæological observation as the party flew to Havana and Miami. The flights were usually at an altitude of 500 feet, as this was found the best for observation, and the average speed was 85 miles per hour. The difficulties of observation owing to the density of the vegetation will be appreciated from the fact that on several occasions the aeroplane circled and recrossed known sites without the observers being able to 'spot' the ruins. It was desired to follow the great causeway which runs for at least fifteen miles from Coba, but although the exact spot at which it leaves the city was known, it could not be found.

The flight on Oct. 6 was from Belize to Merida, a distance as flown of 454.8 miles, the time taken being 5 hr. 21 min. Owing to the inexperience of the observers, observation on this flight was found difficult, but as time went on rapidity and accuracy were found to come with experience. After spending the night at Merida, the party returned to Belize on Oct. 7 by a slightly shorter route, ending with a flight along the coast, the distance covered being 373 miles in 4 hr. 23 min. On this flight, Chichen Itzá and Yaxuna were visited and a landing made at Lake Payegua. On Oct. 8 a flight was made to Flores, the return being by the southward of the Cockscomb range. On this journey Yaxha, where a landing was

made, Nakun, Tikal Lake, Peten, and Peten Forest were visited—443 miles in 5 hr 14 min flying The flight of Oct 9 to Cozumel, which occupied 5 hr flying time, was archæologically the most productive Not only did the party fly over sites already known, such as Tzibanché, an Old Empire site discovered by Dr Gann in 1927, but on several occasions ruins, pyramids, and buildings were sighted which were entirely unknown before Of these one was of considerable size After a night at Cozumel, flight was resumed to Coba, and thence, as previously stated, to Havana and Miami

In summing up the results of the experiment, the authors express their opinion of the great advantages of the exploration of this country by air There is obviously an immense advantage to be gained in time In twenty one hours of archæological flying, they covered about 1780 miles The time it would have taken to cover the same country on the ground is incalculable Some areas could not have been reached at all, while others could have been reached only by a large and expensively equipped expedition Not only, therefore, does this method of exploration make possible geographical and topographical observation otherwise impossible, but the advantage in time to the excavator if a practical method of organising transport could be devised would be an enormous gain Both the authors and Col Lindbergh are convinced that an air survey of the region is both feasible and desirable It is estimated that a complete survey would occupy about five months Col Lindbergh is prepared to give every assistance in his power towards carrying out this project In the interests of American archæology, it is to be hoped that a generous benefactor may be found to finance the undertaking

University and Educational Intelligence

Oxford —The proposal to use the money set free by the sale of the present site of the Radcliffe Observatory for establishing an observatory in South Africa is advocated by the Savilian professor of astronomy, Prof H H Turner The grounds on which the plan commends itself to astronomers are stated by him to be chiefly two first, the extreme uncertainty of the Oxford climate, together with the facilities which now exist for rapid communication, and secondly, the importance of supplying fresh centres of observation in the southern hemisphere, where much work will have to be done to catch up with that already carried out for the northern skies The disappearance of the old Radcliffe Observatory will be regretted on sentimental grounds, but there would appear to be no question of the scientific advantages to be gained by the present proposal of the trustees

Applications for grants from the Dixon Fund for scientific research must reach the Academic Registrar of the University of London, South Kensington, S W 7, by May 15

Grants from the Thomas Smythe Hughes and Beaverbrook medical research funds of the University of London will shortly be made Applications should reach the Academic Registrar of the University, South Kensington, S W 7, by June 15

Senior industrial bursaries for assistance in practical training in engineering are being offered by the Company of Armourers and Brasiers and applications for them should be sent before May 31 to the Clerk of the Company, Armourers' Hall, 81 Coleman Street, E C 2

Historic Natural Events

April 27, 1682 Thames Flood —Under this date, Viscountess Campden wrote to her daughter, the Countess of Rutland "Never was such flodds known as has bine here, howses drowned and pore children drowne in theare cradels swimen up Fleet Bridge, and there taken up, and tables and hogeds full of beare and all washed away, and peoppele geting up to theare lofts and hole heards of hogs drowned, and so Roger Pratt comeing from Norfolke narely escaped drownding and logers in Fleet Dich drowned, that never such a flood was known, that it is impossable for me to returne till the watters falls"

April 27, 1894 Earthquake in North-east Greece —A week earlier, on April 20, a strong earthquake occurred in north east Greece, by which 224 persons were killed and houses were damaged over an area of 1760 sq miles The earthquake of April 27 was much stronger, houses being overthrown within an area of 3000 sq miles With this earthquake, crust movements occurred along a fault, about 35 miles long, running in a constant west north west direction parallel to the Gulf of Eubœa The Plain of Atalante, on the north east side of the fault, was shifted slightly to the north west, and depressed by an amount, usually small, but in places by as much as 5 feet

April 29, 1697 Thunderstorm —A violent thunderstorm occurred over Snowdon and in north west England, accompanied by hail, over a tract two miles wide and sixty miles long Hailstones weighed five ounces, and broke nearly all the windows, killed many fowl, poultry, and sheep, and destroyed the green corn

April 29, 1882 Gale —During the progress of a deep cyclonic system north eastwards across England, a gale occurred which was unusually severe for so late in the spring The gale blew from south west and west, and was general over the south and east of England and the north of France Much damage was done to the young spring foliage, the leaves being in many cases completely blackened, as though singed by fire This effect was probably due to mechanical injury caused by the high wind, but was attributed by some observers to the action of sea salt, crystals of which were clearly traceable upon many of the leaves

April 29, 1892 "Malartic" Cyclone —A very violent tropical cyclone struck Mauritius, the centre passing directly over Port Louis, where an enormous amount of damage was done An interesting feature was the overthrow of "Malartic" monument, a column 49 feet high built of stone blocks The upper part of this column, 26½ feet high, and 5 feet 3 inches across at the base, was overthrown by the wind, and it was afterwards calculated that the wind pressure to achieve this must have reached 142 lb per square foot, equivalent to a velocity of more than 200 miles per hour The highest wind velocity recorded at the Pamplemousses Observatory was 123 miles per hour

April 30, 1575 Frost and Flood —Holinshed records that "all the lochs, rivers, and all manner of other waters were frozen in Scotland, from the beginning of November till the latter end of April, and when the frost brake and the snows melted, there was such a flood flowing over all the plains even to the roots of the mountains as the like had not been seen Furthermore, when the same shrunk and went away, in the mud and slime there was such a sort of frogs left that when they were dead and began to putrefy the air was so infected that many deadly diseases

issued, whereof great numbers of the inhabitants did perish " In France the winter was equally severe, no man living had seen the like, and the snow fell in such quantity that the forests were inaccessible and people could not obtain wood Horses and men perished in great numbers, and the cold was succeeded by famine and pestilence which, it is said, destroyed almost a third of the population Similar effects were felt in Italy and Germany, and the Rhine was frozen for a long period

May 1, 1594 Wet Summer began—The weather was unusually wet and unseasonable from the beginning of May until July 25, this was followed by dearth This is believed to be the summer described in "A Midsummer Night's Dream", Act 2, Scene 1

> The ploughman lost his sweat, and the green corn
> Hath rotted ere his youth attained a beard
> The folds stand empty in the drowned field
> And crows are fatted with the murrain flock,
> The nine men's morris is filled up with mud

May 1, 1908 Intense Rainfall in Panama—A downpour of unrivalled intensity occurred at Porto Bello (Panama) Owing to the indistinctness of the autographic record caused by the excessive accumulation of water, there is some doubt as to the exact amount, a conservative estimate gives 2 48 inches of water in five minutes, but another figure often quoted is 2 47 inches in three minutes Either figure constitutes the heaviest fall of rain ever recorded in that time

May 3, 1605 Glacier Advance—The inhabitants of Chamonix presented a demand for reduction of taxes, on account of the damage done by "glaciers, the river Arve and other torrents" The damage was due especially to abnormal advances of the glaciers

May 3, 1849 Cloudburst—At 5 30 P M during a storm of thunder, lightning, and hail, an enormous body of water rushed down a gully in Bredon Hill, North Gloucestershire, towards the village of Kemerton The stream was broad and impetuous, carrying everything before it On reaching the residence of the Rev W H Bellairs, of Kemerton, it broke down a stone wall which surrounded the garden, burst through the foundation of another, made a way for itself through the dwelling house, and then carried off a third wall of brick six feet high The garden soil was washed away, and enormous blocks of stone and debris from the hill left in its place It flowed through the house to the depth of three feet for an hour and forty minutes The neighbouring railway was so deeply flooded as to delay the express train by extinguishing the fire of the engine The course of the torrent could easily be traced up the hill for more than a mile, to a barley field of five acres, the greater part of which was beaten down flat and hard, as if an enormous body of water had been suddenly poured out upon it Beyond this there were no signs of the fall of water to any great amount

May 4, 1697 Hailstorm—A violent thunderstorm, accompanied by a south westerly gale, began at Hitchin, Herts, at 9 A M and continued until 2 P M Some of the hailstones which fell during the storm were reported to be thirteen or fourteen inches in circumference; the hail split great trees and destroyed several hundred acres of wheat, and at Sir J Spencer's, 7000 panes of glass were broken On the same day a noteworthy hailstorm occurred also in Staffordshire, in which the hailstones were reported to be nearly twelve inches in circumference. The ground was torn up, and there were at least 100,000 cartloads of hailstones

Societies and Academies

LONDON

Geological Society, Mar 12—**R W Pocock** The age of the Midland basalts Data bearing on the age of the various igneous masses in the Upper Carboniferous are brought together The conclusion is reached that the Shropshire and South Staffordshire basalts are of the same general age namely, Yorko Staffordian, whether extrusive or intrusive A volcanic belt is known to traverse the Midlands from Hanter and Stanner in Radnorshire to the Ashby Coalfield area The main movement along this zone took place in Yorko Staffordian time, and the basaltic masses in question are, without exception, situated along it—**Thomas Robertson** The origin of the Etruria Marl The Etruria Marl Group of the Upper Coal Measures in the Midlands is mainly composed of chocolate coloured to purple clay, mottled with green, yellow, etc, alternating with greenish sandstones (Espley Rock) In appearance and composition the Etruria marl strongly resembles the denudation products of basalt and basic tuff, and further examination shows that it contains fragments of basalt, that its position in the geological sequence is the same as that of the Coal Measure vulcanicity in the Midland Province, and that it is best developed in those portions of the basins of deposition towards which the denudation-products of the Midland basalts would flow

PARIS

Academy of Sciences, Mar 17—**S Winogradsky** The synthesis of ammonia by the soil *Azotobacter* The cultivation of this organism in a mannite medium has, with one exception (Kostytschew), never given rise to ammonia The author now shows that if means be taken to increase the pH of the medium to between 8 and 9, ammonia can be detected in the atmosphere above the culture—**Giuseppe Cesàro** was elected a *Correspondant* for the Section of Mineralogy—**Vladimir Bernstein** Correction concerning the series of Dirichlet—**Baule** A method of navigation based on automatic route tracing—**V Schaffers** The earth connexion of lightning rods—**Maurice Lambrey** The two normal states of the NO molecule For a layer of nitric oxide of constant thickness, the optical density of the γ bands is proportional to $p^{1\ 81}$, whilst the optical density of the β-bands is sensibly proportional to the pressure—**Mlle Jacqueline Zadoc-Kahn** The magnetic double refraction of para azoxyanisol at temperatures above the point of disappearance of the mesomorph state The measurements were made with the Bellevue electromagnet in a field of 40,700 gauss The high value of the magnetic double refraction found and its rapid variation with temperature agree with the views of G Föex—**A Blanc** The photo-electric phenomena of solutions of potassium ferrocyanide—**Adolphe Lepape** and **Marcel Geslin** The radioactivity acquired by materials exposed to the action of atmospheric agents The materials examined, lead, zinc, slate, and deposited dust, were obtained from the roof of the Collège de France, and all emitted a very absorbable radiation (α-rays) The activity of the lead is higher than that of the zinc, but practically equal to that of the slate It is concluded that the radioactivity is due to substances derived from the air—**Jean Savard** The ultra-violet absorption spectrum of aniline vapour.—**Al Yakimach**: Complexes of quadrivalent manganese cyanide Description of the preparation and properties of a potassium manganicyanide, $K_4Mn(CN$ [illegible] **Lespieau** and **Deluchat**, Paradivinylbenzene paradiacetylenylbenzene—**Georges Brus** and **G Pe[illegible]blanques** The fixation of ozone by benzene linkages

Brussels

Royal Academy of Belgium, Oct 12 —Cl Servais The geometry of the tetrahedron (4) —**Victor van Straelen** The Jurassic decapod crustaceans of eastern Greenland —**M Dehalu and P Swings** Note on a method of star photography based on the measurement of the opacities of photographic tracks By a slight adjustment of the mechanism driving the equatorial telescope, the image of each star is made to appear as a short line of about 1 millimetre in length, and the opacity of this line is measured with a recording photometer The method should prove especially useful for the fainter stars —**P Gilard and P Swings** A simple method of determination of the absorption of glasses in the ultra violet region of the spectrum The method described has been applied to five glasses It is shown that the addition of nickel oxide makes the glass more permeable to the ultra violet, and that increased transparency results from the replacement of calcium oxide by barium oxide —**E Asselberghs** Note on the marine fauna of the Gedinnian of the Ardennes —**F Govaert** Contribution to the study of the nitration of *o* fluorbenzoic acid The main product of the nitration of *o* fluorbenzoic acid is the 1 2 5 fluornitrobenzoic acid, about 5 per cent of the 1 2 3 isomer being also formed —**R H J Germay** The equation of Gauss —**Maurice Nuyens** A new method of integration of the gravific equations with spherical symmetry —**D V Jonesco** Some problems relating to a formula of recurrence or to a finite difference equation —**Th Lepage** Certain differential forms associated with equations of the Monge Ampère type arising from the calculus of variations —**Raymond Defay** The thermodynamical study of surface tension affinity and adsorption velocity —**Louis van den Berghe** Note on deglutition in the Cyprinidæ

Rome

Royal National Academy of the Lincei, Dec 1 —Guido Ascoli Approximate representation of a function by means of linear combinations of given functions —**E Bortolotti** Geodetic co ordinates along a line (2) —**B de Finetti** Integration of functions with aleatory increment —**G Sansone** Surfaces applicable to surfaces of constant mean curvature New demonstration of Ricci's theorem —**B Segre** Existence of distinct continuous systems of plane algebraic curves with given Plueckerian numbers In continuation of the author's recent communication on questions relating to the existence and dimensions of continuous (irreducible) systems of plane algebraic curves with given characters, it is now shown that there may exist several distinct complete continuous systems (even of different dimensions) of irreducible algebraic curves with given Plueckerian characters Certain applications of the theory of continuous systems are also considered —**M Picone** The interval of indetermination of Poisson's summation procedure for Fourier's and Laplace's systems —**Pia Nalli** Rigid displacements and generalised derivatives —**A Gelfond** A theorem of G Polya —**G. Boaga**: Simple rapid topographical procedures —**N Passerini**: Minimum temperatures at different small heights above the ground Observations made at the Meteorological Observatory of Pisa between June 1, 1924, and June 30, 1927, show that, with rare exceptions, the minimum temperature during the twenty four hours increases from 0 05 m to 2 m above the ground The extreme differences may exceed 3°, and in one instance (Jan 3, 1925) reached 4 5° In most cases the minimum readings at 0 05 m and 1 m show a greater difference than those at 1 m and 2 m —**Rita Brunetti** Variations of crystalline polychroism under the influence of the electric field —**E Segrè** Anomalous dispersion in band spectra —**A Ferrari and C Colla** Crystalline structure of neutral carbonates of cobalt and nickel Normal cobalt carbonate exhibits rhombohedric structure of the 'calcite' type, the dimensions of the unit cell, which contains four molecules being $a = 5\ 91 \pm 0\ 005$ A, $\alpha = 103° \ 22'$, the density is 4 24 Unlike the cobalt salt, natural normal nickel carbonate has never been found, although nickel compounds are more widely diffused than those of cobalt Preparation of nickel carbonate by various synthetic methods employed has not been found possible —**V Zagami** Muscular phosphogen in fish Experimental results are given which indicate the existence of a direct relationship between the phosphogen content of the muscles of fishes and the degree of activity and muscular strength as regards swimming In other words, migratory and strong swimming fish contain more phosphogen in their muscles than stationary fish or those that swim less Moreover, the caudal region always contains more phosphogen than the cranial region The more highly the dental apparatus of the fish is developed, the greater is the proportion of phosphogen in the masseter muscle in comparison with that in other muscles of the same organism —**R Savelli and N Soster** Provocation of monophylly in *Cannabis sativa* L by means of wounds

Sydney

Royal Society of New South Wales, Dec 4 —M B Welch (1) Some mechanical properties of Australian grown *Pinus insignis* (2) Whilst considerable variation occurs, the wood is by no means brittle and devoid of strength as is commonly believed Whereas the denser Gosford wood closely resembles in every respect pitch pine, the lighter and milder South Australian wood possesses the characteristics of the clear and sugar pines It seems, therefore, that by proper grading, *Pinus insignis* can be obtained for most of the purposes for which imported softwoods are used, provided, of course, that it can be obtained in length free from defects —(2) Some properties of red satinay, *Syncarpia Hillii* This is a close textured reddish coloured timber occurring in large quantities on Fraser Island, off the Queensland coast, but is little known on the Sydney market The wood is very durable, borer and white ant resistant, and is also remarkably difficult to burn The weight, about 52 lb per cubic foot, precludes its use for many purposes, but where this factor is not important the wood should be useful It works crisply and does not splinter easily, and with the added advantage of fire resistance should make an excellent flooring timber, whilst figured logs are very suitable for veneer The wood requires little filler and readily takes a high polish It is, however, inclined to be brittle and is not suitable for positions requiring toughness —**L L Waterhouse and W. R. Browne** Note on an occurrence of quartzite containing common opal and chalcedony at Tallong, N S W The rock overlies a Permo-Carboniferous sandstone

and is itself overlain by Tertiary basalt It is considered probable that the quartzite was originally a Tertiary sand derived from the underlying sandstone, and that silica was added mainly from volcanic sources The cementing material is in the forms of quartz, common opal, and chalcedony, and there are veinlets through the rock lined with opal and filled with chalcedony The order of deposition, quartz, opal, chalcedony, was probably one of decreasing temperature, no sign of a transition from opal to chalcedony was observed —G D Osborne and H G Raggatt Some interesting geological faults in the vicinity of Branxton, N S W The stratigraphy of the Upper Marine rocks exposed in a railway cutting near Branxton is described and a detailed account of the faults intersecting these beds is given There are nine faults, seven being of overthrust type The displacement in each case is small A consideration of the strike, dip, and general features of the thrusts leads to the conclusion that they were produced in Post Palæozoic time when the area was subjected to the crustal compression which culminated in the development of the Hunter Overthrust —Miss J Chalmers and J C Earl Studies on the hydrolysis of cellulose (1) By using a boiling 5 per cent solution of hydrogen chloride in methyl alcohol, it has been possible to accomplish a graded breakdown of cellulose triacetate Properties of some intermediate products are placed on record —Francis Lions (1) Some trimethoxy quinoline derivatives 1 Acetyl 2 4 dimethyl 5 6 7 trimethoxytetrahydro quinoline and 1 acetyl 2 4 dimethyl 6 7 8 trimethoxytetrahydro quinoline have been synthesised from 3 4 5 trimethoxy aniline and 2 3 4 trimethoxy aniline respectively by condensation with acetylacetone followed by ring closure, reduction, and acetylation —(2) Researches on indoles (1) 6 Acetylamino eugenol methyl ether obtainable from eugenol methyl ether by nitration and reduction followed by acetylation, readily yields a dibromide ($C_{13}H_{17}O_4NBr_2$), which on treatment with concentrated alcoholic potash is converted into 2 methyl 5 6 dimethyoxindole — H Finnemore and C B Cox Cyanogenetic glucosides in Australian plants (2) An examination of the 'native fuchsia' has shown that the cyanogenetic glucoside, which was present in the remarkably high amount of 10 per cent in a sample of air dried leaves from Queensland, is identical with prunasin, which has been previously prepared by the controlled hydrolysis of amygdalin, and is found in Nature in the drug *Prunus serotina*

Diary of Societies

FRIDAY APRIL 25

FARADAY SOCIETY (at Chemical Society), at 3 15 —Annual General Meeting

ROYAL SOCIETY OF MEDICINE (Medicine Section) at 5 —Cinematographic Demonstration by Dr L G Rowntree Ganglionectomy in Chronic Arthritis —Prof Dixon and Dr G N Myers The Curative Action of Digitalis in Toxæmia.

INSTITUTION OF MECHANICAL ENGINEERS, at 6 —W Nithsdale The Design and Results of a 600 lb per sq in Boiler Installation

ROYAL SOCIETY OF MEDICINE (Epidemiology Section) at 8 —Prof S L Cummins Some of the Clinical and Pathological Factors underlying Mortality Rates in Tuberculosis

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub Centre) —S W Melsom A N Arman and W Bibby Surge Investigations on Overhead Line and Cable Systems

SATURDAY, APRIL 26

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Newcastle upon Tyne), at 2 30 —G E Tansley The Value of the Economiser in Present Day Boiler Installations — Paper open for further discussion —Notes on a Winding Accident at Mainsforth Colliery, C Howson

BRITISH PSYCHOLOGICAL SOCIETY (at University College), at 3 —Dr O A Oeser A Critical Examination of Kohler s Gestalt Psychology — G C Grindley Psychological Factors in Peripheral Vision —Miss M D Vernon A Photographic Study of Eye Movements in Reading

MONDAY, APRIL 28

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4 30 —Rev Dr H C Morton The Concept of Evolution in the New Psychology

INSTITUTE OF ACTUARIES at 5 —P N Harvey Notes on the Relative Mortality of Married Men and on an Experiment in Forecasting Mortality over a Limited Period

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —Prof A E Richardson Architects Drawings of 1800–1850

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8 —F Coleman Buried Mandibular Teeth with Crowns in Occlusion —Mrs. May Mellanby Some Further Investigations on Man and Animals, into the Causes of Dental Disease, with Special Reference to Factors Controlling the Resistance of the Dental Tissues to Harmful Agencies

TUESDAY, APRIL 29

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4 30

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5 —Prof J J R. Macleod Diabetes as a Physiological Problem (Oliver Sharpey Lectures) (1).

INSTITUTION OF CIVIL ENGINEERS, at 6 —E T Ward The Navigability of the Lower Danube.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7 —J Durward Air Photography Surveys. —Dr F M Hamer and O Bloch The Optical and Photographic Properties of Certain Dyes of the Thionine and Related Types —A S. Newman Demonstration of H and D Exposure Machine —O. J. Wilkinson Concerning Photography in the Gangetic Delta

ROYAL ANTHROPOLOGICAL INSTITUTE (jointly with Folklore Society), at 8.30 —Dr M Gaster Roumanian Art and Handicraft in Relation to the Balkan Peoples.—Mrs. Murgoci Description of the Collection of Roumanian Folklore Objects on Exhibition

WEDNESDAY APRIL 30

GEOLOGICAL SOCIETY OF LONDON, at 5 30.—Emily Dix and Dr A. E. Trueman Some Non Marine Lamellibranchs from the Upper Part of the Coal Measures —Emily Dix The Flora of the Upper Portion of the Coal Measures of North Staffordshire
NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at 17 Fleet Street) at 5 30 —Major E A. Marples Ancient Civilisations
ROYAL SOCIETY OF ARTS at 8
EUGENICS SOCIETY (at Royal Society), at 8 30.—Dr C P Blacker Birth Control Research and Practice in Europe.
ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30 —Prof H Young The Advantages of the Perineal Route in the Treatment of Various Diseases of the Prostate
ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY — Dr W E Patterson Resistance of Electrodeposits to Corrosion, with Special Reference to Cadmium and Zinc

THURSDAY, MAY 1

LINNEAN SOCIETY, at 5 —E B Worthington On the Movements of Plankton in the African Great Lakes —Dr G P Bidder On the Attitude of a Hexactinellid at the Bottom of the Sea, as compared with that assumed in Museum Jars and Monographs —M Burton Glass Sponges.
ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5 —Prof J J R. Macleod Diabetes as a Physiological Problem (Oliver Sharpey Lectures) (2).
ROYAL INSTITUTION OF GREAT BRITAIN, at 5 —Annual Meeting
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—R H Fowler Some Recent Advances in the Electron Theory of Metals (Kelvin Lecture).
CHEMICAL SOCIETY, at 8 — R J W Le Fevre and E E Turner Orientation Effects in the Diphenyl Series. Part VIII The Nitration of 4 4-difluorodiphenyl — Miss D I Fox and E E Turner The Scission of Diaryl Ethers and Related Compounds by Means of Piperidine. Part IV Elimination of Halogen Atoms and Scission Reactions during Substitution Processes
ROYAL SOCIETY OF MEDICINE (Tropical Diseases Section) (Annual General Meeting) at 8
INSTITUTION OF CIVIL ENGINEERS (Birmingham and District Association) (at 6 Corporation Street, Birmingham).—Annual General Meeting

FRIDAY, MAY 2

ROYAL SOCIETY OF MEDICINE (Otology Section) (Annual General Meeting) at 10 30 A.M —Papers by Prof M Bourdillie and G J Jenkins
ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5 —Annual General Meeting
ROYAL SANITARY INSTITUTE (at Town Hall, Tunbridge Wells), at 5 30 — Dr F C Linton and others Discussion on The Maternity Home as a Health Asset —H. T Taylor and others Discussion on Can the Slum be Abolished?
INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7 —C W Marshall The Metering Arrangements for the 'Grid Transmission System in Great Britain (Lecture).
INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 —Major A. W Farrer Empire Free Trade and the Engineer
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7 —Informal Meeting
GEOLOGISTS ASSOCIATION (at University College), at 7 30 —A A Miller and J S Turner The Lower Carboniferous Succession along the Dent Fault and the Yoredale Beds of the Shap District —R. G S Hudson The Carboniferous of the Craven Reef Belt The Namurian Unconformity at Scaleber Nr Settle.
FARADAY SOCIETY (at Chemical Society), at 8 —Prof G Wiegner On Coagulation (Lecture).
PHILOLOGICAL SOCIETY (at University College), at 8 — Anniversary Meeting
ROYAL SOCIETY OF MEDICINE (Anæsthetics Section) (Annual General Meeting), at 8 30 —Dr R J Clausen Ethylene Anæsthesia.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9 — H. E Wimperis A Study of the Phenomenon of Spin in Airplanes

PUBLIC LECTURES

MONDAY, APRIL 28

FISHMONGERS HALL, E C 4, at 3 —W L Calderwood Modern Views on Salmon Hatching (Buckland Lectures) (1).

TUESDAY, APRIL 29

FISHMONGERS HALL, E C 4, at 3 —W L Calderwood Modern Views on Salmon Hatching (Recent Results from Canada) (Buckland Lectures) (2).
UNIVERSITY COLLEGE, at 5.30 —Dr J C Flugel The Methodology of Happiness
GRESHAM COLLEGE, at 6.—W H Wagstaff Geometry (Succeeding Lectures on April 30, May 1 and 2)

WEDNESDAY, APRIL 30

FISHMONGERS HALL, E C 4 at 3 —W L Calderwood The Sea and River Life of the Salmon (Buckland Lectures) (3).

THURSDAY, MAY 1

ST THOMAS'S HOSPITAL MEDICAL SCHOOL, at 5.30.—Dr H Leslie-Roberts Some Biological Aspects of the Human Skin (Succeeding Lecture on May 2)

FRIDAY, MAY 2.

UNIVERSITY COLLEGE, at 5 — Prof B. Ashmole History of Ancient Sculpture

EXHIBITION

APRIL 28 TO MAY 3.

EXHIBITION OF ROUMANIAN PEASANT ART (under the Auspices of the Royal Anthropological Institute and the Folk Lore Society) (at 52 Upper Bedford Place, W C 1), from 10 30 A M. to 5 30
April 29, at 8 30 —Dr M Gaster Roumanian Art and Handicraft in its Relation to the Balkan Peoples

DISCUSSION

APRIL 25 AND 26

FARADAY SOCIETY (at Chemical Society).—Optical Rotatory Power
Friday April 25, 2 30 to 7 P M —Prof T M Lowry Introductory Paper

(a) The Physical Basis of Optical Rotatory Power

Prof P P Ewald Introduction to Physical Theories of Natural Optical Activity
G Temple Wave Mechanics of Optical Rotation and of Optically Active Molecules
Prof R de Mallemann On Molecular Theory and the Calculation of Natural Rotatory Power
Dr W Kuhn The Physical Significance of Optical Rotatory Power
Dr K Wolf The Principle of the Free Rotation of Optically Active Molecules
Dr H G Rule The Influence of Polar Substituents on the Optical Rotatory Power of Organic Compounds

(b) Apparatus and Methods

Dr R. Descamps Methods for the Measurement of Natural Rotatory Power in the Ultra Violet Region of the Spectrum
Prof T M Lowry and Dr G Owen Note on the Calculation of Dispersion Equations

Saturday, April 26, from 10 A M to 1 15 P M, and 2 30 to 4 P M

(c) Rotatory Power of Solutions

Prof A. Cotton The Existence of Racemic Compounds in Solution and the Application of Circular Dichroism to the Synthesis of Active Compounds.
Prof E Darmois Salt Effect and Rotatory Power
Prof G Bruhat The Absorption and Rotatory Dispersion of Solutions of Tartaric Acid
Dr P C Austin The Rotatory Dispersion of Tartaric Acid and its Derivatives.
Dr R Lucas The Origin of the Variations in the Rotatory Power of a Compound
Prof T S Patterson The General Behaviour of Optically Active Compounds from a Single Point of View
G Owen The Effect of Concentration on the Values of the Dispersion and Rotation Constants for Solutions of Camphor in Methyl Alcohol

(d) The Chemical Aspects of Optical Rotatory Power

Dr W H Mills Molecular Dissymmetry
Prof R Betti Relationship between Rotatory Power and Chemical Constitution
Dr J Kenyon Relation between the Rotatory Powers of the Members of Homologous Series.
Prof J Read Optical Superposition
Dr J Kenyon and Dr H Phillips Some Recent Developments in the Study of the Walden Inversion

ANNUAL MEETING

MAY 1 AND 2

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers).
Thursday, May 1, at 10 A M —Presentation of Bessemer Gold Medals to Dr E Schneider and Dr W Rosenhain
Prof W A Bone L. Reeve, and H L Saunders An Experimental Inquiry into the Interactions of Gases and Ore in the Blast-Furnace Part II Carbon Deposition at 450 C and its Influence upon the Ore Reduction Equilibria between Gases and Ore at 650 to 1000 C
F Bainbridge Developments in Fuel Economy at Skinningrove
At 2 30 —R Whitfield Single Sheet or Thin Pack Normalising, or Heat Treatment *versus* Box Annealing of Sheets
E Mort Tin and Sheet Mill Rolls Their Treatment, Performance, and Premature Failure in Service
Sir H C H Carpenter and J M Robertson The Metallography of some Ancient Egyptian Implements
J A. Jones Chromium Copper Structural Steels.
Friday, May 2, at 10 A M —Announcement of Award of the Andrew Carnegie Research Scholarships for 1930-31 Announcement of Award of the Williams Prize to W E Simons.
Dr W Rosenhain and C H M Jenkins Some Alloys for Use at High Temperatures Nickel-Chromium and Complex Iron-Nickel Chromium Alloys. Part I —C. H. M Jenkins, H J Tapsell, C R. Austin, and W P Rees Part II
J L. Haughton and M L. Becker Alloys of Iron Research Part IX The Constitution of the Alloys of Iron with Silicon
M L Becker Carburising and Graphitising Reactions between Iron-Carbon Alloys, Carbon Monoxide, and Carbon Dioxide
A L. Norbury and E Morgan The Effect of Melting Conditions on the Microstructure and Mechanical Strength of Grey Cast Irons containing Various Amounts of Carbon and Silicon
A. R. Page and J H Partridge The Properties of some Steels containing Chromium
D Brownlie The History of the Cementation Process of Steel Manufacture. Part I —Baron de Laveleye Part II
S. Maita The Corner Ghost in Steel Ingots

SATURDAY, MAY 3, 1930

British Aviation

THE peaceful penetration of all fields of thought and activity by the spirit and method of scientific inquiry is well illustrated in the extent to which eminent politicians, and ministers of the Crown, now frequently refer to the need for relying on scientific knowledge for our material salvation This is strikingly exemplified in the speech delivered by Mr F Montague, Under Secretary of State for Air, on Mar 18, in presenting the Air Estimates Gone is the old tradition of regarding decimal points as mere 'damned dots' of no importance, and in its place we have the 'new style' speech bristling with technical details that one might expect only from the mouth of the most hard headed expert as a justification to democracy for the expenditure of its hard earned money In a sense this change should occasion no surprise The Air Force is a new wing, and, unlike the Army and the Navy, has no long evolutionary history behind it It is an upstart that has won eminence by a series of scientific and technical strokes It can only be developed by technical knowledge it can scarcely even be conducted without it

The total of last year's estimate was £16,960,000, as against for this year a total of £17,850,000, an increase due in the main to the provision of up to date equipment, essential alike for safety and efficiency, the growing needs of civil aviation, and outlay in scientific research It can scarcely be contended that the air policy of Great Britain is anything but limited and unprovocative If consideration is given to comparative air strength, and to the trend of air expenditure of such powers as France, Italy, and the United States of America, it becomes clear that the Air Force of Great Britain is substantially exceeded in first line strength by these three other powers In this connexion it should be borne in mind that our overseas garrisons, in the Middle East, and in India, make a much greater call than those of other countries On the basis of metropolitan strength our standard is half-power approximately, compared with our nearest neighbour In reply to a question by Sir Samuel Hoare on April 16, the number of aeroplanes maintained by the respective nations, now, and five years ago, were stated to be

	1925	1930
Great Britain	630	780
France	1280	1310
U S A	750	950
Italy	600	1100

The extension of the Air Force is no mere

expansion in the ordinary sense To an increasing degree it is being used in the military field in substitution for ground forces, with a consequent considerable economy No other nation has yet pursued this policy of replacement to the extent to which Great Britain has done The change wrought by this kind of transformation is well illustrated by the case of Aden, where for the last two years there has been an air squadron of twelve machine strength and a total complement of 200 men, in replacement of one British and one Indian battalion of infantry with a total strength of about 16,000 Even as a mere aid to transport the effect of the aeroplane is of no mean order During the Palestine riots the prompt arrival of fifty soldiers by air did much to stem the movement Aircraft were used to drive off attacks by Arabs on isolated Jewish colonies before the arrival of ground reinforcements, in fact, according to Mr Montague, as an instrument for quelling insurgents in almost inaccessible regions of the Far East, the Air Force has been invaluable

The multitude of non military uses to which these aircraft have been put is almost incredible emergency assistance in cases of a medical and surgical character, particularly in India, rescues on British coasts and in the Middle East, warnings of floods in India, survey photography, participation in the anti locust campaign in the Sudan, fishery protection against poaching by foreign vessels on the east coast of Great Britain, co operation in the search for overdue fishing craft after gales These are some of the diverse activities that the Air Force has been called upon to perform Meanwhile, numerous reconnoitring flights are being undertaken across Africa, from north to south, with the object of trying out weather conditions for flying, and to examine the possibility of maintaining prearranged time tables under adverse conditions In one such test flight, aircraft from Cairo, after a journey of 11,200 miles, returned late by five minutes only on the scheduled time

The part of the Under Secretary's speech, however, that dealt with the more purely scientific side could have been understood by only a small fraction of his hearers The Minister explained in detail a large number of the highly technical problems that are being undertaken under the heads of research and development at various research stations He described, for example, the scientific nature of the problem of noise in aircraft, the analysis of its source, how it is measured, and the investigations that are being pursued with the object of reducing it He explained the nature of aerodynamic interference of aeroplane parts, and its effective wastage of horse-power, and he went on to describe in scientific terms the method of air tunnel testing of models, and its limitations as regards scale-effect This enabled him to justify the expenditure on a larger wind-tunnel and a new high pressure tunnel that are being constructed, and to explain their underlying principles Engine research, wireless rotating beacons for direction finding, and many other new scientific developments, also found their place in a remarkable speech

To scientific men in Great Britain it is especially gratifying to realise that their work, in its most technical form, has penetrated into the First Chamber in the land If, however, the House of Commons is to maintain itself, in these difficult circumstances, as a stage for critical and intelligent discussion, it is vital that members of that body who possess a scientific training should meet on common ground It is to be hoped that this may be provided by the new Parliamentary Science Committee

The Platinum Group Metals in South Africa

The Platinum Deposits and Mines of South Africa By Dr Percy A Wagner With a Chapter on the Mineragraphy and Spectrography of the Sulphidic Platinum Ores of the Bushveld Complex, by Prof D H Schneiderhohn Pp xv + 326 + 38 plates (Edinburgh and London Oliver and Boyd, 1929) 21s net

IN this book we have a complete history of the platinum group of metals from their genesis and mineralogy to the mining companies that exploit them Dr Wagner—and one realises with deep regret that this is the last time we shall receive such another work from his hands—speaks with authority, the authority that comes alone from personal experience He also secured the services of Dr Schneiderhohn, who contributes a valuable chapter abounding in admirable photo micrographs on the mineragraphy, spectrography, and genesis of the platinum bearing nickel-pyrrhotite ores of the Bushveld Complex In addition to plates, there are 37 text figures

Production of the platinum group of metals began in South Africa in 1921 when the recovery of 'osmiridium', a concentrate composed of several minerals, was begun in earnest in the Far East Rand The distribution of the 'osmiridium', principally derived from the Main Reef Leader, corresponds very nearly with that of the gold, but

at the best (in Modderfontein 'B') was only 1 oz per 1212 tons of conglomerate milled in 1924 It is entirely a by product to the winning of the gold In the central part of the Transvaal, however, the matter is different, for in 1925 the discoveries in the norite of the Bushveld Complex were made, a rock series which "probably contains in the aggregate more platinum than all the rest of the earth's crust accessible to man" Hence it is with this "vast composite body of plutonic and volcanic rocks" that Dr Wagner's book is for the greater part concerned

In general characters the Bushveld Igneous Complex is well known to students of African geology it is a basin shaped sheet or lopolith, 2 3½ miles thick and wonderfully differentiated into sheets and lenses simulating stratification Of these layers, the Merensky horizon, most important in the Rustenburg district, claims a large section of the book, which is dedicated with an obvious regard to its discoverer The Merensky Horizon contains the Merensky Reef', a pseudo-porphyritic pyroxenitic diallage norite, occasionally "almost uncanny" in the regularity of its dip and strike In many places 'chrome bands' are important features of the horizon This occupies six chapters, and it is impossible to sum up in brief space the immense amount of detail with which these are crowded It deserves six chapters, since Dr Wagner concludes its deposits are "among the world's greatest concentrations of mineral wealth"

Dr Schneiderhöhn's contribution to our knowledge of the nickel pyrrhotite ores is also very detailed The elaboration of the research is shown by the method employed It was found that microscopic work failed and ordinary analytical procedure proved impracticable to ascertain which minerals contained platinum and to what extent Accordingly, isolation of individual grains was effected by means of a motor driven drill resembling that used by dentists and minute fragments bored out under the microscope These were then vaporised in an arc lamp and the ultra violet part of the spectrum obtained by the use of a quartz spectrograph It was found that the chalcopyrite (the last sulphide to be formed) and millerite contained no platinum, which was present in the nickeliferous pyrite, pyrrhotite and pentlandite, these also containing cobalt Other results of interest are recorded, for which the reader is referred to the book

A short chapter is devoted to the Great Dyke of Southern Rhodesia, and it is thought that the small quantity of platinum and associated pebbles of chromitite of the Somabula field near Gwelo were derived from it In a few pages the seemingly disappointing nickel copper occurrences in the gabbro norite (a phase of the Karroo dolerites) of Insizwa and Tabankulu, and the more unusual ones of the Waterberg district in the central Transvaal, are described In the latter, the metal is found in quartz lodes along faults which cut felsites and tuffs of the Bushveld Complex, and is remarkable for its extremely erratic distribution, some assays giving extraordinarily high figures, "probably the highest" ever known

The book concludes with short accounts of mining methods and mining companies, marketing conditions, and costs of production, among which one notes that to produce 1 oz of platinum from the rocks of the Merensky Horizon costs about £6 the average content is roughly 5 dwt per short ton

It is somewhat surprising to read that approximately 70 per cent of the world's total platinum supply is used for jewellery, whereas before the War it was employed for technical purposes For the latter, substitutes have now been found

This is a book for geologists and mining engineers alike, and will doubtless remain for long the standard work on its subject

JOHN PARKINSON

Political Science

Research in the Social Sciences its Fundamental Methods and Objectives By Robert Ezra Park, Allyn Abbott Young, Clark Wissler, Robert Emmet Chaddock, Robert Sessions Woodworth, Roscoe Pound, Arthur Meier Schlesinger, John Dewey, Charles Austin Beard Edited, with an Introduction, by Wilson Gee Pp xi + 305 (New York The Macmillan Co, 1929) 8s 6d net

THIS book is a series of more or less authoritative essays on the several branches of social science and exhibits wide variation in merit, ranging from vague meandering through wordy labyrinths leading nowhere, up to real sublimity and noonday clearness of thought A sample of the labyrinthic uncertainty meets us at the very outset in the first essay, wherein Teggart is said to have stated the difference between history and the other sciences in one "fine phrase" He said "Science deals with objects, entities, things, and their relations, history concerns itself with events" One could, of course, debate until doomsday on such

a theorem, either for or against, without tolerable approach to a satisfactory, definite, and agreed solution No very clear light is thrown on the matter by the further cryptic utterance "Events happen, things do not" Hence we may conclude that science deals with things that do not happen! All this may be fine phraseology, but does not appear very helpful to the hopeful student struggling to make his way over the wide and troubled seas of sociology Moreover, the above quotation from Teggart is supposed to note the difference between history and the "other sciences", and this would seem to imply that history itself is a science Whence it follows that one particular science, history, deals with events that happen, whilst the other sciences treat of things that do not happen! Let us find what solace we can in this methodological labyrinth

Is history a science? Taking one wild leap over all the intervening essays on economics, anthropology, statistics, psychology, jurisprudence, history, and philosophy, we come to the last one, on political science, by far the best of the whole series, both in vigour and clearness of thought and in helpful and stimulating suggestiveness Alighting breathless after a long jump, the above query greets us Prof Charles Austin Beard says

> "Ever since Newton discovered the law under which the stars swing in their orbits imaginative thinkers have toyed with the possibility of reducing history to a science, and thus, automatically, the scattered and disjointed operations of mankind grouped for convenience under the head of politics"

Many great thinkers and the scientific spirit of the modern age have fed this ambition Henry Adams said that every professor who has tried to teach the doubtful facts we now call history must have felt that, sooner or later, he or another would put order in chaos and bring light into darkness Does it really matter very much? It all turns on our definition of science, and we have had to abandon every attempt to be very precise or inelastic in any definitions anywhere Whether or no we can bring history and therefore politics within the orbit of true science, there must always be a vast borderland where one hovers between science and no science or between science and philosophy, a region that must be closely scrutinised by all men

Prof Beard very ably discusses some of the difficulties in the path of recognising political science as such These seem to consist mainly in the first place in unsuitable materials to work on, and secondly in biased minds to work with Looking back over the political literature of the past two hundred years, he thinks that the major part of it, even of the greatest writers, is conspicuously partisan in spirit, designed to defend some existing political order or to discredit it in the name of something that is thought to be better, and "if such be the state of our literature, what can be said of the state of our minds", a confused mix up of convictions, prejudices, kinks, predilections, hunches, grouches The first difficulty is probably contained in or a corollary to the second, and the defective mind has presided over all the works of the greatest political thinkers at least for the past two hundred years Possibly, if we could glance backward two thousand four hundred years instead of only two hundred, and thus include Aristotle, we might luckily find at least one mind capable of rising above narrowness and prejudice But, taking the lesser sweep of backward vision, is it really the fact that all our writers and political orators within that period have suffered from these mental infirmities? Must we thus stigmatise such men as Burke, Chatham, Milton, or John Locke? Perhaps they have not been strictly scientific in the sense in which we understand the term to day, they have at all events been above or in advance of the general level of political thinking in their time, they have exhibited in a high degree political wisdom and sagacity, though whether this is the same thing as political science we need not stay here to inquire, and they have made wonderful contributions to the practical task of building up that noble edifice, the British constitution, and in enunciating the principles of sound government

Prof Beard admits that these real or imaginary defects, both in the materials requisite for constructing a science of politics and in the mental equipment available for the purpose, are not peculiar to the political and social sciences, they have been met with in the purest of the physical sciences, and do not necessarily and completely inhibit the ultimate hope of achieving a true science of politics, if we really are desperately anxious to make politics scientific in form and spirit A more serious difficulty, according to the author, is the utter futility of such a science, that is, if it is to attain to any sort of capacity for prediction, able to trace the trajectory of future political events Could, for example, political happenings have been safely predicted in any university in Germany in regard to the period 1910–20, without placing the professors under imminent risk of being

stoned or burnt by an enraged populace? Also that which is plotted in the curve would be inexorable "If we could get enough knowledge to make a science of politics, we should imprison ourselves in an iron web of our own making" We could not by any effort prevent or change anything in the prognosis

Waiving the question whether such inexorable predictability is a necessary quality of genuine science, must we cease our search for sufficient knowledge to make a science of politics for fear that we should thus be self condemned to feverish arachnidal activity and become hopelessly enmeshed in iron webs? Reasoning on the analogy of astronomy, one could easily reach a *reductio ad absurdum* Astronomical eclipses are predictable and inexorable, but we do not call such knowledge useless or set it up as an argument against the admission of astronomy to the realm of science In the political sphere, where phenomena are much more under human control, especially in view of the tremendous powers now placed in the hands of modern governments, it does not seem that prognosis, if attainable, need always be inexorable, or at least, if we could not change coming events we could possibly in some measure provide for or against them, or even introduce modifying factors

The kernel, however, of Prof Beard's essay is much more important and less controversial than these preliminary excursions He maintains very justly that what is really needed to day is creative thinking in the political sphere, and it is immaterial whether the results of such thinking are called political science, theory, philosophy, descriptive politics, or merely political thought We very urgently need intelligence applied to political data, and the main questions are What is intelligence? How can it be developed and enriched? What are the conditions favourable to its exercise on the data of politics? We are treated to a brilliant disquisition on the subject of intelligence in which the so called American intelligence tests are reduced to absurdity, and even the President of the United States is severely handled and called upon to explain himself President Hoover had recently ventured to include the following very innocent-looking little contribution to political science in an address to the engineering profession

"The engineers have contributed a great purpose in the United States—a purpose that is applicable to all branches of public life, not only their service but the engineers' mode of thinking by which there must be determination of exact facts, followed by a proper presentation of these facts in their proportional weight before any determination is made of either public or private issue That should be the basis of government action"

This might well pass as a general description of scientific method, but Prof Beard finds it bristling with difficulties when applied to politics, questions the terminological precision of nearly every word, and pulverises the whole statement with a heavy barrage of dictionary references

No, there is no science of politics, and there is not much room even for the application of scientific method It remains to consider the most favourable conditions for that hard creative thinking which seems to be the only thing left to us Among these leisure and freedom are of primary importance though not always essential, and they do not necessarily induce thought The intellectual atmosphere of the universities is not always favourable and might well be improved in various ways

"There are in the university too many charming friends who must not be offended, too many temporal negotiations that call for discreet management, too many lectures to be delivered, too many promotions requiring emphasis on the amenities of life rather than on its thinking processes, too many alumni eager to apply in 1928 what they learned in 1888, too much routine, not enough peace, too much calm, not enough passion, above all too many sacred traditions that must be conserved, too many theories, not enough theory, too many books, not enough strife of experience, too many students, not enough seekers Yet with all its handicaps to thought the university must supply the training for most of our political thinkers, and with all its limitations it furnishes the most favourable climate for creative work in America"

Practical experience with government as a going concern is desirable if it can be combined with aloofness from its immediately practical ends and freedom from financial or commercial entanglements or other interests One may add as a final stimulant to creative political thinking a clear apprehension of the goal aimed at and of some of the problems which call now for urgent solution Prof Beard propounds several of these, and his list is remarkable in the height and depth of its range If, as Edmund Burke said in regard to the conciliation of the American colonies, the mere attempt would be an undertaking that would ennoble the flights of the highest genius, so the mere contemplation of some of these momentous problems, on which depends the destiny of mankind, may well stir the mind and imagination to the supremest exercise of thought—the first essential in any effective action W G LINN CASS

The Sea and all that in it is

The Seas our Knowledge of Life in the Sea and how it is Gained By Dr F S Russell and Dr C M Yonge Pp xiii + 379 + 127 plates (London and New York Frederick Warne and Co, Ltd, 1928) 12s 6d net

THIS handy volume, comprehensive and competent, illustrated generously and luminously, is easily the best of the smaller books dealing with the sea and all that in it is The only English book that can hold a candle to it is Sir John Murray's little volume in the Home University Library, but it is much smaller and necessarily restricted in its illustrations With larger treatises, the best of which is "The Depths of the Ocean" by Murray and Hjort, the present compact volume does not compete, but the gist of the matter is all here, and the whole story of oceanography is admirably told

We congratulate Dr Russell and Dr Yonge on a first class piece of work, neither too popular nor too technical, a book of wide vistas, illumined with biological ideas It is written *con amore*, and we find the freshness and sparkle of the sea in its pages It is one of the most successful of recent ecological books, not only in its grip and clearness, but also because it is written educatively, building up from the familiar to the extraordinary, and from the general to the detailed, yet all as if the authors were thoroughly enjoying themselves, as their readers certainly do

After a general introduction on man's intellectual struggle with the problems of oceanography, "The Seas" starts with the life of the shore, the depths, and the open waters There are chapters on the swimming animals and the drifting animals, while the strange byway followed by borers is separately discussed Coral reefs prove as fascinating as ever, and then comes a fine chapter on colour and phosphorescence A discussion of different modes of nutrition among marine animals is followed by chapters on sea water and on the oceanic changes that are correlated with the seasons The authors pass on to methods of oceanographical research, and then come several predominantly practical chapters devoted to fisheries, shellfish industry, fishery research, and the diverse products of the sea Great restraint is shown throughout, for many of these subjects are very apt to run away with their expositors

It is difficult not to be extravagant in praising the well selected illustrations, many of which, including the coloured plates, are due to Mr W J Stokoe, who displays brilliant skill It is not only that the illustrations are beautiful and fresh, we wish especially to praise their educativeness They do not merely adorn the tale, they continue it The altogether admirable volume, which we wish to recommend unreservedly to all interested in the sea, is appropriately dedicated to Dr E J Allen of Plymouth, the inspirer of so many investigations in marine biology

Our Bookshelf

Die Rohstoffe des Tierreichs Herausgegeben von Ferdinand Pax und Walther Arndt Lieferung 2 Pp 161 400 18 gold marks Lieferung 3 Pp 160 12 gold marks (Berlin Gebrüder Borntraeger, 1929)

THE second part of this interesting work is composed of five chapters The first chapter is devoted to a consideration of the shells of molluscs as ornaments, amulets, as material for the preparation of cameos, as money, trumpets, lamps, etc The second chapter deals with the electrical deposition of metals on the exterior of animals such as snakes, the sea horse (*Hippocampus*), etc, by which successful permanent preparations are possible, and in an appendix the method of impregnating similar animals with paraffin wax in order to obtain dry preparations for museum purposes is briefly described The following chapter is on animal substances employed in powdered form as grinding or polishing materials, as tooth powder (for example, cuttle bone), and on skins, such as those of fishes used in smoothing and polishing ivory and other materials The chapter on insect galls describes the principal kinds of galls found in commerce, with analyses of the more important

The final chapter of this part is on colouring matters of animal origin, especially cochineal and the purple from the hypobranchial gland of certain molluscs An account is given of the history of these purple dyes, the constitution of one of which was determined by Friedlander, who prepared from 12,000 specimens of *Murex brandaris*, collected at Trieste, 1 4 gm of the purple dye and showed it to be a brominated indigo (dibromindigo) An adequate account is added of the production, preparation, and nature of sepia

The third part of this work is concerned entirely with the formation, extraction, qualities, and uses of the numerous forms of fat, oil, and wax, and of shellac Details are given of melting points and other physical properties and of the chemical constitution of many of these substances, and reference is made to the more usual adulterants and to the methods by which their presence may be ascertained

Of most of the substances dealt with in these two parts, there is an adequate historical account as well as particulars of the amounts of many of them exported or sold in given years, and the areas principally concerned in their preparation and in their use At the end of each section is a helpful bibliography

The Atom By Prof G P Thomson (The Home University Library of Modern Knowledge) Pp 252 (London Thornton Butterworth, Ltd, 1930) 2s 6d net

THE needs of the general scientific worker and the scientifically minded layman wishing to acquire a general knowledge of the advances and spirit of contemporary physics are very fittingly met by Prof G P Thomson's admirable little work The author has, in a short compass, presented an up-to date survey of physical theory and its bearing on chemistry with an extensiveness which would not be suspected from the title Starting with the spectrum and not forgetting cosmic rays, the reader is led through the fundamental laws of chemistry to the electron, isotopes, positive-ray analysis, crystal structure, and radioactivity to energy units, the conception of the quantum, and its development on the older theory

The most interesting part of the book is, however, that devoted to the recent wave theory of de Broglie, its development by Schrodinger, and the ideas underlying the electron wave The clear logical treatment throughout is assisted by a variety of happily chosen analogies A surprising number of topics come under notice, the reader will not look in vain for reference, necessarily superficial, to Heisenberg's uncertainty relation, Pauli's principle, the work of Davisson and Germer on the electron wave, Dirac and Darwin's work on the spinning electron, and Eddington's recent treatment of $hc/2\pi e^2$ The modifications of the older Bohr orbit scheme necessitated by the wave mechanics are explained, and the rôle of the electron in chemical theory is interpreted The book concludes with some considerations on the philosophical aspect of modern physics

Mathematics has been entirely avoided, the author confining himself mainly to those concepts which lend themselves to physical interpretation Due prominence is given to the fundamental part played by probability The reader will not appreciate the co ordination and development of Heisenberg's matrix mechanics and Dirac's analysis with the wave mechanics, these being unsuited to verbal explanation are wisely omitted The possibly one-sided view resulting is largely offset by the clarity of the wave picture A difficult task has been accomplished in a manner which will repay the study not only of the non specialist but also of the general scientific worker who has no wish to be lost in a mathematical fog N M BLIGH

The Year Book of the Scientific and Learned Societies of Great Britain and Ireland a Record of the Work done in Science, Literature and Art during the Session 1928–1929 by numerous Societies and Government Institutions Compiled from Official Sources Forty sixth annual issue Pp vii + 413 (London Charles Griffin and Co, Ltd, 1930) 18s net

Is this to be the last issue of this useful annual? Unless further support is received the publishers announce that they cannot continue its publication, at least in its present form, and it is proposed to economise by printing only the titles of papers which have been published as well as read We doubt, however, if this would enable the publishers to reduce the price of the volume substantially and in these days of heavy expenses it is the high price which, we believe, prevents a wider sale If the "Year Book" as it is cannot continue, we would suggest an annual volume omitting all the lists of papers Such a classified directory giving the names and addresses of learned societies and including, as now, their officers, brief particulars as to meetings, publications, and conditions of membership, would be useful and the information could be kept thoroughly up to date if the volume was issued about May For the present, however, we must be grateful to the publishers for continuing their efforts and also to the officers of societies who have given the time and trouble to enable the "Year Book" to retain its official character

Joy in Work By Henri de Man Translated from the German by Eden and Cedar Paul Pp 224 (London George Allen and Unwin, Ltd, 1929) 8s 6d net

THE English title is to be preferred to the original German, "Der Kampf um die Arbeitsfreude", for joy in work is spontaneous, not the result of struggle An interesting thesis is somewhat marred by extravagant phrasing, insensibly we think of "the devil rebuking sin" when the author inveighs against German books where "the old grist is reground into a new and jawbreaking terminology", let the following from "Joy in Work" suffice— "certain kindred antinomies in proletarian characterology", which doubtless well expresses the Teutonic original The subject is treated under the aspects of "Impulse" and "Hindrances" to such joy, and it is based on reports from workers, in response to a questionnaire furnished by the author He discusses medieval craftsmanship and modern mechanised labour, the merits and demerits of payment by time and by results, and distinguishes the factors that influence Teutonic psychosis from those that affect the Anglo Saxon races He wisely remarks that "payment by the piece need only endanger the quality of the product when piecework rates and minimum wages are so low that the worker has to speed up immoderately in order to earn a subsistence", and suggests that the owner's profits should "increase only in proportion to the increase in the workers' wages" P L M

Gmelins Handbuch der anorganischen Chemie Achte Auflage Herausgegeben von der Deutschen Chemischen Gesellschaft *System Nummer 59 Eisen* Teil A, Lieferung 1 Pp 224 (Berlin Verlag Chemie G m b H, 1929) 33 gold marks

THE section of Gmelin's 'Handbuch' dealing with iron (Part *A*) is an ambitious work to which eight specialists have promised to contribute The 224 pages now issued include a remarkable historical bibliography covering 59 pages, with nearly 2000 references, about 120 pages on the occurrence of iron, and in conclusion some 40 pages on the preparation of pure iron in various forms

Age of the Earth

I HAVE just finished reading a most interesting book on "The Universe Around Us", by Sir James Jeans It opens up a complex and abstruse subject with admirable clearness, so that even a geologist possessed of very little mathematics can find his way through it without too much difficulty The ease with which in this brilliant book millions of millions of stars are marshalled and their history outlined for millions of millions of years inspires no little awe and a large amount of envy in the breast of a plodding geologist who keeps to the solid earth If the book contained only the inspiring visions of an astronomer in regard to the origin and the fate of the universe around us a geologist might refrain from comment, but at several points the history of the earth and its inhabitants is touched upon, giving him a right to a word of criticism

Sir James in a page or two suggests that the earth began about 2,000,000,000 years ago as a globe of intensely hot gas, which gradually cooled down, becoming first a liquid, then plastic, and finally an outer crust solidified, "rocks and mountains forming a permanent record of the irregularities of its earlier plastic form" Life probably began on the earth about 300,000,000 years before the present

A generation ago, when Lord Kelvin laid down the law as to geological time, this allowance would have seemed very liberal, but the discovery that the age of certain rocks can be determined by an analysis of the radioactive minerals they contain has completely changed our point of view 2,000,000,000 years is decidedly too short a time for Pre Cambrian history if the earth began in a gaseous form, and life existed far earlier than 300,000,000 years ago

These points are easily proved by a brief study of the Grenville Series of Ontario and Quebec and of the Laurentian granite and gneiss which have erupted through it, since radioactive minerals are found in pegmatite dikes connected with the granite

AGES OF PEGMATITE IN ONTARIO AND QUEBEC

Localities	Determined by T L Walker [1]	Determined by H V Ellsworth [2]
Parry Sound	1,274,000,000 years	1,179,000,000 years
Villeneuve	1,293,000,000 ,,	1,189,000,000 ,,
Cardiff Tp	1,239,000,000 ,,	1,299,000,000 ,,
Butt Tp		1,130,000,000 ,,

The localities are scattered over 200 miles from west to east, and it will be observed that the age of the pegmatites does not differ greatly at the various points and that the two analysts are not far apart in their determinations We may conclude that the uraninites of the pegmatites were formed about 1,230,000,000 years ago

The pegmatite dikes are the latest phases of the molten granite which heaved up the rocks of the Grenville Series into domes forming important mountain chains which covered many thousand square miles, and the Grenville Series must have been solid rock long before this took place

The Grenville rocks are now crystalline limestones, gneisses, and quartzites, but were originally ordinary limestones, shales, and sandstones, which were deposited as limy material, mud, and sand in a shallow sea

The series is very thick according to Dr Adams, who measured 17,824 feet in one section and 94,406 feet in another, and to the age shown by the radioactive minerals must be added many millions of years for the deposit of a great geological formation, its consolidation, and the thrusting up of the widespread Laurentian mountains

But we are still far from the beginning Before the Grenville sediments could be laid down the earth's crust must have been firm and solid to form shores and sea bottoms of a permanent kind, and must have been cool enough to allow rain to fall and rivers to bring down mud and sand into the sea If the earth ever passed through a stage of heat and plasticity, that was completely over before the beginning of the Grenville sea, and the water was cool enough to allow algæ or other lowly plants to thrive, since in places the sediments contain several per cent of carbon, now in the form of graphite

Life had already appeared in the sea

The Grenville rocks have been chosen for this study because they are well known and are dated by analyses of radioactive minerals, but they are probably some what surpassed in age by the Keewatin, which is mainly volcanic, but with important amounts of sediments, and the Coutchiching, which is wholly sedimentary No uraninites have yet been found in the granites which penetrate them

Taking all of these formations together, we have a known area of 1,000,000 square miles of cold and rigid rocks with well established lands and seas in North America 1,300,000,000 or 1,500,000,000 years ago, with no suggestion of physical conditions fundamentally different from the present

The oldest rocks in Brazil, South Africa, Australia, India, Scandinavia, and Scotland, judging from what I have seen of them, include similar sediments to those of the Grenville and Keewatin in Canada, though not on so broad a scale In Holmes's interesting discussion of the "Age of the Earth", the Lower Pre Cambrian of West Australia is stated to be 1,260,000,000 years old, which fits well with the age of the Grenville

There were, then, solid land surfaces not too warm for lakes or seas to exist in all the continents in the earliest times known to the geologist, and there is, in fact, no geological evidence that the world ever was molten If our globe passed through intensely hot gaseous, liquid, and plastic stages, the cooling had run its course completely many millions of years before the pegmatite veins penetrated the Grenville sediments, and the cold continents had undergone at least one major mountain building revolution at an earlier time than 1,230,000,000 years ago

Since then the earth has not been cooling down, but has kept its surface temperature surprisingly uniform, though with minor variations, including several ice ages The carbon and limestone in the earliest rocks suggest lowly plant life in the waters from the very beginning of known geological history, and the Pre-Cambrian geologist is inclined to be a uniformitarian, and to ask the astronomer if the first quarter of the world's history was really so wild and turbulent as he describes it, when the later three quarters were so temperate and uniform

May not the earth have been built up of cold particles such as now reach us by the million from space, and may it not have escaped entirely the white hot stage of the nebular theory? Is it not possible that the hot gases cooled rapidly into innumerable solid particles which later came together to make the earth? The tiny scattered asteroids and meteorites suggest some such process, and this would provide

the cold earth which the Pre Cambrian geologist requires

If the astronomers cannot provide a cold process of world building, they must allow the geologist a much longer time than 2,000,000,000 years to condense the hot cloud of gas into a solid world with continents and basins cool enough for the Grenville sea with its algæ

Recombination of Electrons and Positive Ions in the Upper Atmosphere

A METHOD of obtaining the recombination co efficient of the electrons and ions in the upper atmosphere can be arrived at by the use of some recent radio telegraphic observations The method depends essentially upon the measurement by radio methods of the maximum density of electrons in the layer at various times of the night after the ionising agent, the sun's ultra violet light, has been removed

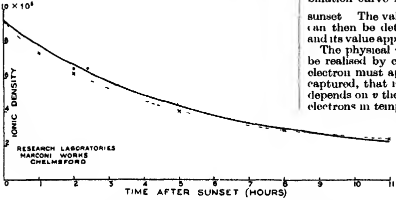

FIG 1 —Full line observed curve, broken line, recombination curve

A ray of frequency ν sent out by a radio transmitter at an angle of elevation θ will not be bent back to the earth again unless there are sufficient free electrons in the layer, and the relation determining the number of electrons N required is

$$\cos\theta = \frac{R+h}{R}\sqrt{1-\frac{Ne^2c^2}{\pi m\nu^2}}$$

N is electron density, when h, the height of the layer is small compared with R, the earth's radius, this is approximately

$$\frac{Ne^2c^2}{\pi m} = \sin^2\theta + 2x,$$

where $x = h/R$, and where e, m, and c have their usual significance

In general, if such a frequency ν is chosen that $\frac{N_{max.}e^2c^2}{\pi m\nu^2} = \delta < 1$, then those rays for which $\sin^2\theta > \delta - 2x$ will not be returned to earth

The method, then, consists in determining the value of θ_{max}, that is, the greatest angle at which rays are reflected to earth For this purpose an accurate determination of θ is necessary The working of the facsimile device between New York and England on a wave length of 22 m has provided an opportunity of accurate measurement of these ray angles

If a single short impulse $< \frac{1}{1000}$ sec duration is sent out by the transmitter, it is generally reproduced as 2, 3, 4, or even 5 separate images corresponding to various rays of elevation at the receiving end θ_1, θ_2, θ_3, θ_4, θ_5, etc From the speed of the receiving drum it is easy to calculate the time intervals T_{1n} between these signals and using the relation

$$T_{1n} = \frac{d}{c}\left(\frac{1}{\cos\theta_n} - \frac{1}{\cos\theta_1}\right) = \frac{d}{c}\left(\frac{1}{\cos\theta_n} - 1\right),$$

where d is the distance of transmitter from receiver (assuming $\cos\theta_1 = 1$), to calculate accurately the value of θ_n

Values of θ up to 35° have been obtained and the value of θ_{max} was found to decrease throughout the night Using this material, the accompanying curve (Fig 1) representing N_{max} as a function of the time after sunset has been secured It is confirmed less accurately by transmission results which give the shortest wave that will return to earth at any given time of the night, and represents therefore the variation of N throughout the night

The dotted line represents the theoretical recombination curve $N = \frac{N_0}{1 + N_0 at}$ where t is the time after sunset The value of a, the recombination coefficient, can then be determined from the best fitting curve, and its value appears to be close to $8\ 75 \times 10^{-11}$ cm ^{3}/sec

The physical significance of this quantity can best be realised by calculating the distance to which the electron must approach a positive ion in order to be captured, that is the 'recombination radius' This depends on v the electron velocity If we assume the electrons in temperature equilibrium at 300° absolute, $v = 1\ 1 \times 10^7$ cm/sec and σ the recombination radius is $1\ 4 \times 10^{-9}$ cm If the actual value of v were v_0 and not $1\ 1 \times 10^7$, the value of a would be $1\ 4 \times 10^{-9}\sqrt{\frac{1\ 1 \times 10^7}{v_0}}$ cm, $\sigma = 1\ 4 \times 10^{-9}/\sqrt{28V}$, where V is the voltage equivalent of the electrons of velocity v This seems a reasonable value in view of the theoretical work of Kramers, Eddington, Milne, and others [1]

Unfortunately, only recombination radii for stripped nuclei can be obtained theoretically from Kramers' formulæ, namely,

$$\sigma^2 = \frac{10^{-20}}{V}\,\frac{Z^4}{r^3(9\ 5z^2/r^2 + 0\ 7V)},$$

where Z is the atomic number, V is the equivalent voltage of the recombining electron, and r the number of the quantum state in which the electron is captured No reasonable adjustment of V can make this formula agree for the ionised hydrogen atom, and the least value of Z required is 7, $r = 1$, in which case σ is $1\ 22 \times 10^{-8}$

The pressure at the measured 'equivalent height' at which the observed recombination occurs, namely, 340 km, is entirely unknown, but certain results, independent of this pressure, may be given

The mean free life of an electron between ionisation and capture is approximately five hours Assuming $v = 1\ 1 \times 10^7$, then the total distance travelled in this time is 2×10^8 km although its final distance from the origin is much less, of course, depending on the number of collisions made with other molecules

During this period it makes about 120 collisions with ionised atoms within a radius of $2\ 74 \times 10^8$ cm (the assumed average radius of the atoms of the atmo

sphere) These last figures depend on the assumed value of v

Freshwater Biological Research in the Indian Empire.

I have read with deep interest the article by Prof F E Fritsch under the title of "Research in Freshwater Biology and the Functions of a Freshwater Biological Station", published in Nature of Feb 15 (vol 125, p 241) Work in this line is imperative in the Indian Empire Algological research in the Indian Empire is still in its infancy Investigation into the algal flora of this country is not only valuable for its purely scientific interest but also from a practical point of view, as hinted in Prof Fritsch's article So far as my experience goes, this land is very rich in algal vegetation From a few bottles of algæ collected from the Loktak Lake, Manipur, Assam, by the late Dr N Annandale, Dr Bruhl[1] and I have discovered as many as forty three new species of algæ Most of them were found from a small bottle In my recent work[2] on freshwater algæ of Malayan waters, I have described four species and five new varieties which appear new to science Previous works on the algal flora of this country such as those of Turner,[3] West,[4] and N Carter[5] also confirm the prospect of a similar finding of interesting new plants and forms peculiar to the Indian soil and climate

Not much work from the point of view of periodicity, quantitative analysis or ecological study has yet been done here except Fritsch's important publication on "A General Consideration of the Sub aerial Algal Flora of Ceylon and a Contribution to the Study of Tropical Algal Ecology Part I Sub aerial Algæ and Algæ of the Inland Freshwater" Recently, however, I have taken up work on the biological investigation of the filter beds of Calcutta—in collaboration with Rai Bahadur Dr G C Chatterjee (protozoologist), Dr T K Ghose (chemist), and Mr K N Das (zoologist) The work, so far as results obtained up to now show, is of immense importance from a biological point of view as suggested by Prof Fritsch It has been observed that there is a regular rotation in the growth of algal vegetation in the filter beds, which is invariably associated with animal organisms, such as Protozoa, sponges, worms, larvæ of insects and molluscs sp Growth of green algæ predominates over the blue green ones, and diatoms are found either as pure formation or as epiphytes *Synedra affinis* var *fasciculata* is the most common species present in all the filter beds Of the algæ, *Clathrocystis aeruginosa*, *Volvox globator*, *Cladophora crispata* var *genuina*, *Zygnema* sp, *Tribonema bombycinum*, *Gloeotrichia natans*, *Hydrodictyon* sp often grow either as pure or mixed formation or by rotation, one appearing after the other These grow frequently in such huge masses that they have to be scraped off and carried away in cartloads

The life histories of these algæ are intimately connected with and thus controlled by the physical, chemical, and climatic conditions in and around the filter beds Detailed algological and chemical analyses of this water of the filter beds are being carried on, and the correlation of all the factors will, it is expected, throw much light on the aquatic biology of the filter beds Experiments for the control of the different species have been undertaken with the view of keeping the filter beds to a certain extent free from the crowded growth of algal vegetation, as the growth of the algæ sometimes reaches the point when it chokes up the action of filtration Then the masses of algal vegetation, by dislodging from the bottom, cause fissures in the floors of the filter beds which become the abode of animal organisms and thus the filter beds are rendered defective Algal contents of the oysters of the Malay Peninsula are also being investigated

There is, therefore, a vast field for research work in various avenues for the algologists in India There is no doubt that biological investigations of fresh and marine waters of this country are of greatest importance from the points of view of pisciculture and sanitation, for fish, one of the important foods for human beings, are directly or indirectly dependent on algal vegetation, and some lower members of algæ also by assimilation of organic matters for their growth expedite the self-purificatory action of the water

The Acquired Characters of *Alytes*

I am glad to see from Dr Walker's letter in Nature of April 12, p 562, that he does not dispute Kammerer's work He is fully justified in doing so since the visit of Kammerer's teacher, Prof Przibram, to London last year, because Kammerer's work was carried out under Prof Przibram's supervision and Prof Przibram, who stayed with me, assured me that the work was sound and that he himself had seen the modified *Alytes* when alive

But Dr Walker asserts that the work, if fully confirmed, would afford no proof of the inheritance of acquired characters because the modified *Alytes*, if replaced in the normal conditions, would in all probability revert to the type form This assertion implies a confusion of thought in Dr Walker's mind, which is shared apparently by many others

It is no explanation of Kammerer's results to say that they are due to "the presence in the germ plasm of potentialities to respond in a definite manner to changes in the environment" Undoubtedly this power resides not only in *Alytes*, but also in greater or less degree in all organisms—otherwise there would be no possibility of evolution The question at issue is whether the exercise of this power in one generation affects the possibility of its exercise in subsequent generations—and Kammerer's experiments not only on *Alytes* but also on *Salamandra* prove in the clearest manner that this is so Dr Walker apparently expects that if an animal, moved from environment A to environment B, responds by a change in growth and structure, this change should persist without alteration when it is moved back from environment B to environment A What we might reasonably expect, and what as a matter of fact we find, is that when the animal is kept for several generations in environment B, the response is intensified and appears earlier in development—in a word, that it becomes more *engrained* in the hereditary complex, and that when it is moved from environment B to environment A,

there is a *lag* in the re-assumption of ancestral characters.

It required, according to Kammerer, no less than six generations in the modified environment to awaken in *Alytes* the ancestral potency to produce the nuptial pad; and the offspring of *Salamandra maculosa*, which had been reared in a yellow environment, became yellower for the first eighteen months of their lives in spite of the fact that they were reared in a black environment. Similar results were obtained by Durkhen with the pupæ of white butterflies, and the cumulative effect of succeeding generations in intensifying acquired immunity has been beautifully shown by Metalnikoff in the caterpillars of the bees-wax moth *Galleria*.

In conclusion, let me describe a series of experiments carried out in my own laboratory at the Imperial College of Science under my supervision by my former colleague Dr. (now Prof.) Hogben. We had specimens of two very similar newts living in our tanks, namely, the axolotl (*Siredon pisciformis*) and the mud puppy (*Necturus lateralis*). Both normally live all their lives in water and retain external gills and open gill slits through life. Both were fed in the same way with thyroid, and the miracle of the change in a few weeks of the axolotl into a small black land newt was enacted before our eyes. But no amount of thyroid feeding made the smallest change in the appearance of the mud puppy. In one case the power to metamorphose into a land newt, though overlaid by the new perennibranchiate character, still survived as a 'suppressed complex'; in the other, owing to the deeper engraining of the perennibranchiate character, it had apparently been irretrievably lost.

Adsorption on the Crystal Lattice of Cellulose.

INVESTIGATIONS into the adsorption of various substances by cellulose in the presence of dispersive mediums such as sulphuric acid, zinc chloride solution, etc., have resulted in some very interesting observations in my laboratory during the past two years.

The more important of these will be published in due course, but meanwhile the nature of the blue, violet, and red iodine adsorptions from a solution of iodine in potassium iodide in the presence of the dispersive solutions is of considerable theoretical interest to those who are working either with cellulose or similar colloidal substances.

1. A pencil of light, passing through a natural fibre of cellulose (a flat spruce tracheid, for example), the latter being deeply stained with iodine by the methods indicated above but still translucent enough to pass light, is completely polarised by absorption.

2. Two fibres stained with iodine in this way, when crossed at right angles, behave like tourmaline plates, giving total absorption of the light at the area of crossing.

3. Microscopical analysis of this phenomenon proves that the polarisation of the light is caused by ultramicroscopic crystalline particles of iodine oriented on the crystal lattice of the cellulose either as an isomorphic or an isogonic overgrowth, or intergrowth.

4. It is presumed from the optical properties of the smallest crystals of iodine observed under the microscope that these crystalline particles of iodine are rhombic prisms.

5. The iodine penetrates into the interior of the cell walls, but the concentration is greatest on the surface, where it tends to develop into an actual microcrystalline overgrowth of iodine crystals.

In other experiments definitely oriented crystal overgrowths of calcium carbonate and barium sulphate (both rhombic) have been produced on natural fibres of cellulose. In the case of natural dendritic growths (arising from a particle of bronze or copper) in paper, the actively spreading material during the fern-like growth is copper sulphide which is also rhombic in structure.

With regard to the blue and red absorptions of iodine on cellulose, which are still under investigation, the following points may be noted:

1. It is expected that some further light will be thrown on the problem of the formation of similar coloured adsorption compounds of iodine with other substances, now a subject of considerable interest in colloidal chemistry.

2. This type of adsorption of one crystal lattice upon a second may possibly take place in the dyeing of cellulose. The iodine stained fibres, like those dyed with cotton and basic dyes, are strongly dichroic. In the latter case dichroism is the only evidence of orientation, but in the case of iodine we have both strong dichroism and complete absorption of one ray giving polarisation of transmitted light. It appears probable that the dichroism of the dyed fibres may not be due merely to the orientation of the cellulose micellæ, but also to the crystalline structure of the dye micellæ similarly oriented.

3. The iodo-sulphates of quinine (artificial tourmaline or 'herapathite') which are also strongly dichroic may be isomorphous crystalline compounds, as their peculiar optical properties are clearly due to similar properties in the iodine itself.

Atmospheric Light Columns from Artificial Lights.

WHEN travelling by tram, I have often seen the light of street lamps drawn out into beams perpendicular to the direction of streaks left upon the window glass. Effective fibres of the cleaners' cloth are sensibly parallel, and though I had mentally noted that the beams were due to diffraction, it had not hitherto seemed worth while publishing the observation. I would suggest, however, that it provides a simple analogue for the atmospheric light columns mentioned by Dr. Currie in NATURE of April 5.

There can be no doubt that the vertical atmospheric beams are due to horizontal particles, which need not be laminar as suggested by Dr. Whipple. Some readers may find difficulty in accepting a horizontal orientation of falling particles, and it is therefore of interest to recall the observations of Dr. John S. Owens (*Brit. Assoc. Rep.*, p. 611, 1913) upon the deposition of silt and sand in water. He found that when bodies of different shape (discs, rectangular plates, or rods) were allowed to settle in water, they settled in every case in the position offering the greatest resistance to movement.

Construction of a model to produce light columns presents no difficulty in principle; all that is required is a suspension of lamellar or acicular particles within a transparent chamber having plane parallel sides. I believe I have obtained an indication of the effect with crude apparatus, but a successful result could be obtained only under rigorous conditions in which the effects of convection and tremor can be eliminated.

The apparently contradictory orientation of both lamellar and acicular particles when suspended in a fluid at rest, and when giving rise to the phenomenon

which I called '*swirl opalescence*' (NATURE, 123, 491, 1929) are consistent with the principle of least action I should like to mention that I accept Dr A S C Lawrence's suggestion (private communication) of the term '*stream scintillation*' in place of swirl opalescence HUGH NICOL

The New Planet

DANS le numéro de NATURE du 12 avril, p 577, le rédacteur de la note "The New Planet" suppose gratuitement que j'ai commis une erreur de raisonnement dans le calcul du diamètre photométrique de la nouvelle planète L'inexactitude de cette supposition se trouve démontrée par ma Note, présentée à l'Académie des Sciences de Paris dans sa séance du lundi 7 avril, intitulée "Sur le calcul du diamètre photométrique du corps céleste de l'Observatoire Lowell" (*Comptes rendus*, t 190, p 857, 1930), où se trouve précisément reproduite la formule qui m'a servi

$$\log \frac{D}{D'} = \frac{1}{5}(m' - m) - \log \frac{r'\Delta'}{r\Delta},$$

et aussi par ce fait que le calcul basé sur le carré de la distance r' au lieu du carré du produit $r'\Delta'$, ne donnerait pas 1500 km avec les constantes que j'ai indiquées ($D = 53{,}000$ km, $m' = 15\ 0$, $m = 7\ 5$, $r' = \Delta' = 45$, $r = 30$, $\Delta = 29$, $A = 0\ 6$, $A' = 0\ 15$) mais 5000 km En réalité, il s'était glissé dans *l'Information Rapide*, et ma première Note à l'Académie qui en est la reproduction, une simple erreur numérique dont j'ai publié aussitôt une rectification F BALDET

Observatoire de Meudon,
Avril 12

ALL that was stated positively in the note on M Baldet's diameter of the new planet was that his conclusion that its diameter was only 1500 km if its albedo was taken as 0 15 was erroneous His present note is in full accord with that statement, since he now gives, in *Comptes rendus* for April 7, a diameter of 2500 km, taking the albedo equal to that of Neptune, that would give 5000 km with an albedo ¼ that of Neptune

The note in NATURE went on to say (correctly) that some people had made the mistake of making the light vary as the inverse square of the distance, instead of the inverse fourth power M Baldet's letter makes it quite clear that he did not fall into this error Needless to say, the note was written and published before any correction of M Baldet's original statement had been received

THE WRITER OF THE NOTE

Influence of Chemical Colloidisation on the Anomalous Diamagnetism of Bismuth and Antimony

IT is a well known fact that antimony and bismuth possess a high diamagnetism in the solid massive state, the specific susceptibilities being $0\ 78 \times 10^{-6}$ and $1\ 17 \times 10^{-6}$ respectively at 30° C according to my experiments In a communication published in NATURE of Nov 16, 1929, p 762, I reported the results of the influence of particle size on the anomalous diamagnetism of antimony, its value falling on mechanical colloidalisation Further experiments on chemical colloids of bismuth and antimony show a still more striking decrease

Colloidal antimony was prepared by reducing a solution of potassium antimonate by sodium hydrosulphide This was centrifuged and the fine particles further purified in very dilute hydrochloric acid and carbon disulphide to remove traces of iron and sulphur The specific diamagnetic susceptibility obtained was $0\ 31 \times 10^{-6}$ with a particle size of about 100 $\mu\mu$, the particles themselves appearing as clusters of small particles

In the case of bismuth, the colloid was prepared by reducing bismuth tartrate by stannous chloride in alkaline lye and centrifuging The purified substance gave a diamagnetic susceptibility of $0\ 25 \times 10^{-6}$ (See also Honda and Owen, *Ann der Phys*, 37, 657, 1919, where Kahlbaum's colloidal bismuth is reported to give $0\ 47 \times 10^{-6}$, whereas in the massive state it is $1\ 4 \times 10^{-6}$)

These results seem to indicate that the high diamagnetism of these elements and that of graphite (Sir C V Raman, see NATURE, June 22, 1929, p 945) is a crystalline property and not atomic as diamagnetism is generally understood to be

Leaf-Curl in Cotton

IN an article entitled 'Cotton in Africa" (NATURE, Feb 22, 1930, pp 291 292), referring to cotton in the Sudan, it is stated that 'Recently the disease known as leaf curl has been attacking the crops in this locality, and there is evidence that the jassid insect is responsible for spreading the contagion The Corporation is now considering the desirability of breeding jassid resistant strains in the Sudan"

Working in the Gezira area, which is by far the most important long staple cotton producing locality in the Sudan, I have recently proved that leaf curl of cotton (or, as it should preferably be called, leaf crinkle) is transmitted mainly, if not entirely, by an at present undetermined species of Aleurodidæ (White-flies) A preliminary paper on the subject has been submitted for publication

Mounting Media for Microscopic Work

ALTHOUGH, as Mr Wilfrid Marshall points out in NATURE of April 12, there appears to be no theoretical advantage in using a mountant containing dried Canada balsam and α bromonaphthalene, in practice the mixture has the valuable property of high viscosity The use of a medium of high viscosity enables fresh mounts to be photomicrographed at high magnification, using the microscope in a horizontal position, in fact, we now find it to be an advantage to use twice the stipulated quantity of dried Canada balsam in order to make the mountant as viscous as possible, so that film sections may be photomicrographed within a few minutes of being cut E E JELLEY

Some Solar Eclipse Expeditions of 1930 and 1932

By Prof F J M STRATTON

THE two total solar eclipses of this year are not attracting organised expeditions from Great Britain The first one, on April 28, was annular over most of its path, though it was total along a narrow belt not more than half a mile wide from just north of San Francisco across Nevada and Idaho to a point north of Virginia City in Montana The uncertainty in the position of the belt was estimated at a quarter of a mile, and totality was nowhere longer than 1 5 sec An eclipse of this kind may be valuable for the investigation of the flash spectrum at different levels, and observing parties went not only from the nearby observatories of Mt Hamilton and Mt Wilson, but also from the Allegheny Observatory It is to be hoped that answers have been obtained to some of the problems which, with the aid of clouds, have been eluding eclipse observers for the past few years

The second total eclipse of this year, that of

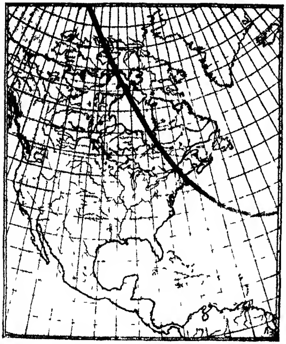

FIG 1

Oct 21-22, is visible from the small island of Niuafou in the Tonga Islands and near sunset in Chile and Patagonia Totality lasts 2 minutes The New Zealand government and the United States Naval Observatory are sending expeditions to Niuafou. A recent volcanic outburst which partially destroyed the island will add to the difficulties which must face these parties in arranging their eclipse camps, but may also appreciably add to the interest of the expeditions Dr C E Adams is going as leader of the New Zealand expedition and Prof S A Mitchell as leader of the American party

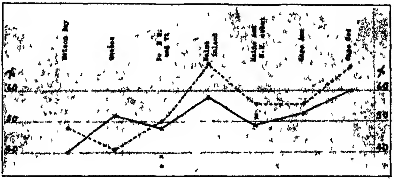

FIG 2

The next eclipse which is likely to be widely observed is that of Aug 31, 1932, visible in Canada and in the Eastern United States (Fig 1) The next ordinary General Assembly of the International Astronomical Union will be held about a week later at some nearby centre in the United States, so that a number of astronomers from other continents may be expected to observe this eclipse alongside of their Canadian and American colleagues

Five years ago Prof Todd began collecting weather observations along the track of this eclipse, and in 1929 Prof Slocum took over from him the task of collecting and collating the data He has published the results of the observations to date in *Popular Astronomy* for April, and with his permission some of his data are reproduced here As will be seen from Fig 2, the chances of success are about one half at most stations between Hudson Bay and the coast of Maine Only the intermediate stations are considered by Prof Slocum, who suggests that the best place for a camp is some distance back from the Maine coast, perhaps between East Baldwin and Fryeburg

South of the St Lawrence River in Canada, as also in the States, the central line is readily accessible by rail, and it should be easy to spread a number of observing parties along the central line At Yamachiche, on the St Lawrence River, there is a large Marconi wireless station At Drummondville, Sherbrooke, and Magog good accommodation would be available, but there should be none of the difficulties that frequently await eclipse expeditions in out of the way parts of the world, and a well distributed set of parties may hope to secure a reasonable proportion of successful observations

It should be added that totality lasts about 100 seconds, that the width of the belt of totality is about 80 miles, and that its south western edge runs from Montreal to the coast of Massachusetts midway between Salem and Gloucester

Problems of Irrigation

By Prof B H WILSDON

THE introduction of irrigation in an arid country, along with its obvious blessings, brings in its train diverse problems, as do most other of man's disturbances of Nature's equilibrium The consequences may give rise to problems of such urgency that, unless solved, large tracts of land, after a period of fertility productive of an ever increasing density of population, must lapse into saline desert or into waterlogged marsh infested with malaria Difficulties will be at their worst in flat country devoid of drainage

Terrain, soil and sub-soil, climate, the design of irrigation channels, the method of distribution of water, and the habits of the cultivator, must all be factors which contribute to the permanent success or ultimate disaster of irrigation projects Only by the systematic study of their interactions can it be hoped to secure control of effects Control is perhaps too strong a word to use when the complex reactions which follow the apparently simple engineering feat of digging a canal for irrigation are properly considered, but for the possibility of disaster we have object lessons in the ruined irrigation systems of Mesopotamia and the Punjab, which must once have supported flourishing civilisations

In the Punjab an average flow throughout the year of about 25,000 cubic feet of water a second is maintained by irrigation works by which some 10½ million acres of crops are matured in land previously desert or precariously cultivated These figures omit the great areas which are now coming into cultivation as a result of the new irrigation works on the Sutlej, and greater areas, which will be irrigable when the Sukkur barrage on the Indus is completed

Of the 10½ million acres irrigated in the Punjab, the area threatened with waterlogging has been estimated at 3¾ million acres [1]

The new areas now being brought under irrigation are probably more liable to damage than those in the Punjab, since, in general, soils become heavier and the fall of the land flatter as we proceed south

The need for research has been recognised, but not too soon As a matter of Imperial interest, the question has been under examination for some time by a special committee appointed by the Committee for Civil Research The report of this body will be awaited with interest In the Punjab, the ominous rise of the water table in many irrigated tracts, the abandonment of an increasing acreage of once fertile land through actual waterlogging and the spread of saline soil, could not be longer ignored Some preliminary steps have already been taken in an attack by scientific methods upon the analysis of the factors, and in attempts at control, by the formation in the Punjab under the Irrigation Department of a research organisation A laboratory equipped for the study of the hydrodynamic and physico-chemical problems which await solution is nearing completion, and a staff of computers for statistical investigations has been at work for some time Already some light has been thrown on the gravity of the problem, and indications of the most feasible methods of control by administrative methods or engineering works have been secured A brief account of the results obtained and the problems now more clearly defined may, it is hoped, reveal subjects of scientific interest to workers in many fields whose active interest would be of valuable assistance to those called upon to face the situation

Fortunately, due to the foresight of a former chief engineer of the Punjab—Sir Thomas Higham—extensive records have been kept for nearly thirty years of the depth of the water-table in selected wells scattered more or less uniformly throughout the irrigated tracts This valuable collection of data, with records of rainfall maintained by the Irrigation Department at sub-divisional stations, and the recorded volume of irrigation water admitted to canal distributaries, enables statistical estimates to be made, not only of the present and future rate of rise of a water-table but also of the relative responsibility of rainfall, drainage, and the irrigation load for the effects observed [2]

The method of analysis adopted has been that developed by R A Fisher [3] of the Statistical Department of Rothamsted Experimental Station in the examination of the relation between rainfall distribution during the growth of a crop and its yield This method was necessary, as there is every reason to expect that rainfall or irrigation in excess of the normal will not have the same effect on the water table at different seasons of the year since the quantity of water lost by evaporation, and able to affect the water table, must depend intimately on the prevailing temperature and humidity Moreover, well measurements have only been recorded on two dates in the year, in June and October, and the latter are not very trustworthy on account of the after effects of flooding due to the previous monsoon The method adopted was therefore to correlate the constants determining a polynomial curve fitted to the distribution of rainfall and irrigation in the year previous to the well observations, with the fluctuations of the spring levels after correction for secular trend Typical regression curves are reproduced in Fig 1 The ordinates represent the effect in the following June of unit departures from the average depth of irrigation on the rise of the water-table

Such curves represent the result of heavy computations More than three hundred individual well records are included, each of which is suitably weighted for the area of which it is taken as representative Secular change was eliminated from the record of well fluctuations by fitting an exponential curve, departures from which were

correlated with the rainfall and irrigation distribution

The available record varies from 20 to 27 years in the cases examined The unit of time was taken as five days, for each of which it was necessary to compute the rainfall from about fifty rain gauge stations and the records of many canal distributaries The correlations are undoubtedly significant according to statistical criteria, the percentage of the total variance accounted for by the regression being more than 60 per cent in the mean for the cases illustrated

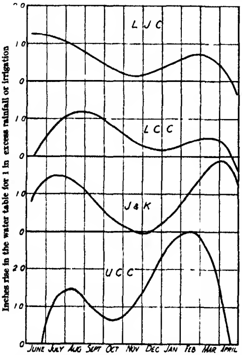

FIG 1 —Typical regression curves showing the effect of rainfall or irrigation on the rate of rise of the water table

L J C —Lower Jhelum Canal Area, 2096 sq miles recorded wells 80, perennial irrigation

L C C —Lower Chenab Canal (Upper) 2030 sq miles, recorded wells, 54, perennial irrigation

J & K —Jaurian and Kasoki distributaries Area 65 2 sq miles, recorded wells 6, the water table is high and a considerable proportion is irrigated by wells

U C C —Upper Chenab Canal Area, 2486 sq miles, recorded wells 83 the water table is high throughout the area and a large proportion receives irrigation only in the summer season A large area of rice is grown

There is a marked uniformity in the regressions for the monsoon period, July to September Roughly we see that a depth of water added to the surface of the soil as irrigation or rain produces an effect on the water table, detectable six months afterwards, of from one to one and a half times its amount This indicates that from one third to one half of the water must reach the water table from the surface, since the porosity of the soil may be assumed to lie between 30 and 40 per cent The effects of irrigation during the winter months are more diverse, as might be expected There is, in addition to the monsoon maximum, an obvious tendency to attain another maximum effect during February and March This is most marked in the Upper Chenab Canal, which differs very considerably in its agricultural regime from the others

The winter 'hump' in the regression curve has afforded an instructive insight into agricultural practice, and has been traced very conclusively to wasteful irrigation The most important application of the results has been in guiding administrative action in insistence on economy It is obvious from the curves that great effects are possible through economy, or avoidance of waste, during the monsoon, and, on certain canals, during February and March The total closing of certain canals for periods during the monsoon has been tried and would already seem to have produced promising results without undue interference with agriculture The effects in future years of the policy now adopted will be awaited with great interest

Fig 2 shows the mean observed annual rates of rise of the water table, averaged from 54 separate well records over a tract of about 2500 square miles in the Lower Chenab Canal The exponential correction for trend is also shown, as well as the fluctuations calculated by means of the derived regression equation from the recorded irrigation and rainfall The fit of the observed and calculated fluctuations in the rate of rise is remarkable

If we assume that the rise of the water table, falling off exponentially as it appears to do, will continue unchecked, it is calculated that the water-table as a whole will rise another 13 feet above its level in 1927 This must result in a very considerable portion of the area becoming water-logged By a similar calculation for the Lower Jhelum Canal, in which the water table has exhibited a remarkable rate of rise, the corresponding final equilibrium is calculated to be 56 feet above its present level

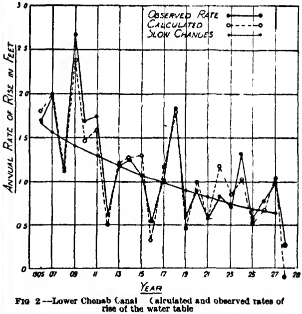

FIG 2 —Lower Chenab Canal Calculated and observed rates of rise of the water table

A second line of investigation, on which work is

still in progress, has been directed to the elucidation of the causes for such exceptionally rapid rises of the water-table as have been recorded in the Lower Jhelum Canal since the introduction of irrigation Much of the area is easily commanded by inundation canals, but the higher areas are served by high level channels from the head works at Rasul and Mangla Tradition states that the tract was once irrigated even in the higher areas, but that "God became angry" and the land waterlogged The existence in high areas of abandoned wells which show signs of use, the curbs of which lie at levels still many feet above the present water table, confirms this tradition The map (Fig 3) shows the Rivers Chenab and Jhelum At Kirana, near the district headquarters of Sargodha, occurs an outcrop of Pre Cambrian rocks associated with the Delhi and Aravalli series Similar rocks are found at Chiniot where the Chenab passes through a gorge, and at Shahkot and Sangla farther south To the north west lies the Salt Range where rocks ranging from Tertiaries to Lower Carboniferous lie unconformably over the Aravalli Cambrians It is a remarkable fact that the principal incidence of waterlogging and the areas in which the rise of the water table has been most rapid, lie to the north-east of a line roughly joining these outcrops with the Delhi ridge This suggests the possibility that the deep Indo Gangetic alluvium is traversed by a submerged ridge along this line which might act as a weir to head up the subsoil drainage Such a rock mass would account for the sensitivity of the water table upstream.

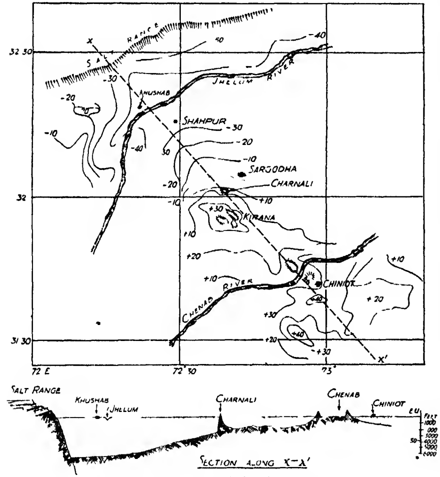

Fig 3 —Gravity survey in the Chenab Jhelum doab

It was thought worth while to substantiate this hypothesis by a gravity survey A survey party has now been in the field for three successive cold seasons, using an Eotvos torsion balance The work, which has been carried out in the field by Dr N K Bose, is not yet completed, but detailed results of the first two seasons' work will be published shortly Fig 3 shows a rough reproduction of the isogams with the omission of all detail, a section along the line X – X' is also shown Observations have been made at more than two hundred stations in the area The greatest depth of the alluvium is calculated to be about 5000 feet No other determinations of the depth of the Indo Gangetic alluvium are available for comparison, rock has never been reached by boring in the alluvium proper Extension of the results now obtained would probably be secured, at considerably less trouble than is entailed in work with the torsion balance, by the recently developed methods of seismic sounding It is to be hoped that this will prove possible in the future

It is clear that the comparatively shallow sub soils found to the south east of the tract illustrated must affect considerably its drainage, but no quantitative estimate is yet possible The rapid rise of the subsoil rock at the base of the Salt Range is a subject of considerable geological interest, but no stratigraphical conclusions as regards the type of the unconformity should be based on Fig 3

Other problems associated with irrigation must be mentioned only cursorily Satisfactory hydrodynamic theories on which may be based equations for the flow of water in a deep soil are still to be sought Even the comparatively simple case of the discharge of a tube well in a deep soil, unprovided with the conveniently situated impervious layer

always found in theoretical descriptions, is open to obvious objections The most illuminating model of such cases appears to be that of surface disturbances in an infinitely deep and highly viscous fluid This analogy has been studied mathematically by Bose [4]

The design of channels is determined primarily by the amount of silt which they must carry and discharge on the irrigated fields if the system is to remain working The transport of silt by water in turbulent flow, both as it affects the intake from the river at the headworks, and the regime of the canal, still awaits scientific description With the problems which arise in the design of irrigation works, in which model experiments, under properly adjusted conditions of dynamical similarity, alone enable three dimensional problems to be solved, enough will have been said to indicate the scope awaiting the application of mathematical and physical research

A word may be added on the agricultural problems which are inseparable from questions of irrigation Excessive irrigation and its evil effects have been mentioned, and may be regarded as a Scylla, between which and the Charybdis of the development of salinity, a safe course must be steered With sparse rainfall the salts carried in irrigation water may accumulate in the soil, so that a too parsimonious economy of water, or reversion to well irrigation without adequate replenishment of the water table with fresh water, must result in a continuously increasing salinity of soil and ground water It would appear that the only permanent solutions which can be looked for in the flat alluvial plains now considered, will be a combination of irrigation and drainage, in fact, it would be safe to state that any modern system of irrigation in alluvial plains must be designed at the outset with full provision for adequate drainage

Very much therefore remains to be done in designing effective remedies for existing systems and in the physical and chemical questions of reconditioning damaged soils

Obituary

SIR GEORGE WATT, C I E

THE death of Sir George Watt removes a figure who did valuable work for India, from which he retired nearly a quarter of a century ago He will be always remembered for his 'Dictionary of the Economic Products of India" Few would dispute the very great value on Indian economic development which has resulted from this publication

Watt was born at Old Meldrum in Aberdeenshire in April 1851, the third son of John Watt He married in 1873 Jane, elder daughter of Robert Simmie, who was Customs and Excise Officer at Lossiemouth A son, Dr R H Watt, and two daughters survive him Watt was educated at the Grammar School and Marischal College, Aberdeen, and then went to the University of Glasgow in 1871, graduating M B and C M He had obtained distinction in botany, and this led to his appointment in 1872 as professor of botany in the University of Calcutta, a post he held for twelve years In 1882 he was appointed scientific and medical officer on the Burma Manipur Boundary Commission His work and enthusiasm were beginning to attract the notice of the Government of India, and in 1883 Watt was appointed to the charge of the Indian Section of the great International Exhibition held in Calcutta in that year The following year he received the definite appointment of assistant secretary for scientific purposes to the Revenue and Agricultural Department of the Government of India In 1885 he went home and held charge of the Imperial Indian Economic Court of the Indian and Colonial Exhibition, an exhibition which fired the imagination of the public school youth of the day

By this time Watt appears to have convinced himself of the grave existing need for a better knowledge of, and comprehension of, the value of the enormous number of what, *faute de mieux*, were termed the economic products of the country He was able to impress the Government of India with his views, and in 1887 was appointed Reporter on Economic Products to the Government, a new post It has been said that Watt had been turning his attention to this question of the economic products of the country and he had commenced in 1885 collecting material for the compilation of a dictionary on the subject With his official apointment he was able to take up this project seriously and by 1894 the nine fine volumes of the "Dictionary" were completed The work was a standard one and, unfortunately, owing to the unexpected demand, went out of print at an early date

When Watt compiled the 'Dictionary" there was no Agricultural Department to the Government of India, no Pusa and no Forest Research Institute at Dehra Dun Watt's project was invaluable but, with no idea of belittling his magnificent work, it should be stated that the "Dictionary would never have seen the light of day had it not been for the loyal, intelligent, and enthusiastic assistance accorded to him by collectors and deputy commissioners of districts and their staffs, and by the forest officers throughout the country and the latter, owing to their training in scientific method and deduction, were perhaps in a better position to submit reports in a readily utilisable form Many, if not most, of the inquiries originated with Watt, and circulars were issued asking for co operation in instituting investigations and often in carrying them to a conclusion, where practicable, out in the districts There is little doubt that Watt's initiative in this respect aroused the interest of many junior officers in this matter of economic products

I had not been three months in India before a conundrum in one of the circulars was given me to deal with, and several most interesting months were passed in endeavouring to submit a satisfactory solution

The "Dictionary" was not intended as a text book or handy handbook, but it was a first definite departure in the study of the economic products and served as the basis for the great development of this study which has since come about Watt retired in 1906, but the post of Reporter was not finally abolished until both the Pusa and Dehra Dun Institutes were firmly established Watt's ledger files, which he had maintained over a long period of years, were then made over to these latter He had also edited an invaluable publication known as the *Agricultural Ledger* from 1892 to 1903, which was continued by his successors He was also in charge of the industrial section of the Indian Museum at Calcutta

It was during Lord Curzon's Viceroyalty, to some extent due to the fact that the "Dictionary" was out of print, that Watt was asked to prepare, with the guidance of a small expert committee in London, an abridged edition of the "Dictionary", to be brought up to-date and to be issued in one volume This work, under the title of "The Commercial Products of India", was published in 1908

Watt was president of the Pharmacological Section of the Indian Medical Congress in 1894 In 1901 he was appointed to the Indigenous Drugs Committee, and as secretary drafted the report In 1903 he organised an Indian Art Exhibition in connexion with Lord Curzon's Delhi Durbar

After his retirement from India, Watt made a special study of cacao cultivation, visiting Portuguese West Africa for the purpose in 1912, and patented machinery for cacao manufacture He served for five years as lecturer in the botany of Indian trees at the University of Edinburgh He was made C I E in 1886 and was knighted in 1903, he was LL D of both his old Universities, Aberdeen and Glasgow, a fellow of the Linnean Society, and had received distinctions from a number of foreign universities and scientific societies

In addition to the "Dictionary", Watt published "Pests and Blights of the Tea Plant", "Rhia and China Grass", "Lac and Lac Industries of India", and an important work on the "Wild and Cultivated Cotton Plants of the World"

Watt had settled at Lockerbie in 1910 and identified himself closely with local affairs, serving on the Dumfriesshire County Council and Education Authority His death on April 2 will be much felt by many, and not least by the band of men who were identified, one way or other, with his valuable Indian work

E P STEBBING

PROF I P BORODIN

PROF IVAN PARTHENIEVITCH BORODIN, whose death at Moscow was recently announced, was a botanist and forester of international reputation Born at Novgorod in 1847, he was educated at the University of St Petersburg, where he became professor of botany in 1887, a position he held for three years He then became professor at the St Petersburg Forest Institute, where he continued for thirty years This was formerly the largest and probably the best equipped forestry school in Europe, and many foreign students were attracted to it by the prestige of Borodin and the scientific staff In 1897 he founded the biological fresh water station which bears his name and of which he was director

Borodin's first researches were on the effect of light on the higher cryptogams, and he also worked on respiration An early paper, however, on botanical progress during 1877–79, indicated the catholicity of his interests shown later by his publications on mycology, anatomy, reproduction, and biochemistry He also wrote standard books on botany and agriculture

The study of botany in Russia owes much to Borodin's zeal and versatility, and this is shown by the numerous honours conferred upon him He was of strong physique and enormous energy, attributes which served him in good stead in the arduous botanical travels he undertook in the remoter parts of Siberia and the Caucasus His interest in travel continued to the end, and he served as president of the standing commission for the development and exploitation of tropical countries He held several other positions to which the term honorary is usually applied, but Borodin devoted himself to his duties with intense earnestness and clear thinking enthusiasm He was a man with many friends in his own and in other countries

PROF HERMAN VON IHERING

PROF HERMAN VON IHERING, who died at Budingen in Oberhessen on Feb 24 in his eightieth year, is well known from his contributions to the biology and palæontology of South America, where he was for many years Director of the Museum at São Paolo, Brazil

Von Ihering was especially interested in zoogeography and in order to test its problems by various groups of animals, specialised on land and freshwater mollusca and on the social insects, especially the wasps He had also a good knowledge of the South American mammals, recent and fossil He also wrote on the Antarctic faunas, the German Selachians, and the fossil and living mollusca of South America He was a man of original and independent views and was often engaged in controversy, on one occasion with Ray Lankester He was a pioneer in the application of parasites to zoogeography and it is often called "the von Ihering method"

Von Ihering wrote many memoirs on the anatomy and classification of the land mollusca and on the biological relations of South America His last general work was his "Die Geschichte der Atlantischen Ozeans" (June 1927), wherein he summarised and restated his former conclusions, and advocated fundamental changes in both Atlantic and Pacific geography up to the middle of the Kainozoic era

After his return from South America, von Ihering was honorary professor of palæontology in the University of Giessen Many of his views were rejected when first advanced, but are now receiving wider recognition and acceptance

---

PRINCIPAL J YULE MACKAY

JOHN YULE MACKAY, whose death on Mar 30 we regret to record, was a distinguished student of the University of Glasgow After graduation in medicine in 1882, he became Cleland's senior demonstrator and lecturer on embryology

Mackay was successful as a teacher, and, in addition, he produced original work of permanent value He devoted his attention mainly to the vascular system, and wrote a monograph on the morphology of the arterial arches in birds which was published in 1888 in the *Transactions of the Royal Society* He was with Cleland the originator of the ' Memoirs and Memoranda in Anatomy " which was issued from the Glasgow School, and its first volume, published in 1889, contained an interesting paper by him on ' The Arterial System of Vertebrates Morphologically Considered ", in which from his comparative observations, he constructed a scheme of the classification of the branches of the aorta, the correctness of which has been confirmed by subsequent embryological observations His ability and energy were shown also in the volume on Human Anatomy General and Descriptive ", which he produced in association with Cleland

Shortly after Mackay's appointment to the chair of anatomy in University College, Dundee, he was selected to be the principal of that College, and he held the dual posts until a few years ago, when he resigned the chair but retained the principalship He was for many years the University representative of the University of St Andrews on the General Medical Council, and until recently was the chairman of the Education Committee of the Council

D W

WE regret to announce the following deaths

Dr J H Appleton, emeritus professor of chemistry at Brown University, known for his work in industrial chemistry, on Feb 18, aged eighty six years

Dr Asaph Hall, of the U S Naval Observatory, vice-president in 1900 of Section A of the American Association for the Advancement of Science, who was known for his work on the orbits of planetary satellites, on Jan 12, aged seventy years

Prof Conrad Keller professor of special zoology in the Technical Highschool, Zurich, author of works on the origin of domestic animals, aged eighty two years

Dr W A Orton, director of the Tropical Plant Research Foundation, formerly plant pathologist in the U S Department of Agriculture, and president in 1921 of the American Phytopathological Society, on Jan 7, aged fifty two years

Dr R F Ruttan, emeritus dean of the faculty of graduate studies and research at McGill University, past president of the Royal Society of Canada and of the Society of Chemical Industry, on Feb 19, aged seventy three years

Prof L Vialleton, honorary doyen of the faculty of medicine of the University of Montpellier author of works on histology, evolution, and other zoological topics, aged sixty nine years

News and Views

ON May 10 occurs the centenary of the birth of the distinguished French chemist, François Marie Raoult The son of a customs officer, he was educated at Laon and Paris, became a teacher, held various appointments at Rheims and elsewhere, and in 1870, at the age of forty, succeeded to the chair of chemistry at Grenoble, where the remainder of his life was passed His earliest researches were largely connected with the phenomena of the voltaic cell, but his name is best known for his work on solutions, which occupied the last two decades of his life His first paper on the depression of the freezing points of liquids by the presence of substances dissolved in them was published in 1878 Continued experiments with various solvents led him to the discovery of a simple relation between the molecular weights of substances and the freezing point of the solvent which he expressed in the " loi générale de la congélation " He also studied the diminution of the vapour pressure of a solvent caused by dissolving a substance in it, and his important work in these directions was afterwards used by such eminent investigators as van 't Hoff and Ostwald in support of the hypothesis of electrolytic dissociation in solutions An account of his work was given in a memorial lecture in 1902 by van 't Hoff before the Chemical Society, of which Raoult had been elected a foreign member in 1898 A modest, retiring, and dignified man, he lived mainly for his work, the value of which was recognised by the award of prizes by the Paris Academy of Sciences and of the Davy Medal of the Royal Society His death took place on April 1 1901

FOR the public Kew is a delightful pleasaunce for the gardener a demonstration of achievement and a suggestion of possiblities, and for the botanist a store house of information and a centre for research The recently issued number of the *Bulletin of Miscellaneous Information* (Appendix I, 1930), comprises under this familiar but somewhat unattractive title, a review of the work of the various departments of the Royal Gardens during 1929 In 1925 work was begun on the formation of a National Pinetum at Bedgebury, in Kent, as the nearness of London is not conducive to the growth of conifers, and in spite of the long cold winter and abnormally dry summer of 1929, good progress is reported The abolition of the penny charge for admission to the gardens from August Bank Holiday onwards is reflected in an increase in the number of visitors of nearly 220,000 between August and December, as compared with the corresponding period in 1928 The hard winter of 1928–29 and the boisterous gales of the last two months of the year caused severe losses among shrubs and large trees, but the long hot summer gave an unusual brilliance of colour to the abundant crops of fruits and berries on

many of the trees, and the later incessant and heavy rains effectively cleansed trees and shrubs from soot and dirt

THE more strictly botanical activities of the Royal Botanic Gardens, Kew, have benefited by generous grants from the Empire Marketing Board, which have rendered possible visits by the scientific staff and various collectors to different parts of the Empire overseas and elsewhere, resulting in valuable accessions to the gardens and herbarium, and the gain of invaluable experience to individual members of the staff Mr Hutchinson's botanical tour in South Africa produced a harvest of more than 3000 species, including a large number of living succulent plants Work of botanical exploration has also been carried out in British Guiana, Persia, Somaliland, and the Solomon Islands Considerable additions have been made to the herbarium, mainly by the incorporation of stored material An important feature of the work is the international co operation in research rendered possible by an extension of the system of reciprocal loans between important botanical institutions, during the year more than 9000 specimens were borrowed and nearly 6000 sent out on loan Botanical work in South Africa will be greatly facilitated by an arrangement to present to the National Herbarium at Pretoria duplicates of authentic specimens in the Kew Herbarium The report of the museums records an increasing interest taken in the economic products of plants, involving much correspondence and discussion of home and colonial products with visitors The difficulty in answering questions as to possibilities of new crops for home or the colonies is often enhanced by the lack of discretion on the part of optimistic journalists An interesting acquisition is a new sun dial constructed and presented by Prof C V Boys, which was described in NATURE of Dec 21, 1929

WE have received a letter from Prof G E Gates, of Judson College, Rangoon, in which he directs attention to the loose way in which authors of zoological papers still frequently refer to species of earthworms, even when these actually supply the material of their investigation Thus a recent writer speaks of "the common Australian (European) earthworm", the question is, What is meant? Presumably, says Prof Gates, one of the peregrine Lumbricida that have been imported into Australia and have become acclimatised in settled areas around the cities But "at least six species of Lumbricids have been recorded from Australia *Eiseniella tetraedra*, *Eisenia fœtida*, *Allolobophora caliginosa*, *Bimastus constrictus*, and *Octolasium lacteum* These worms when found elsewhere are usually present in considerable numbers, so that to each one of them the adjective 'common' might be applied Thus an investigator who procures his earthworms from manure piles might regard *E fœtida* as the common species, while another investigator who gets his material from the very same locality but at a distance of a very few feet from the manure piles would probably find another species to be the common form Similarly a thick grove or river bank only a short distance from both the preceding places might have still other common species The phrase 'the common earthworm' in such a region must therefore be nearly as meaningless as 'the common bird' or 'the common fish' would be" Even though one of these species should happen to preponderate so largely in one particular place as to deserve the name, locally, of 'the common earthworm', outsiders cannot be expected to know which is meant The importance of the matter, as Prof Gates points out, lies in the fact that in such cases corroboration of the results obtained is impossible, and their value, therefore, very considerably diminished, because of the anonymity in which the animal concerned is shrouded It is not only the Oligochæta which are thus cavalierly treated by authors, in the same paper which calls forth these remarks, the monocystid parasites with which the writer is concerned are also left specifically undetermined

THE issue of the *Times* for April 26 contains a letter from Sir John Rose Bradford, president of the Royal College of Physicians, in his capacity of Chairman of the Harvey Church Memorial Fund, appealing for funds for the restoration of the tower of Hempstead Church, Essex, the resting place of William Harvey, which collapsed in 1882 An appeal was made in the *Times* last January not only to individual practitioners of medicine, but also to medical corporations, institutions, societies, and schools, with the result that some £1500 of the £5700 required has been raised The present appeal is primarily directed to members of the medical profession, by whom Harvey is generally regarded as second only to Hippocrates, but it is hoped that it will provoke a generous response from laymen as well, particularly those who can appreciate Harvey's exhortation to the fellows of the Royal College of Physicians 'to search and study out the secrets of nature by way of experiments' The present dilapidated condition of Hempstead Church has not infrequently created an unfavourable impression upon the foreign medical men who have made a pilgrimage to Harvey's tomb A new importance is now assumed by the erection of a worthy memorial to Harvey at a time when, as we noted in our issue of April 19, a special effort is being made to establish a post graduate school of medicine in London and to attract foreign students to Great Britain Donations should be made payable to the Harvey Memorial Fund, and may be sent to the honorary treasurer, Mr A W Ruggles Brise, Spain's Hall, Braintree, or to Dr Arnold Stott, 58 Harley Street, W 1, who is joint honorary secretary with the Vicar of Hempstead

AN interesting tradition has long been current that Comenius (Jan Amos Komensky) the famous seventeenth century pedagogue, was invited to accept the presidency of Harvard College, founded in 1636 The evidence that such an offer was made by the younger John Winthrop (1606–76), Governor of Connecticut, rests upon the authority of two references to it by Cotton Mather, of Boston, in works published in 1702 and 1726 Recently, Mr R FitzGibbon Young has re examined the evidence

("Comenius and the Indians of New England", pp 28 University of London School of Slavonic Studies Price 3s net) and, by taking into consideration the circumstances of time and place, has concluded that whilst there is definite evidence that Comenius was invited to New England, the presidency of Harvard was not vacant when Winthrop could have seen him Nevertheless, his pan sophic educational schemes received the careful consideration of contemporary American educationists Mr Young has also traced Comenius's connexions with Robert Boyle, Dr Wilkins, Sir Kenelm Digby, and other members of the "invisible college" which was later to become the Royal Society It would seem that the intention of certain savants, both in England and America, was that Comenius's methods of instruction should be applied to the unsuccessful attempt then set on foot for educating the American Red Indians upon the most advanced western European lines Nothing came of the project, but Comenius's views can still be regarded as of some historical interest

FOLLOWING the decisions at Dusseldorf in 1910, the sixth session of the International Congress of Mining, Metallurgy, and Applied Geology will be held at Liège on June 22–28 next during the International Exhibition of 1930 These meetings will be under the gracious patronage of His Majesty King Albert and of the Belgian Government The Congress has been organised by the Liège Association of Engineers and the Geological Society of Belgium at Liege, in consultation with the societies which took part in the Conference at Dusseldorf The work of the Congress will be divided into three sections (*A*) Mining Section, which will include reconnaissance and pre liminary work, modern methods of working coal mines, metalliferous deposits and quarries, genera tion and utilisation of energy, extraction, ventilation (gas and dust), and mechanical treatment of ores and coal, (*B*) Metallurgy Section, which will deal with blast furnace practice, steel and ferrous alloys, foundry work, non ferrous alloys and fuels, (*C*) Applied Geology Section, covering metals, fuels, hydrology, and geophysical prospecting Further information can be obtained from the general secretary of the Organising Committee, 16 Quai des États Unis, Liège

EVER since its formation in 1884, the North East Coast Institution of Engineers and Shipbuilders has paid attention to engineering education, and in 1903 and 1907 it published reports on the training of apprentices After the reading of a paper in October 1926 by Sir T Morison entitled 'How should an Engineer be trained?", the Education Committee of the Institution was requested to consider the training of candidates for official positions in the engineering and shipbuilding industries, and, in a short but valuable report entitled "Engineering Training for Officer's Rank", the results of its inquiries have just been published 'Officer's rank' is considered to denote that a person possessing it has a reasonably broad acquaintance with the application of scientific principles to engineering, a certain amount of scholarship, and some practical knowledge of all the trades or professions which are employed in engineering works, while the report refers mainly to the training of marine and mechanical engineers, shipbuilders, and naval architects

THE Education Committee of the North East Coast Institution of Engineers and Shipbuilders regards the obtaining of a university degree in applied science as assuring a satisfactory standard of scholarship and as the normal road to officer's rank in the engineering profession, but one of the points stressed in the report is the desirability of a preliminary training in the works before the student enters upon his university course "It is extremely desirable, as a preliminary to entering the university, that some experience of handling and fashioning actual materials, and of seeing what engines and ships and their parts look like in different stages of their construction, should be acquired" This view was supported by 94 per cent of the firms to which a questionnaire was sent Appended to the report are outline schemes of training for both the shipyard and the engineering workshop The carefully considered views of the Committee will be read with interest by those teaching in technical schools and colleges, and the report should also be of value to parents of boys desirous of becoming engineers

THE opening of direct electrical communication between Madrid and Buenos Aires on Oct 12, 1929, marked the completion of a wonderful engineering feat for which the International Telephone and Telegraph Corporation deserves great credit The radio link installed is capable of connecting any telephone in the principal cities of Europe to any telephone in the principal cities of Argentina, Chile, and Uruguay The length of this link (6400 miles) is twice as great as that connecting Britain with the United States The radio path cuts the meridian at the equator at an angle of about thirty four degrees It passes through zones notorious for atmospheric disturbances and through the equatorial region where radio transmission is particularly subject to fading Devices have been installed to counteract the effects of fading and, in addition echo suppressor circuits which prevent the speech being reflected at the distant ends have been permanently installed In order to give a trustworthy service over the entire day, three wave lengths are used at each transmitter A wave length of 15 metres (20,000 kilocycles) is employed in the daytime, 20 metres for sunset and sunrise conditions, and 30 metre waves (10 000 kc) are used at night In order to reach Montevideo in Uruguay and some of the important cities in Argentina, it was necessary to place a telephone cable under a very broad portion of the River Plate and to cross some very high mountains where snow prevents train traffic at certain periods of the year Serious trouble has been experienced in Argentina where enormous cobwebs are blown by high winds into the circuits and effectively short circuit them In *Electrical Communication* for February many details are given of the system Extensions have been made to Chile, which will add

many cities in that country to the Buenos Aires Madrid link In two years' time the toll plant to Bogota will add Colombia to the system

The transmission systems for railway electrification which are used in the Swedish State railways are novel and deserve special study by railway engineers We therefore welcome a paper by I Ofverhohm, the chief electrical engineer of the State railways, which is published in the *ASEA-Journal* (Allmanna Svenska Elektriska) for December At the end of the year 1928, nearly six hundred miles of the State railways had been electrified and the electrified portion carried nearly a quarter of the whole traffic (in train-miles) of the railway system Owing to special reasons, alternating current was used The power required for the Kiruna—Riksgransen line, the so called Ore railway, is produced by separate generators at the Porjus power plant, which is then stepped up to 80,000 volts for the transmission lines which extend for 250 miles along the railway, the average distance between the substations being about 20 miles The southern part of the State railway from Stockholm to Göteborg, which is called the western trunk line, is supplied with electrical power from the national high voltage three phase transmission lines The voltage between the trolley wires and the earth in the Ore railway is 16,000 volts, and the frequency is only 15 The important difference between the two sections of the State railway is that for the Ore railway special transmission lines and transformer substations had to be constructed in addition to the trolley lines In the latter case it was only necessary to construct motor generator stations in addition to the necessary trolley wires One objection that has been often urged against the use of alternating current is that it would produce interference with telegraph and other communication circuits The Swedish engineers seem to have overcome very easily by various methods described in the paper any troubles arising from this cause

A Report on "Rational Organisation and Industrial Relations", which consists of a symposium of views by members drawn from the spheres of management, labour, and science, has recently been published (The Hague International Industrial Relations Association, 1930 3 50 fl, 6s, to Members of the Association, 2 50 fl, 4s) In a paper on "Rational Organisation", Mr L Urwick, director of the International Management Institute, Geneva, defines a rational or scientifically organised industry as a group of enterprises engaged in supplying similar or allied requirements to the community by methods involving the minimum waste of either effort or material Rationalisation, he holds, is both an attitude and a process As an attitude, it records the belief that a more rational control of world economic life through the application of scientific method is possible and desirable, As a process, it implies the application of scientific intellectual technique to all problems arising in the organisation and conduct of production, distribution, and consumption An important lesson which recent experiments in scientific management have to teach is that the art of management and of organising large bodies of men must be based on a searching intellectual study of the underlying sciences bearing on it, coupled with that power of synthesised expression which is the distinguishing hall mark of real ability Scientifically managed industry of the future will necessarily involve a substantial degree of workers' control, but the mechanisms and forms of that control would accord rather with the findings of comparative administration than with any political preconceptions "Personnel Policy and Procedure" is discussed by Dr C H Northcott, labour manager of Messrs Rowntree and Co, Ltd, who holds that management should not wait for the workers to make a proposal Even in such matters as wages, it is unfair to the workers that a grievance known to the management should remain uncorrected until complaints are made

In the *Engineer* for April 11 is an illustrated article on the s s *Seapro*, a fish treating vessel which has just sailed for the south west coast of Africa Fish of many kinds are caught in the waters in that area, some of which are only fit for conversion into food for cattle, pigs, and poultry, some of which are valuable for their oil content, others the livers of which provide medicinal oil, and shellfish that furnish a table delicacy when tinned Finally, there are other fish which are worth putting into cold storage for sale at any convenient market To deal with these various classes of fish, the *Seapro* has been fitted up as a factory with hacking machines for tearing the fish into small pieces, drying machines for expelling the water, sterilising machines in which the albumen is coagulated and bacteria killed by being subjected to high temperature, a complete tin making plant for making tins, and others for boiling and canning cray-fish and for boiling the oil out of fish livers The machinery, which is driven by electric motors, has been constructed by Rose, Downs, and Thompson, Ltd, of Hull, who specialise in the construction of fish meat plant The actual fishing will be done by a fleet of motor boats the crews of which will be recruited locally but who will live on board the *Seapro*, in which extensive native quarters have been provided The *Seapro* is a vessel of 5305 deadweight tonnage, and before being altered for her present purpose was, under another name, engaged in the pilgrim traffic in the East

The cost of books to the reader, relative to the publications of different countries and to succeeding years, is not easy to assess with strict accuracy, and on this account the statistics collected by John R Miner must not be pushed too far (*Quart Rev Biol*, p 598, 1929) They refer to the cost of the biological books received for review in 1929 by the journal mentioned If these may be taken as fair samples of national production, of the great nations Germany heads the list as the most expensive retailer (1 65 cents a page), followed by England (probably meaning Great Britain—1 29 cents), United States (1 14), and France (0 47) The cheapest of all biological books are those published by the United States Government,

and next to them appear to come those of the British Government, but this statement is founded on a single example only It is very striking, however, that during the four years of this annual survey, France has continued to produce the cheapest commercially published scientific books, costing on the average less than half as much as those of any other country In all countries 1929 was marked by rising prices, varying from an increase of 18 3 per cent in British books to 4 4 per cent in French, United States commercial books show no difference, but their Government publications have risen 9 5 per cent The longer view shows that while British and American books stand now practically at the price level of 1926, French books in the same time have increased in price 34 3 per cent and German books 51 4 per cent

Dr A Nodon has contributed an article to *Savoir* (Mar 15) which again raises the problem of the nature and origin of the cosmic rays It seems to be undecided at present whether they are electromagnetic waves or corpuscles Prof Millikan's interpretation of the accurate absorption curves obtained by him and by his collaborators is not everywhere accepted, but, on the other hand, the evidence that the rays are corpuscular is as yet not completely satisfactory Their place of origin, again, cannot be regarded as settled in the absence of more complete statistical analysis of the type made by A Corlin, the accumulation of data for which is necessarily a lengthy procedure Dr Nodon has directed attention to the work on the cosmic rays which has been done in France at various times since the discovery that there was a real residual ionisation in electroscopes The feature of the French work is that it tends to show that the penetrating radiation comes in part directly from the sun, and in part indirectly from the upper atmosphere, but not from the sun The present position is most unsatisfactory and it does not seem possible to pronounce any certain judgment on the questions at issue

The anthropological surveys carried out and planned by the Bernice P Bishop Museum at Honolulu promise to add much to the knowledge of the people of Polynesia The Museum was founded in 1889 as a memorial to the Princess Panahi, last of one of the branches of the chiefs of Hawaii, with the stated object of the advancement of knowledge of " Polynesian and kindred antiquities, ethnology, and natural history " It was recognised that the problems of anthropology should be given a preferred position owing to the rapidity with which, on the death of the older people and in the absence of written records, reliable sources of information regarding native language, music, myths, social organisation, industries, and history, disappear In carrying out the surveys, the investigators have, as it were, kept an eye on the clock, realising that vanishing data must be gathered at all costs, and that less urgent studies may well be excluded from the programme of immediate work For the purposes of the survey, Polynesia has been divided into twenty six areas, and eighteen surveys have been completed or organised In addition to its ethnographical work, the Museum has done much to elucidate the flora and fauna of the Hawaiian area

The Zoological Survey of India was a fine conception which took shape under the enthusiastic guidance of the late Dr Nelson Annandale, and the report for the years 1926–29 shows how solid is the foundation being laid for a knowledge of the fauna of India Concerned equally with the field work on which advance of knowledge must be based, with the preservation and storage of the materials collected, and with the identification of specimens, the Survey finds its labours hampered in several directions The director, Col R B Seymour Sewell, suggested, therefore, that besides additional staff, there was need for a fire proof building to house the collections, the library and laboratories, and of a marine biological station at Karachi Force of circumstances has prevented the completion of these projects, but the appointment of an anthropologist should be of great service from the point of view both of the public galleries and of the scientific collection of data Field work has been carried on in various areas, and now that the Chilka Lake survey has been completed, attention has been turned particularly to the fauna of the Nerbudda River Appendices, occupying 44 pages, give lists of collections sent out and received, of an impressive series of type specimens added, of papers published, and so forth, but in these days of expensive printing, full lists of specimens added to the exhibited collections, of odds and ends received for identification, or of workers who used the library or laboratories, might be omitted without serious loss

The Zoological Society of London has had another most successful year According to the Report for 1929, the number of visitors shows a decline from that of the previous year and the realised profit has fallen But the former still exceeds two millions, and the latter, at £12,059, is in reality an improvement on the previous year, since there has already been debited against profit a non recurrent loss of £2742 due to the centenary celebrations The number of animals in the collections remains much the same as before—4095, excluding fishes and invertebrates—and this in spite of an abnormally high mortality amongst small mammals and birds which took place during the exceptionally severe and prolonged frost in January and February of last year Otherwise the collections show a wonderful freedom from disease, for we can reckon out of count the deaths of thirteen penguins imported from the Falkland Islands in an infected condition The gratifying decrease of tuberculosis, to which we have referred before, continues, the records showing ten cases fewer in mammals and eleven in birds, with only two cases amongst the Primates, as against forty one in 1926 amongst the inhabitants of the old ape, monkey, and lemur houses—a fine justification of the new housing policy In view of the scare regarding psittacosis, it is reassuring to learn that no case of this disease has been detected and no outbreak of epizootic disease has occurred in the Society's aviaries during the year To the Report are appended the addresses by His

Grace the Duke of Bedford and Sir P Chalmers Mitchell at the centenary celebrations, as well as shorter addresses by three representative delegates

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A temporary technical assistant in farm economics under the Department of Agriculture for Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (May 10). Designers with experience in the design and construction of light precision mechanical or electrical machinery, for an Admiralty establishment near London—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (May 10) A physiological botanist under the Director of Agriculture, Mauritius—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S.W 1 (May 16) A university librarian for the Queen's University, Belfast—The Secretary to the Library Committee, Queen's University, Belfast (May 16) A head of the Building Department of Leeds Technical College —The Director of Education, Education Department, Calverley Street, Leeds (May 17) A senior science master at the City of Leeds School—The Director of Education, Education Department, Calverley Street, Leeds (May 17) A chief assistant in the Pottery Department of the North Staffordshire Technical College — The Clerk to the Governors, North Staffs Technical College, Town Hall, Hanley, Stoke on Trent (May 19) A junior lecturer in the department of inorganic and physical chemistry of Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N W 1 (May 24) An assistant horticultural adviser to the County of Southampton Education Committee —The County Education Officer, The Castle, Winchester (May 24) An assistant director of agricultural education, a senior agricultural advisory officer, and a poultry advisory officer—The Director of Agricultural Education, Agricultural Station Offices, Sprowston, Norwich (May 24) A head of the mathematics and physics department of the Birmingham Central Technical College—The Principal, Central Technical College, Suffolk Street, Birmingham (May 30) An assistant lecturer in the department of mathematics of the University College of Swansea—The Registrar, University College, Swansea (May 30) Assistant meteorologists under the India Meteorological Department—The Director General of Observatories, India Meteorological Department, Poona 5, India (June 29)

Our Astronomical Column

Double Star Measures at Johannesburg — *Circular* No 80 of the Union Observatory is wholly occupied with double star measures made by Mr W H van den Bos There are 1393 measures of 604 pairs, the 9 inch refractor is used for such pairs as are within its reach, the 26½ inch for more difficult ones Some pairs within reach of northern observers are measured for a check on personality in measuring One of these is Sirius, there are five measures of the principal pair *AB*, which agree closely with the ephemeris from Aitken's orbit, two measures of the suspected third companion *C*, date 1929 213, give P A from *B* 132 6°, distance 1 54", the note on one night is "*C* sharp and stellar regarded as quite certain, good measure", but a later note states that the real existence of *C* is still regarded as doubtful A bar across the object glass was found to aid observation in this case, there were dark lanes between the diffracted patches of light, a faint object in these lanes was more easily seen, it is suggested that the device might be useful for Procyon Three companions of Nova Pictoris were measured, position angles, 70°, 230°, 10°, distances, 0 5", 0 6", 0 3", dates not given An interesting new close pair is ν Indi, magnitudes, 6 1, 6 2, P A 0°, distance 0 14" As this star has a parallax of 0 034" (Voute), it is likely to show orbital motion With the circular are issued twelve more sheets of the photographic star atlas of the southern heavens that is being made with the Franklin Adams camera, they are ruled with the lines of R A and Decl for the equinox of 1875

A New Determination of the Galactic Pole —*Publication* No 43 of the Groningen Laboratory, by Prof P J van Rhijn, director of the Laboratory, is taken up with a careful analysis of the distribution of the faint stars, based chiefly on the photographs of the Kapteyn selected areas, but supplemented by the Franklin Adams photographs and some other sources The stars used are very much fainter than those employed in obtaining the galactic co ordinates that are in common use, it is therefore not very surprising to find that the new position of the galactic pole differs considerably from accepted values Thus, in the analysis the preliminary position of the galactic pole was that derived by Gould, R A 12h 42m 34s, N Decl 27° 13', that finally adopted is 12h 56m, N 25° 30' (both are for the equinox of 1900) The publication contains tables for reducing R A and Decl to this new system, the remainder of it contains extended tables of the logarithms of the star density for different magnitudes and in different regions of the sky The important result is deduced that the ratio of increase in the number of stars on extending the table from any magnitude (between the limits 15 and 18) to a value half a magnitude fainter is independent of the galactic longitude, and is the same on both sides of the galaxy

Melbourne Astrographic Catalogue, Vol 3 —This catalogue has just been published under the direction of the present Government Astronomer, Mr J M Baldwin, most of the photographs were taken and measured under his two predecessors, Messrs Ellery and Baracchi It covers the zones − 69° and − 70°, so that about half the stars in it occur twice, since each plate covers 2° in declination There are 254 pages, and the average number of stars on each page is about 200 The diameters of the star images are given, and a table in the introduction gives the magnitude corresponding to each diameter the faintest stars are of magnitude 12 9 The rectangular co ordinates *x*, *y* of each star are given to the third decimal of a minute, there are tables to facilitate the reduction to Right Ascension and Declination The stars used for the plate constants are in heavy type The reference numbers in the Cape Photographic Durchmusterung are given for all stars contained in that work, together with their magnitudes The Melbourne section of the catalogue extends to the south pole, but the zones near the pole are very small, so that about half the whole area has now been published

Research Items

Polynesian Anthropometry.—Prof. Wood Jones prefaces a discussion of the anthropometry of the Polynesians in *Man* for April with certain preliminary considerations which he commends to the attention of anthropologists. First, that the question of the origin of the race has been obscured by a tendency to confuse the point of their mixed origin with that of a tendency to hybridisation shown in the agelong toleration of admixture with alien blood; secondly, that anthropologists have neglected the methods of their fellow workers in other branches of zoology, though recently Sir Arthur Keith has brought the study into line by regarding human races as varyingly perfected stages of human evolution; thirdly, correlation of growth must not be overlooked; for example, the correlation in length of vertebral column, base of skull, and maximum head length. Turning more specifically to Polynesia, can anthropometric methods demonstrate, aside from recent admixture, the original blending of separate racial elements in the formation of a Polynesian type? Sullivan's observations were summed up by him as demonstrating two races in Polynesia. This was based on a method of selecting one characteristic and noting the status in a series in regard to other features; thus from an examination of "23 tallest men", "21 shortest men", and so forth. But in view of the zoological principle mentioned above, the results probably denote no more than that they represent the tallest and shortest individuals with the usual correlations of head and face. The same distinctive classification is obtainable from Burton's tables of Australian aborigines, but no one would suggest that this homogeneous group is derived from the crossing of two racial strains. The same criticism applies to the frequently repeated classification of the bones and skulls found in English Church crypts into 'conquerors' and 'conquered'—'Romans' and 'British', 'Saxons' and 'Danes'.

Origin of the Caste System in India.—In the *Indian Antiquary* for March is published the first instalment of a discussion of the origin of the caste system in India by the late Mr. Charles Hill. The civilisation of India is utterly different from any other type in the world. The word 'caste', of Portuguese origin, means 'purity'. The system is aristocratic in that birth is considered essential to the possession of certain qualities, yet it is democratic in the fact that theoretically the members of all the groups are on an equal footing. Expulsion, which follows on any cause, however slight or accidental, leads to the formation of a new caste when the breach is great or intentional, or a sub-caste when it is slight and accidental. The result is that there are now more than 2000 castes and sub-castes. According to tradition, the Hindus were originally divided into four castes only—Brahmans, a spiritual priesthood, Kshatriyas, warriors sprung from the arms and shoulders of Brahma; the Vaisyas, who provide the food, clothing, and other necessities of man, born of the belly of the god; and the Sudras, whose lot is servitude and issue from his feet. The first three are 'twice born' and wear the sacred thread, though the Vaisyas receive it only on marriage. All Hindus belong to one or other of these four original castes or classes. Though similar to classes which once existed in Persia, Egypt, and Arabia, they survived in India only. It is suggested that the caste system was inaugurated as a method of securing stability at a time of social upheaval, such as would have occurred when the rulers of the Aryans entered India after being expelled by force from their earlier home. That the caste system did achieve such stability is shown by the tenacity with which Hindus cling to it while exhibiting apathy to all forms of government and changes in it. The formation of new castes strengthens the bonds of caste, for all are equally a manifestation of Brahma, though of different qualities.

Manchurian Rodents and Disease.—In the steppes of Asia rodents play a significant part in the web of Nature, mainly on account of their enormous powers of multiplication. The tunnelling of underground burrows, the destruction of vegetation, and the tilling of the soil are all important activities, but for man their most vital part is that of possible disease carriers. It is undoubted that the sudden vanishing of many rodent plagues is due to epizootics, and many substantial reasons suggest that the epizootics occurring among the rodents of the steppes are associated with the spread of bubonic plague, which visits the region almost every year. With this possible association in view, Dr. Wu Lien Teh, chief of the Manchurian Plague Prevention Service, Harbin, has published a useful account of the biology and pathology of the wild rodents found in Manchuria and Mongolia (*Bull. Pekin Soc. Nat. Hist.*, vol. 4, No. 2, p. 95, December 1929). Several of the rodents, such as the tarabagan (*Arctomys bobac*), the spring hares (*Alactaga* and *Dipodipus*), various voles, rats, and mice, have already been found to be susceptible to plague under natural conditions. Moreover, by harbouring plague during hibernation, some carry over infection from one plague season to another. It has been shown that domestic rats play an important part in the spread of the plague outbreaks, and attention is now being turned to the investigation of the source of the domestic rat infection, whether or not it may be connected with wild rodents.

Fluctuations of Manitoban Grouse.—For several species of animals it has now been shown that numbers fluctuate with a fairly regular rhythm, although the periodicity appears not to be identical for all species. To the growing list of regular fluctuations Norman Criddle would add the sharp-tailed grouse and ruffed grouse in Manitoba (*Canadian Naturalist*, April, p. 77, 1930). The years of plenty of these he associates with abundant locust years, and traces the relationship through the fact that grasshoppers are apparently necessary food for the young of the grouse. The reduction in numbers which follows years of abundance he suspects may be due partly to disease and perhaps partly to the activities of enemies, such as goshawks. But has the author proved his point about periodicity at all? His observations from 1914 to 1929 on the numbers of ruffed grouse nesting upon a 26 acre wood lot clearly do not establish a rhythm, for if a rhythm exists, it approaches a ten-yearly period, and the observations cover only sixteen years. On the other hand, the graph showing the annual fluctuations of grasshoppers, sharp-tailed and ruffed grouse from 1895 to 1929 at Aweme, Manitoba, looks convincing with its three series of peaks occurring at intervals of ten years. But the figures upon which this interesting graph is based are not stated, and we are left to understand that it represents no more than an ideal representation of the general notes in a series of journals, and therefore, that its details and fine agreements have no numerical sanction. More should have been said about the character of the information upon which the graph and consequently the conclusions are based.

Rooting of Woody Cuttings—Very contrary reports have been given by different investigators as to the effect of the buds upon the production of roots on hardwood cuttings Van der Lek has recently described experiments which suggest that in willow, currant, and vine the production of roots is more rapid upon such cuttings when the buds are left upon them He suggested that 'hormones' released from the developing buds might be responsible for this effect W A Sledge points out, in a paper in the *Journal of Pomology*, Vol 8, No 1, January 1930, that root production in such cuttings is closely connected with cambial activity He re examines root production in cuttings from this point of view and confirms an early observation of Hartig that cambial activity begins on the shoots at the base of the buds and works from thence down the stem In these cuttings, however, cambial activity is also resumed at the base of the cutting as the result of the wound, such cambial activity being quite independent of the presence of buds, as is shown by an examination of internodal cuttings, in which also cambial activity occurs at the proximal end of the isolated internode Root production seems certainly associated with this renewal of cambial activity and the effect of the buds in enhancing root production in Van der Lek's experiments may be associated with the renewed activity of the cambium throughout the length of the cutting as the result of the early development of the buds

Radioactivity of Granites and Granodiorites—Dr H Hirschi has recently published in the *Schweiz Min und Pet Mitt* determinations of the radioactive elements in three important groups of plutonic igneous rocks The results are summarised in the table below, the detailed references being as follows (1) "Radioaktivität der wichtigsten Granitmassen des Gotthardmassivs" Bd 8, Heft 2, 318 320, 1928 (2) "Radioaktivität des Albtal und Schlossberg Granits des sudlichen Schwarzwaldes" Bd 8, Heft 2, 321 322, 1928 (3) "Radioaktivität einiger Tiefengesteine vom nordlichen Baja California" (Mexico) Bd 9, Heft 1, 1 2, 1929

The Golconda Diamond Mines—The first issue of the newly established *Journal of the Hyderabad Geological Survey* contains the annual report of the Survey, but is mainly devoted to a geological and historical account by Capt L Munn of the ancient diamond mines of Hyderabad, Golconda was formerly the capital of this State Capt Munn's compilation is supplemented, through the courtesy of the Royal Society, by a reprint of a paper on the subject read before the Society by the Earl Marshal of England in 1677 Up to the year 1728, this region was the sole source of the world's supply of diamonds, the Great Mogul or Koh i noor being among the more famous of the later finds The earlier wealth has become proverbial and was responsible for the fabulous tales of Sindbad the Sailor and Marco Polo The diamonds are found in the Pre Cambrian Banaganpilly Group of quartzites and pebble beds occupying a low position in the Vindhyan system, and it is noteworthy that at Wajra Karur "an igneous pipe, or neck, of bluish tuff like rock exists" No gems have been extracted from this pipe and the real source is probably hidden beneath the Deccan traps In 1890 a modern attempt to exploit the 'mines' was made, and 3444 stones were extracted before the enterprise was closed down in 1894 as being unprofitable

Silica Glass at Meteor Crater—A remarkable occurrence of lechatelierite or silica glass produced by the fusion of a saccharoidal sandstone at the bottom of the depression of Meteor Crater in Arizona is described by A F Rogers in the *Am Jour Science*, March, 1930 The only rocks in the immediate neighbourhood are sandstones, shales, and limestones, the nearest exposed igneous rocks being ten miles away A temperature of between 1400° and 1800° C was required to transform the quartz into silica glass The latter occurs in comparatively large masses up to 15 cm in thickness and could not have been formed, like fulgurites, by lightning It is equally impossible that silica glass could be produced by a steam explosion Barringer's well known hypothesis that the crater was formed by the impact of a huge meteorite thus receives strong support, for no other explanation has been advanced that would equally well account for the melting of some parts of the sandstone floor and the shattering of other parts into a finely comminuted rock flour

A 100-Ton Testing Machine—In the *Engineer* for April 4 is an illustrated description of a new 100 ton electrically operated testing machine, which has been supplied by W and T Avery, Ltd, to the City of Leicester Colleges of Art and Technology The machine is of the compound lever type For tension tests it will take specimens up to 10 ft in length and 3 in in diameter, for compression tests, specimens 10 ft in length and up to 12 in square, and for bending tests specimens from 4 ft to 14 ft can be accommodated with a maximum width of 16 in The straining crosshead is moved by three straining screws on the end of each of which is a spur wheel driven by a main worm reduction gear which in turn is coupled to a gear box driven by a reversible variable speed electric motor The crosshead can be moved at speeds varying from $\frac{1}{10}$ in to 8 in per minute The scale on the steelyard is machine engraved from zero to 100 tons by divisions of 1 ton, and a micrometer screw dial subdivides these readings into $\frac{1}{100}$th ton divisions Mounted on the top of the steelyard column is an autographic recorder

Quantitative Analysis by X-Rays—The April number of the *Proceedings of the Royal Society* contains a paper by C E Eddy and T. H Laby on the quantitative analysis of alloys by means of their X ray emission spectra (see also NATURE, April 5, p 524) The fundamental assumption made is that the ratio of the number of atoms of two elements in an alloy

is equal to the ratio of the intensities of corresponding lines in the X ray spectra of the elements, provided that the lines are excited under equivalent conditions, and that the elements are nearly equal in atomic number The experimental determination of the relative intensities of the lines is made by making the alloy the target of an X ray bulb, and analysing its emission spectrum by a rotating crystal spectrometer with photographic registration, the blackening of the X ray film, as measured by a Moll recording microphotometer, being correlated with the corresponding intensity of the X-rays by the usual methods In general, Prof Laby and Mr Eddy's results are more satisfactory than those of earlier workers in this field They have paid some special attention to alloys in which the element to be estimated is present to the extent of less than one per cent, to which it is often difficult to apply other methods of analysis, especially when only small samples of material are available, and have also obtained good results for traces of lead in zinc, a case in which the elements differ widely in atomic number and for which a modified method had to be devised

Measurements at High Voltages – The amount of power absorbed by the dielectric in an electric cable when working under various conditions is considered by many manufacturers to give valuable information as to the quality of the cable In a paper on low power factor measurements at high voltages, which was read to the Institution of Electrical Engineers on April 4, Dr E H Rayner, W G Standring, and R Davis, of the National Physical Laboratory, give a critical study of the various methods adopted in practice for measuring these dielectric losses When a high voltage is applied to unloaded mains, the ratio of the power absorbed to the product of the volts and amperes, that is, the power factor, is generally very minute In this case the measurement of power presents many difficulties, as a small difference in the phase angle between the current and the pressure may make a large difference in the power measured A standard air condenser, the difference between the plates of which is variable, has been constructed It is suitable for use with 100 kilovolts When the distance between the plates is 10 cm, the capacity, or, as it is now called, the capacitance, is 500 c g s units This condenser, when used with a Schering bridge, is found to give very accurate results When using wattmeter methods of measurement, it was found that the non inductive resistances or 'resistors' were often affected by stray capacitance currents These errors could be eliminated if the resistor were shielded at every point by an electric field maintained at its own potential The resistor used consisted of water flowing in tubes, and these were surrounded by others at the same potential It was found possible by this compensation to keep the electric current in the water in phase with the applied voltage Compared, however, with the air condenser, a resistor using a closed water circuit was relatively a troublesome piece of apparatus to use During the experiments, the resistivity of the water was well maintained at 30,000 ohms for four months

Carbonisation Tests —It is frequently important to be able to estimate the value of a coal for carbonisation purposes by tests which can be carried out in the laboratory All such tests exhibit the defect that large scale results cannot be exactly reproduced, and certain factors are necessary to correlate these with laboratory results The Gray King assay was devised at the Fuel Research Station for the evaluation of coal for purposes of carbonisation at low temperatures —600°—and the appropriate correlation has already been made In *Fuel Research Technical Paper*, 24 (H M S O 1930, 9*d* net), an account is given of a modification of the assay whereby higher temperatures are used and conditions conducive to secondary decomposition in the retort are provided Factors which enable the results obtained with this new apparatus to be interpreted in terms of gas works carbonisation have been determined

Fires in Bunkers and Cargo Coal —The transport of coal by sea is fraught with a serious hazard of fire which continues to take a heavy toll in spite of generations of experience, and although radio communication has removed the worst terrors The hazard has been the subject of repeated inquiry, and again, recently, by the Fuel Research Board, which has investigated 336 fires in bunkers and cargo coal in 272 ships (*Fuel Research Special Report*, No 5, London H M Stationery Office 2s) The net result of this inquiry is that 86 per cent of these fires could be assigned to definite and ascertainable causes, avoidable by suitable precautions Only 14 per cent of the accidents were so unaccountable as to leave unavoidable spontaneous combustion as the only assignable cause All fuel is liable to spontaneous combustion under certain conditions which coal chemistry has brought to light, and it seems that this fire loss is one which could almost be avoided by the application of existing knowledge Shipbuilders might remove hot pipes and other sources of heat from bunkers or holds and design ventilation systems so as to avoid leading air into large masses of coal in confined spaces Shipowners might maintain bulkheads sound and tight Certain precautions might be taken at coal staithes in the loading and trimming of coal In short, a little scientific knowledge might leaven the practice of coal handling and, to judge from this report, a handsome dividend should accrue to both shipowners and underwriters

Utilisation of Salt-Lake Deposits —The great mineral wealth which is available in the form of salt lake deposits in various lands has up to the present, been very incompletely utilised, except for the extraction of ordinary salt Prof B Panteleymonoff, of the Academy of Sciences in the Ukraine, contributes an article to the *Chemiker Zeitung* of Feb 22 on the progress which has been made since 1923 in the exploitation of Russian salt lake deposits at the Rapa works The article is written exclusively from the industrial point of view, and is not concerned with the great mass of purely scientific work which has already been carried out there Among the problems investigated on the technical side is the production of compounds of magnesium and halogens The magnesia obtained is of a high degree of purity Iodine appears to be confined to those lakes which are in the neighbourhood of petroleum deposits, and the problem of its satisfactory extraction has not been completely solved The possibility of the early exhaustion of the iodate deposits in Chile lends interest to this problem Magnesium chloride is perhaps the most important of the products obtained, owing to the fact that its extraction leads up to the production of potassium chloride and magnesium sulphate from the mother liquors The extraction of magnesium chloride from salt lake deposits is a more difficult problem than that of its production as a by product of the Stassfurt deposits Bromine is either extracted with a solvent or recovered by distillation The systematic design and development of undertakings for the utilisation of these deposits is of exceptional interest not only in Russia but also in America, France, Italy, and other countries which possess salt mines

The Unsaponifiable Fraction of Certain Oils

IN attempting to concentrate the fat-soluble vitamins, investigators submitted the fats or oils containing them to saponification, and found that they passed unchanged into the unsaponifiable fraction Subsequent work, especially in connexion with vitamin A, has led to increased knowledge of the constituents of this fraction of a number of natural oils and fats, although the identification of the vitamin itself has not been successful At the same time a certain amount of attention has been directed to the physiological functions of some of these constituents It may be of interest to review briefly some of the more recent work on this subject

FISH OILS CHEMISTRY

It is only natural that the unsaponifiable matter of cod liver oil should have been thoroughly investigated, considering its importance as a source of supply of vitamins A and D, much attention has been devoted to it, especially in Great Britain and Japan Its content of unsaponifiable matter is, however, only small, about 0 7 per cent of the oil, and half of this consists of cholesterol In the other portion, Drummond and his colleagues have identified small amounts of squalene $C_{30}H_{50}$, and batyl alcohol $C_{21}H_{44}O_3$ they also found a small quantity of a hydrocarbon (unidentified), but considered that the main constituents are one or more unsaturated alcohols, possibly oleyl or selachyl alcohols (J C Drummond, H J Channon, and K H Coward, *Biochem J*, vol 19, p 1047, 1925, J C Drummond and L C Baker, *ibid*, vol 23, p 274, 1929) Nakamiya and Kawakami (*Scient Papers, Inst Chem Phys Res*, vol 7, p 121, 1927) claim to have isolated, amongst other products after the hydrogenation of the cod liver oil concentrate, nonacosane $C_{29}H_{60}$ and batyl alcohol, but the identified compounds constitute only a small portion of the whole They were, however, unable to detect squalene in their samples of cod liver oil Weidemann considers that the alcohols present are more unsaturated than selachyl alcohol (*Biochem J*, vol 20, p 685, 1926)

Certain other fish liver oils contain larger amounts of unsaponifiable matter, which is more easily fractionated than that obtained from cod liver oil That from the Greenland shark has been investigated by, amongst others, Drummond and Baker (loc cit) and Weidemann (loc cit) It contains about 15 per cent, of which cholesterol constitutes only about 14 per cent Squalene is present in minute amounts (0 5 per cent of the unsaponifiable matter), the rest of this fraction consists chiefly of batyl (about 20 per cent), selachyl ($C_{21}H_{42}O_3$) and oleyl ($C_{18}H_{35}OH$) alcohols The presence of the last two was indicated by the detection of batyl, and probably octadecyl, alcohols after hydrogenation

The liver oil of the Japanese shark contains about 5 per cent unsaponifiable matter Small amounts of cholesterol and possibly squalene were detected, chimyl alcohol ($C_{19}H_{40}O_3$) is present to the extent of about 20 per cent, whilst the rest of the fraction is composed chiefly of selachyl alcohol

Drummond and Baker reduced chimyl alcohol with hydriodic acid and obtained cetyl iodide and isopropyl iodide their results indicated that the alcohol is a monoglyceryl ether of cetyl alcohol Heilbron and Owen have shown that batyl alcohol is an ether of octadecyl alcohol and glycerol, it probably has the formula $CH_3 (CH_2)_{17} O CH (CH_2OH)_2$, since it is optically inactive (Drummond, *Chem and Ind*, vol 49, p 1, T, 1930)

The hydrocarbon squalene contains six double bonds, it forms a characteristic hexahydrochloride by which it can be easily identified Channon has investigated its distribution in certain fish, and found it to be present in the liver oils of only three members of the Squalidæ family it has, however, also been found in the livers of certain Japanese elasmobranchs (*Biochem J*, vol 22, p 51, 1928) It seems unlikely that it can be derived from the food, in any case it was not found in the samples of plankton examined The unsaponifiable matter of the liver oils of these fish formed a very high proportion of the oil, 67 73 per cent, other fish contained up to 33 per cent In general the unsaponifiable fraction was considerably greater than in mammalian livers It was noticed that in the Selachii there was an inverse relationship between the amount of unsaponifiable matter present and its sterol content, independent of whether squalene was present or not There appears to be no relationship between the sterol and squalene

FISH OILS PHYSIOLOGY

Channon has investigated the results of administering certain of these higher alcohols and squalene to mammals He found that rats absorbed a certain amount of the latter when fed in daily doses not exceeding 0 075 c c a day or mixed to the extent of 1 per cent in the diet In some of the experiments the fæces were collected during their course and worked up at the end with the livers and bodies of the animals, in others, only the livers were examined for the presence of squalene (*Biochem J*, vol 20, p 400, 1926) The fæces were extracted with alcohol and ether, and the extract then treated as the other material Saponification was followed by ether extraction of the unsaponifiable matter, which was again saponified and the solution extracted with ether Cholesterol was removed with digitonin and the mother liquors extracted with ether The residue, after removal of the solvent, was again dissolved in ether, and dry hydrochloric acid gas passed through the solution The squalene hexahydrochloride so obtained was recrystallised from acetone In one experiment, 2 77 gm squalene were given to each rat over a period of 6 weeks, 1 7 gm was excreted The unsaponifiable matter in the liver was increased up to 2½ times that in the controls on the same diet and was half as much again in the carcass (without liver) The cholesterol content in the liver was doubled The squalene actually recovered from the liver, however, only accounted for about half of the unsaponifiable matter left after removal of the cholesterol The increase in the cholesterol with increase in the total unsaponifiable matter is the reverse of the relationship found in the fish oils mentioned above

In further experiments with Collinson (*Biochem J*, vol 22, p 391, 1928) it was found that rats absorbed about 0 045 gm daily of oleyl alcohol and phytol, 0 03 gm up to 0 09 gm of cetyl alcohol, and 0 017 gm of cholesterol the two latter were given in dispersion in olive oil Phytol appeared to be more readily absorbed than oleyl alcohol These two increased the amount of unsaponifiable matter in the liver, and at the same time the cholesterol content was raised Cetyl alcohol had no influence upon this fraction of the liver fat The administration of cholesterol increased it four times, and the whole of this increase was accounted for by the deposition in the organ of cholesterol itself It was also observed that the solubilities of these alcohols in bile follow the same order as the degrees to which they are absorbed From some experiments of Mellanby with emulsified fat and squalene, it appears that particulate absorp-

tion of fatty substances may occur in the intestine, but only in the presence of bile

These results led to a re examination of the question as to whether liquid paraffin can be absorbed from the gut, rats and a pig were used (Channon and Collinson, *ibid*, vol 23, p 676, 1929) Reliance was placed on the iodine value of the unsaponifiable fraction of the liver, together with an estimation of its cholesterol content to determine the presence of paraffin in this organ The rats were given 5 per cent paraffin in the diet for five weeks, the pig 100 c c daily, mixed with gum acacia mucilage and a little food, for about eight weeks The unsaponifiable matter in the livers of the paraffin fed rats was increased 40 per cent, the cholesterol percentage was reduced, but the absolute amount was unchanged as compared with the controls, the iodine value of the non sterol fraction was 31 instead of 119 Similar results were obtained in the case of the pig, in addition, a saturated hydrocarbon was actually isolated The non sterol fraction (expressed as a percentage of the liver weight) was increased $3\frac{1}{2}$ times in the rats and $2\frac{1}{2}$ times in the pig, but its iodine value in the latter was decreased to a third of that of the control

MAMMALIAN OILS AND FATS

Channon and Marrian have found an unsaturated hydrocarbon in mammalian liver, which is probably not squalene, although closely allied to it (*Biochem J*, vol 20, p 409, 1926) The unsaponifiable material was prepared from the livers of the pig, sheep, ox, horse, and man, the yields were 0 3 0 4 per cent More than half of the material consisted of cholesterol, and pigments were also present The hydrocarbon was obtained as a crystalline hydrochloride or an amorphous bromide, both of which are insoluble in ether, whereas the cholesterol compounds are soluble, by use of either method the hydrocarbon can be separated from the latter Considerable purification was effected by making use of the fact that the hydrocarbon is insoluble in methyl alcohol, but it was not obtained in the pure state It could not be distilled at 2 mm Hg pressure, decomposition occurring The hydrochloride and bromide were analysed, but molecular weight determinations could not be carried out, since the hydrocarbon was not prepared in the pure state, and the salts are very insoluble and decompose at high temperatures No squalene was found in these livers The same hydrocarbon has also been detected by Drummond and Baker (loc cit) in sheep liver fat

Certain members of the petrel family store in their stomachs an oil, to which attention has been directed from the fact that it contains vitamins A and D Rosenheim and Webster have examined the stomach oil of the fulmar petrel, which breeds on St Kilda (*Biochem J*, vol 21, p 111, 1927) It was found that the oil is a liquid wax containing nearly 40 per cent of unsaponifiable matter, unsaturated higher alcohols and clupanodonic acid were found to be present, but there was only a small amount of glycerol, cetyl alcohol was not detected In many respects the oil resembles sperm oil The authors suggest that the bird uses the oil as a preening material Both vitamins A and D were present

Leigh Clare has also found vitamin D in the stomach oil of the Australian petrel or 'mutton bird' (*ibid*, vol 21, p 725, 1927) Carter and Malcolm have also carried out investigations on mutton-bird oil (*ibid*, vol 21, p 484, 1927) They consider that it consists largely of cetyl oleate together with esters of related alcohols and acids, it contains only traces of glycerol and little cholesterol The origin of the oil is obscure Experiments indicated that it could be digested *in vitro* by pig's pancreatic lipase, and that small amounts could be absorbed by the cat or the rat, cetyl alcohol in olive oil was also absorbed by the latter animal, a result which was confirmed later by Channon and Collinson, as mentioned above Carter and Malcolm suggest that the presence of the oil in the stomach may be accidental, and that it is the tail gland secretion which has been swallowed

ETHER SOLUBLE SUBSTANCES IN PLANTS

Channon and Chibnall have investgated the ether-soluble substances of cabbage leaf cytoplasm (*Biochem J*, vol 21, pp 225, 233, 479, 1112, 1927 vol 23, pp 168 and 176, 1929) The material was prepared by mincing the leaves with water and squeezing through silk, the filtrate was then heated to 70°, when the cytoplasm was coagulated, and could be collected and pressed to free from excess water The dried material was powdered and extracted with ether From a third to a half of the total cytoplasm was extracted from the leaf, the ratio of the protein to the ether soluble substances present is 3 to 1 The total amount of the latter in the leaf cytoplasm is about 3 5 per cent of the total leaf solids Further fractionation was obtained by the use of solvents, soluble in acetone ether but insoluble in light petroleum are the pigments, chlorophyll 9 3 per cent, carotin 0 5 per cent, and xanthophyll 0 8 per cent of the total ether soluble material, soluble in ether acetone and light petroleum, the glycerides and waxes—the fatty acids accounting for 17 5 per cent and glycerol for 1 3 per cent, and unsaturated unsaponifiable matter consisting of sterols 4 5 per cent, and unidentified compounds, probably alcohols and hydrocarbons 13 3 per cent The fraction insoluble in ether acetone could be subdivided into a fraction insoluble in hot acetone — calcium phosphatidate 18 4 per cent, unidentified calcium salts, possibly of fatty acids and phosphoric acid 5 0 per cent, and an unidentified iron compound 3 0 per cent, and a fraction soluble in hot acetone, the saturated unsaponifiable matter consisting chiefly of nonacosane and di n tetradecyl ketone, 12 3 per cent There is an apparent loss of 14 per cent during the fractionations the greater part of which is due to mechanical working losses, but it is possible that 5 per cent represents some other compounds, possibly hydroxyacids

In the glyceride fraction, the results obtained suggested that palmitic, stearic, linolenic, and linolic acids were present, and possibly oleic acid also, palmitic accounted for two thirds of the saturated acids and stearic for the remainder The yield of fatty acids was higher in winter cabbage, that of the saturated unsaponifiable matter lower in winter than in summer

Considerable attention was directed to the phosphatides, little if any phospholipin was detected, the major part of the ether soluble phosphorus being present in the form of the calcium salt of a diglyceride phosphoric acid The free acid and its lead salt were prepared, and barium glycerophosphate was also made from the former The fatty acids present in the molecule appear to be stearic, palmitic, linolenic, linolic, or possibly oleic The greater part of the acids in the molecule is unsaturated, whereas in lecithin and kephalin saturated and unsaturated acids are present in equimolecular proportions The authors consider that phosphatidic acid may be a precursor of the lecithin and kephalin found in animal tissues rather than an *in vitro* decomposition product There is already evidence in existence that calcium can be extracted from tissues with the kephalin fraction The acid is a brownish oil, soluble in organic solvents, slightly soluble in water, the sodium salt is soluble in water, slightly soluble in cold alcohol, and insoluble

in ether, the barium, calcium, and lead salts are insoluble in water, acetone, and alcohol, but soluble in ether

Nearly one-half of the phosphatide fraction is soluble in hot acetone After purification by saponification, recrystallisation, and distillation, a material resembling paraffin wax was obtained, but the melting point was indefinite, indicating that it was a mixture By fractional distillation at 0 1 mm pressure and crystallisation from benzene alcohol, the hydrocarbon $C_{29}H_{60}$ was obtained in the pure state The formula was confirmed by X ray analysis The higher boiling fractions from the distillation were treated with hydroxylamine, the ketoxime was separated from the hydrocarbon by means of its greater solubility in light petroleum and acetone, and the ketone finally regenerated by boiling in hydrochloric acid alcohol X ray analysis indicated that it was either $CH_3(CH_2)_{13}CO(CH_2)_{13}CH_3$ or $CH_3(CH_2)_{14}CO(CH_2)_{12}CH_3$, both were accordingly synthesised, when it was found that the substance was di n tetradecyl ketone Nonocosane and the ketone occur in the ratio of 3 to 1 Small quantities of other unidentified substances are also present in this fraction of the cytoplasm

Maclean and her co workers (*Biochem J*, vol 23, pp 107 and 634, 1929) have also isolated from cabbage leaves nonacosane and di n tetradecyl ketone, from spinach leaves, however, the hydrocarbon hentriacontane, $C_{31}H_{64}$, was obtained

In conclusion, it may be mentioned that Maclean has isolated from yeast fat a second sterol which she has named 'zymosterol' The crude sterol was separated, by recrystallisation from alcohol, ether, and acetone, into the less soluble ergosterol, m p 158 5°, and a sterol, m p 108° 109° (zymosterol) (*ibid*, vol 22, p 22, 1928) The latter is dextrorotatory (in ethereal solution), the former lævorotatory (in chloroform) It probably has the same number of ethenoid linkages as ergosterol and a very similar structure, it is precipitated by digitonin, but shows no selective absorption in the ultra violet It cannot be converted into vitamin D by irradiation (*ibid*, p 980)

International Congress of Archæology and Anthropology, Portugal, 1930

READERS of NATURE will have in mind the recent criticisms of the international standing of the congresses in archæology and anthropology which have been held since the War under the auspices of the Institut International d'Anthropologie of Paris These were summarised in the leading article in our issue of Mar 1 In the recently issued announcement of the Congress to be held in Portugal on Sept 21–30 next, it would now appear that the promoters hope to meet objections which have been raised on the ground that the Congress is not truly international in character by indicating that this congress will be a continuation of the older series of the International Congresses in Anthropology and Prehistoric Archæology, of which the last was held at Geneva in 1912 The invitation is issued jointly by the Conseil permanent du Congrès International d'Anthropologie et d'Archéologie Préhistorique and the Institut International d'Anthropologie It is announced as the "xv[e] Congrès International d'Anthropologie et d'Archéologie Préhistorique" and the "iv[e] Session de l'Institut International d'Anthropologie", finally, it is pointed out that the meeting coincides with the fiftieth anniversary of the Congress held in Lisbon in 1880

While welcoming with all good will this expression of the desire of the members of the Institut that the congress should be regarded as truly international, it must be pointed out that it is not sufficient to call it so, or even to announce that it is a continuation of a former congress which has not met for eighteen years The only international element in the organisation is the committee in charge of the preparation of the scientific proceedings, which, it is understood, has no executive power and on which Great Britain is not represented The committees responsible for local arrangements at Coimbra and Oporto naturally are entirely local, but the publications committee is French with two exceptions The real executive of the Congress, we presume, is constituted as before The invitation is issued from the Siège Social of the Institut, namely, the École d'Anthropologie, and not from Lisbon

Of the "Conseil permanent" of the older Congress, M Marcellin Boule is a member of the Comité d'Honneur, and M Pittard represents Switzerland on the committee in charge of the preparation of the scientific proceedings

The Congress will be divided into sections, of which the first will deal with questions of morphological anthropology and functional ethnology, among the points specifically mentioned in this division being the methods of anthropology and especially the interpretation of statistics, the human brain from the racial point of view, endocrinology and human morphology, and the relation between the yellow races of Africa (Bushman) and the yellow races of Asia

The second section will deal with human palæontology and prehistoric archæology, in which the question of the Kitchen midden people of Portugal, Armorica, and Denmark will be discussed Another subject will be the distribution of cereals in neolithic times as well as the origin of domestic animals, particularly the dog

The third section will deal with heredity, eugenics and cognate subjects, including criminology and psycho sociology

The fourth section is of a comprehensive character, covering ethnography, folklore, linguistics, religions, and human geography One topic of discussion specifically mentioned is the geographical and ethnic origin of the Aurignacians Primitive survivals among civilised peoples should give rise to lively discussion

The session will be formally declared open by His Excellency the Minister of Public Instruction, Prof Gustavo C Ramos, on Sept 21, at Coimbra, and a dinner will be given by the Rector of the University on the same day On the following days, after the work of the sections has closed, conversaziones or illustrated lectures will be given in the evening On Sept 26 an archæological excursion will be made to Figueira da Foz on the way to Oporto On Sept 26 the Congress reopens at Oporto, on the evening of which day there will be a folk-lore fête at the Palais du Cristal, and on Sept 27 the Congress will be formally declared closed, a banquet being held afterwards On Sunday a motor expedition of archæological interest will be made to Guimaraes and Citania de Briteiros The Congress will arrive at Lisbon on Monday, Sept 29, at midday A formal reception will be held by His Excellency General Carmona, President of the Portuguese Republic, and the following and final day will be spent in visits to museums and other places of interest

Intimation of intention of attending the Congress and subscriptions should be addressed to le Trésorier de l'Institut International, 15 rue de l'École de Médecine, Paris (6[e])

Lime Requirement of Soil

A SURVEY of the results from liming experiments in progress during the last twenty five years at the Tennessee Agricultural Station was given by Prof C A Mooers in his address as vice president of Section O (Agriculture) of the American Association for the Advancement of Science at the recent Des Moines meeting, and has now appeared in *Science*, vol 71, p 81 The investigations have been carried out in the laboratory in conjunction with open air lysimeters of two types, one containing surface soil only, the other having in addition an under layer of heavy loam subsoil

One of the early discoveries was the fact that silica readily combined with carbonate of lime with the formation of calcium silicate, a form of calcium more suitable for clovers than the carbonate The idea that lime exerts a 'burning' effect on soil humus has been refuted, neither calcium oxide nor hydroxide producing increased oxidation until their conversion into carbonate or silicate, and even then the increase was temporary only As regards base exchange, the generally accepted view that potash is liberated by liming is shown to be erroneous, a normal application of lime actually repressing the leaching of this element

Concerning the relationship between calcium and magnesium, new light has been thrown on many of the older studies Liming with burnt lime or high calcic limestone was found to increase the calcium and depress the magnesium outgo, whereas additions of magnesium had the reverse effect Treatment with a calcium magnesium compound such as dolomite had the same result as the addition of magnesium only, these findings explaining the harmful action of high calcic limes on a magnesium loving plant such as tobacco

The question of the effect of liming on the oxidation of soil sulphur and nitrogen is also discussed, and the availability of added lime shown to decrease with time The chief discovery made at the station, however, is the formation of ternary systems such as $CaO \, Al_2O_3 \, CaSO_4$ by the action of aqueous solutions of calcium hydroxide and sulphate on aluminium complexes Such systems are of low solubility when alkaline, but readily soluble in neutral or acid media The reaction can be used to determine the reactive amount of alumina and silica, and is promising as a method for measuring the colloidal properties of a soil It has already proved invaluable in affording an explanation of the disintegration of concrete under certain conditions which can now be avoided

In conclusion, Prof Mooers emphasises the importance of lysimeter experiments for both the chemist and plant physiologist

Prickly-Pear Control in Australia [1]

THE attempt that is being made to control the prickly pear menace in Australia by biological means is a practical experiment of great interest and importance The initiation and progress of this work has already been referred to in the columns of NATURE, and the most recent report on the subject has lately come to hand

Since the year 1925, the measures taken to combat the scourge have greatly reduced, if not entirely arrested, its yearly spread to uninfested territory The policy of the Prickly Pear Board has been to introduce and acclimatise insects inimical to the growth of all the naturalised species of this plant In carrying out this scheme, the natural enemies of prickly pear in North and South America have been continuously investigated since 1920, and a number of species introduced, under adequate safeguards, into Australia The cochineal insect, *Dactylopius tomentosus*, is now so widely diffused that there is scarcely an area of prickly pear in Queensland or New South Wales which is not infested by this insect The plant sucking bug, *Chelinidia tabulata*, has multiplied and spread in enormous numbers, and the red spider, *Tetranychus opuntiæ*, gives every promise of soon extending throughout the length and breadth of the prickly pear area The moth *Cactoblastis cactorum* is a more recent introduction, about 300,000,000 have been liberated since 1926, and it is believed that within two or three more years it will become general in the desired areas It is estimated that 30 000 acres of prickly pear have been destroyed by this insect in about the last twelve months

In this manner a complex of insect enemies has been established Some species have naturally proved more successful than others, and their combined efforts are already bringing about a considerable measure of control of this pest plant Its reduction is most noticeable in certain scrub areas where it once formed a barrier impenetrable to animals In the heart of the infested country it is now possible to travel for 100 miles without seeing any flourishing plants The production of fruit and new growth has become greatly diminished, fewer seedlings are able to become established, while large clumps of plants are being gradually sapped and destroyed

On present indications, it is reasonable to expect that vast areas of prickly pear will be freed within a few years Too much confidence of complete eradication is to be deprecated, as the problem has not yet been solved, but the future prospects give reasons for optimism The experiment has not yet had a long enough lease to enable an estimate to be made of the possible influence of such factors as varying or extreme fluctuations of climate, disease, and native insect parasites on one or other species in the complex that is being built up Indigenous parasites and predators have indeed turned to some of the introduced insects but, up to the present, the influence they have exerted has not appeared to be great Although such enemies need close observation being kept on their activities, there is no need for premature or undue alarm that they will materially vitiate the good results that are being achieved A D I

[1] "The Progress of the Biological Control of Prickly Pear in Australia" By Allan P Dodd 44 pp Commonwealth Prickly Pear Board, Brisbane 1929

University and Educational Intelligence

CAMBRIDGE —The Cavendish professor has announced that the first course of Scott Lectures will be given by Dr Niels Bohr at the Cavendish Laboratory at 4 45 P M on May 12, 14, and 16. The subject will be "The Principles of Atomic Theory"

OXFORD —Discussion still continues on the proposal to use the sum of £100,000 realised by the Radcliffe Trust for the establishment of an astronomical observatory in South Africa The advocacy of the scheme by Prof H H Turner is criticised by Prof Lindemann on various grounds, he doubts, for example, whether any special benefit would result to Oxford in relation to other centres of astronomical study Moreover, the climate of Oxford is not conspicuously worse than that of Greenwich, Edinburgh, or Cambridge, while even if it be allowed to be unsuitable for 'positional' astronomy, there are many other lines of astronomical and meteorological research which are in need of assistance, and could well

be pursued in Oxford in consonance with the design of the founder of the trust. To this Prof. Turner replies that the scientific activities of Oxford are not, and should not be, confined to the actual precincts of the city; that additional observatories in the southern hemisphere are really needed; and that there may be a danger of undervaluing 'positional' astronomy, which has conspicuously proved its importance, in comparison with the more recent development of astrophysics.

THE Rockefeller Medical Fellowships for the academic year 1930–31 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1. These Fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation and are awarded to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. In special circumstances the fellowships may be tenable at centres of research not in America. A fellowship held in America will have the value of not less than £350 a year for a single fellow, with extra allowance for a married fellow. Particulars are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S.W.1.

THE Salters' Institute of Industrial Chemistry is offering a limited number of fellowships for chemists of post-graduate standing, the object being to afford additional and special training at home and abroad preparatory to a career in industrial chemistry. The normal value of each fellowship is from £250 to £300. Applications must reach the Director of the Institute, Salters' Hall, St. Swithin's Lane, E.C.4, by June 2. The Institute will also, in July, allocate a limited number of grants in aid to young men and women employed in chemical works in or near London who are desirous of fitting themselves for a career in chemical industry. The latest date for the receipt of applications by the Director is June 7.

THE Ministry of Agriculture and Fisheries is offering until June 15 a number of agricultural scholarships for students who propose to take up posts as agricultural organisers, teachers, or lecturers in agriculture; also research scholarships in agricultural and veterinary science. In addition, it is prepared to receive up to May 15 applications for grants in aid of scientific investigations bearing on agriculture to be carried on in connexion with a university, university college, or other approved institution or society in England and Wales. Applications for all of the foregoing should be sent (upon forms A. 472/T.G., 900/T.G., and A. 53/T.G. respectively) to the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1.

DANIEL C. JACKLING, of San Francisco, president of the Utah Copper Company, has made provision for the establishment at the Missouri School of Mines and Metallurgy at Rolla, of which he is a graduate of the class of 1892, of the Jackling Foundation for education in the sciences and arts pertaining to the mineral industry, the purpose of the Foundation being to offer loan funds and provide scholarships and special educational features not ordinarily provided for at State schools. The Foundation may eventually total £120,000. Of this amount £20,000 is to be used as loan funds and the income from the remainder for scholarships and special educational purposes.

Historic Natural Events

May 6, 1915. Thunderstorm.—During the evening a thunderstorm of unusual violence broke over the centre of London. Between 8.30 P.M. and 10 P.M. more than two inches of rain fell over an area bounded by Piccadilly Circus, Euston Road, Shoreditch, and the Strand, the amount reaching 3.00 in. at Holborn and 3.12 in. at New River Head. Practically no rain fell south of the Thames.

May 8, 1663. Thunderstorm and Flood.—Concerning this Pepys wrote (May 15): "Strange were the effects of the late thunder and lightning about a week since at Northampton, coming with great rain, which caused extraordinary floods in a few hours, bearing away bridges, drowning horses, men, and cattle. Two men passing over a bridge on horseback, the arches before and behind them were borne away, and that left which they were upon: but however one of the horses fell over and was drowned. Stacks of faggots carried as high as a steeple, and other dreadful things; which Sir Thomas Crew showed me letters to him about from Mr. Freemantle and others, that it is very true."

May 8, 1902. Great Eruption of Mont Pelée (Martinique).—For two weeks beginning on April 25, the volcano had been active, throwing out columns of ash and steam. About 8 A.M. on May 8, a dark cloud was seen to issue from the volcano. Sweeping down the slope with great velocity, in two minutes it reached Saint Pierre, the chief city in the island. The blast was tornadic in its violence, its heat was withering, and it seems to have been charged with incandescent particles. The whole city was wrecked and, with two exceptions, all its inhabitants were killed, as a rule instantaneously, the number of dead in Sainte Pierre and its suburbs being reckoned at not less than 30,000. The area of complete destruction was a sector about 8 sq. miles in area, and as a rule its boundaries were sharply defined. There was no flow of lava and no large portion of the crater was blown away, though it is estimated that the discharge of solid matter per day was greater than that of the sediment carried down by all the rivers in the world combined. The sound of the explosion was heard at St. Kitts and St. Thomas (210 miles and 350 miles). Brilliant after-glows were observed at Honolulu, Madeira, Slough, Berlin, Bombay, and elsewhere.

May 9, 1818. Drought.—At Trevereux, near Limpsfield, Surrey, it is recorded that after a deluge of rain on May 8, no further rain fell until Sept. 5, being 17 weeks and 1 day, during which all vegetation was completely burnt up.

May 9, 1867. Shower of Hazel Nuts.—On the night of May 9, during a violent rainstorm, a remarkable shower of 'berries' fell in Dublin, on both sides of the river. They were described as having the form of a very small orange, about half an inch in diameter, black in colour, and when cut across seeming as if made of some hard dark brown wood. They fell with such force that even the police were forced to seek shelter. The 'berries' were afterwards identified as hazel nuts which had been partly fossilised in a peat bog. How they came into the air is not known.

May 9, 1877. Chilian Earthquake Sea-waves.—The epicentre of the earthquake lay about 90 miles southwest of Iquique. The sea waves were observed at different places along 2200 miles of the South American Coast. They swept across the Pacific and were recorded in New Zealand (5600 miles), New South Wales (6800 miles), and so far as Japan (8900 miles).

May 9, 1893. Early Season.—The spring and early summer of 1893 were among the earliest on record in

the British Isles "Stimulated by continued heat vegetation of all kinds was forced on rapidly, and without any check worth mentioning, into leaf and flower, and in some cases into fruit, long in advance of its usual time Even in parts of Scotland straw berries were gathered in May and new potatoes and peas ready for use" (Report on the Phenological Observations, p 127) In south west England the greater bindweed was in flower on May 9, five weeks in advance of its usual date, and even in western Scotland it was only two days later The foliage of trees was abundant and well developed, flowering trees and shrubs bloomed with extraordinary freedom In the fields and hedgerows flowers were abundant and followed each other in rapid succession, but the dry and forcing weather weakened the plants them selves and they soon faded Insects were very numer ous, and the swarms of wasps amounted to a plague The earliness of the seasons was maintained into the autumn, and the harvests began everywhere at almost unprecedented dates, but were very poor over most of England

May 9, 1919 Cloud formed by Aeroplane - During a high flight over Germany, the aviator observed that at a height of 26 000 feet a streak of cloud formed behind him This cloud attained a length of about 40 miles, then gradually spread and developed into a typical cirro cumulus cloud, about 3000 feet broad Similar phenomena were repeated on May 11 On both days the weather conditions were inclined to thunder, and it seems probable that the exhaust gases supplied condensation nuclei to the air, thus giving the necessary stimulus to cloud formation

May 10, 1879 Meteorite —During the afternoon a great meteorite fell and burst near Estherville in Iowa The largest fragment recovered weighed more than 400 pounds This is the largest meteorite in America which has been actually observed to fall

Societies and Academies

LONDON

Geological Society, Mar 26 **W Campbell Smith** A classification of some rhyolites, trachytes, and phono lites from part of Kenya Colony, with a note on some associated basaltic rocks Comparison of specimens collected on two expeditions by Prof J W Gregory in 1893 and 1919, previously described by Dr G T Prior (1903) and Miss A T Neilson (1921), supported by some new analyses has led to a revision of the nomenclature —**T N George** *Ambocœlia* Hall and certain similar British Spiriferidæ The British forms do not exhibit the features emphasised by Hall in his description of *Ambocœlia*, in particular, they differ in the surface ornament, in the cardinal process, and in the musculature of the dorsal valve Two new genera, distinguished one from the other by details of ornament and cardinal area, are therefore established for their reception, and it is proposed to create a new subfamily for the reception of *Ambocœlia* and the new genera The later portion of the paper consists of a detailed description of the British species from the Devonian, Carboniferous, and Permian systems Some of these are new

Linnean Society, April 3 —**H Lister** Observa tions on the comparative morphology of the protozoan fauna found in the paunch and reticulum of rumi nants The actual species vary with the geographical environment of the host By using suitable culture media and a specially designed microculture incubator, they have, during the present investigation, been kept alive for longer periods than hitherto The cultures have shown that the bacteria inevitably introduced with the protozoa render the medium acid, and that this proves fatal to them —**H S Holden** Some wound reactions in *Ankyropteris corrugata* The tissues of the fossil fern *Ankyropteris corrugata* show well defined wound reactions In the root these consist of irregularly disposed wedges of meristem and are confined to the cortex In the stem, wounds usually take the form of irregular cortical fissures bordered on either side by a strip of meristem In the petiole, where the wound is superficial, a pad of healing meristem is developed, but, where it is deep seated, the vascular tissues may be involved —**J M Cowan** Botanical exploration through North West Persia A brief survey of the vegetation of Iraq and North West Persia observed on a tour made on behalf of the John Innes Horticultural Institution and Kew Gardens

Optical Society, April 10 **T Smith** Charts for simple two and three thin lens problems A variety of charts can be drawn each of which furnishes complete first order information on systems con structed from two or three thin lenses —**M O Pelton** The lustre of textile fibres is due to a geometrical property of transparent cylindrical filaments with polished surfaces Some of the factors notably double refraction and diffraction which might affect lustre are discussed and a method is suggested for measuring lustre based on the high lights visible on a curved lustrous surface —**W D Wright** A re determination of the mixture curves of the spectrum The paper describes a method that has been de veloped for calculating the sensation curves and mixture curves from an average set of trichromatic coefficients and the standard luminosity curve without recourse to any further experimental data A complete table of colour mixture data is given The practical value of different methods of colori metry and the most desirable primaries for use as reference standards are briefly discussed

DUBLIN

Royal Society, April 2 —**J Joly** The application of gamma radiation to deep seated tumours The applicator operates on the principle of a pseudo focus, formed by the convergence of two inclined gamma ray beams intersecting at the tumour The beams are kept in continual rotation round a vertical axis while at the same time they are carried along a path determined by a template which has been derived from X ray exploration of the tumour The movements are controlled by clockwork, and the whole applicator, in certain cases, may be worn by the patient without serious inconvenience The γ radiation may be derived from radon tubes or radium tubes such as are used in needle radio therapy, some twenty five or thirty such tubes being packed into each radiator —**J Reilly** and **D T McSweeney** A study of the polysaccharides (Pt 2)

GENEVA

Society of Physics and Natural History, Feb 6 —**J Briquet** The number of carpels in the flowers of *Campanula* The character of the trimery and penta mery of the gynæcium plays an important part in the systematics of this genus Now the author has observed that both these arrangements occur in the flowers of *Campanula Medium* It is therefore neces sary to review carefully the behaviour of various species and to modify the diagnoses and analytical tests —**J Briquet** The carpology of the genus *Mantisalca* Cass The author's studies have proved that the genus *Mantisalca* has been erroneously joined to the genus *Centaurea* —**E Briner, J P Lugrin,** and **R Monnier** The action of nitrogen peroxide and of

sulphur dioxide on lime, calcium carbonate and calcium phosphate The study of these reactions has been undertaken methodically with the aid of the technique utilised in the laboratory for work on gases, and it has led to the proof of the attack, in the absence of water, of calcium carbonate by nitrogen peroxide and by sulphur dioxide The reactions differ from those taking place in the presence of water —**L Duparc** and **L Galopin** The phenocrystals and microlites of the plagioclases of the Abyssinian basalts The authors have recognised six types of rocks, aphyric, porphyric felspar, augitic, porphyric, doleritic or ophitic, and finally a tokeite type In the porphyric types the microlites of the mass are more acid than the pheno crystals A difference in the same direction but to a less extent exists also in the augitic and ophitic types —**L Duparc** and **Ch Wakker** The auriferous layers of St Yrieix The authors have studied several deposits of the region now being worked Nearly everywhere traces of workings are found dating from the Roman occupation The auriferous quartz is always found associated with granulites and pegmatites traversing and penetrating the schists At Chom the auriferous quartz forms veins of variable thickness reaching sometimes two to three metres It is also in the form of auriferous quartz veins that it is found at Champvert, la Tournerie, and la Fagassière —**G Ladame** The metalliferous deposits of Mt Chemin, Valais The author distinguishes three groups of deposits, (1) magnetite, (2) marbles (3) fluorspar and galena The magnetite appears to have been worked from the time of the Roman occupation Its mode of formation cannot be specified On the other hand, tho fluorspar and the galena are clearly in veins

Rome

Royal National Academy of the Lincei, Dec 15 —**S Franchi** The Franco Italian border between the Colle del Piccolo S Bernardo and the Colle della Seigne, to the south of Mont Blanc —**E Raimondi** The geodetic curvature on a surface, and Liouville's formula —**L Laboccetta** General method for the construction of Fourier's 'separate functions' and of De La Vallée Poussin's 'characteristic functions' —**G Mazzone-Sangiorgi** The first elements of a new general theory for the motion of waters and other fluids (2) Seven different cases of jets are considered, the results obtained in each instance being in complete accord with those derived from the author's theory —**A de Mira Fernandes** Odographic systems —**A Tonolo** Integration of the Maxwell Hertz electro magnetic equations The author's method of integration, published in 1910, is extended to the more general form of the Maxwell Hertz equations of the electrodynamics of bodies at rest The resulting formulæ, although complex, are simpler than those obtained by Tedone in 1916 —**M Lecat** Relations between the behaviour of a binary system on distillation and the course of the temperature-vapour pressure curves of the components The conditions for determining if any particular binary system is or is not azeotropic are considered —**Remo de Fazi** and **F Monforte** New reaction of aldehydes (4) Acenaphthene and cyclic aldehydes do not form condensation products, although, in presence of concentrated sulphuric acid, they give a characteristic colour reaction If the acenaphthene is converted into acenaphthenone, this condenses with cyclic aldehydes to products which also give the colour reaction general for these aldehydes Guglialmelli and Delmon's view that the coloration is due to condensation products of fluorene is not in accordance with the experimental results —**A Cavinato** New investigations on euclase Euclase from Valle Aurina Analysis of this euclase gives results in agreement with the molecular ratios, SiO_2 R_2O_3 RO H_2O =1 98 1 2 1, and, if constituents present in small proportions are neglected, the formula becomes $HBeAlSiO_5$ Thus the accepted formula, based on Damour's analysis, is confirmed, and that given by Rammelsberg disproved —**Giulia Martinez** Basalt from Cucchiara Zeppara near Guspini (Sardinia) —**G Pupilli** Periodic respiration caused by sympathicotomy —**S Ranzi** Experimental embryology of the cyclostomes —**P Pasquini** Nervous relations of the transplanted eye and olfactory organ in axolotl embryos —**G Pollacci** and **Maria Bergamaschi** Demonstration, by means of dimethylhydroresorcinol, of the formation of formaldehyde in living plants during chlorophyllic photosynthesis Experiments made with water plants in presence of dimethyl dihydroresorcinol ('dimedon') demonstrate the formation of formaldehyde when the conditions necessary for chlorophyllic synthesis, namely, presence of carbon dioxide and chlorophyll and action of light, are fulfilled The dimedon has a narcotic effect on the plants, but does not kill them, since after the experiment the plants are still capable of assimilation —**R Savelli** and **N Soster** Apogamocarpy in *Cucurbita pepo* and *Cucurbita moschata* —**L S Da Rios** Suction fans and rings

Vienna

Academy of Sciences, Jan 23 —**K Morsch** The action of chloral hydrate and hydroxylamine on the isomeric phenylene diamines —**F Holzl**, **R Kugerl**, and **K Rokitansky** The mobility of some ions containing iron (1) Comparison of simple and complex iron salts —**G T Whyburn** (1) Derived continua dividing the plane —(2) A theorem on derived continua of the plane connected in detail —(3) Connected quantities completely dissectible —(4) Undivided elemental quantities from connected point quantities —**L Kober** The distribution of masses on the earth s surface The ratio of the surfaces of continents to oceans is about 1 to 2½ The ratio of the densities of land to sea is about 2½ to 1 Surface and density of continents and oceans are reciprocally proportional Assuming heights of continents equal to depths of oceans, then the weight of the continents is equal to the weight of the oceans —**F Machatschek** Remarks on the question of the distribution of masses on the earth's surface The ratios just quoted are changed if the continental shelf is reckoned with the continents

Jan 30 —**A Sommerfeld** The paramagnetic forces of the rare earths —**E Beutel** and **A Kutzelnigg** Contributions to analysis of luminescence (1) —**G Lock** Derivatives of phenyl ether (1) Mono nitro, amino and oxy derivatives —**K Beaucourt** Constituents of resin (2) Dehydrogenation of boswellinic acid By the action of selenium or palladium on incense resin, a mixture of aromatic hydrocarbons is produced —**T Pintner** *Tetrarhynchus* from Pacific Grove, Cal, U S A —**H Hornich** The characteristics of connexion *im grossen* and *im kleinen* —**A Rollett** and **O Schneider** Resins and resinous substances (7) Tolubalsam —**F Morton** Report on a botanical expedition to Guatemala, 1928–29

Feb 6 —**R Janoschek** Strata sequence and stratification of the Miocene of Ritzing Burgenland —**O Kühn** The Danic stage in the Alps and Carpathians —**L Waagen** The geological structure of the Eichkogel near Rein, not far from Graz —**O Gugenberger** The Cardita strata in Middle Carinthia and their fauna (1) Brachiopoda

Feb 13 —**K Menger** The introduction of complex numbers into general metrics —**P Gross** and **K Schwarz** Salting out —**K Federhofer** Kinetostatics of systems moving on surfaces

Diary of Societies

FRIDAY, MAY 2

ROYAL SOCIETY OF MEDICINE (Otology Section) (Annual General Meeting) at 10 30 A M —Papers by Prof M Sourdille and G J Jenkins

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion) at 4 30 —The Earth s Bodily Tide Dr J Proudman Dr H Jeffreys and J C Dobbie Chairman, Prof L N G Filon

ROYAL SOCIETY OF MEDICINE (Laryngology Section) at 5 —Annual General Meeting

ROYAL SANITARY INSTITUTE (at Town Hall, Tunbridge Wells), at 5 30 —Dr F C Linton and others Discussion on The Maternity Home as a Health Asset —H T Taylor and others Discussion on Can the Slum be Abolished?

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7 —C W Marshall The Metering Arrangements for the Grid Transmission System in Great Britain (Lecture).

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 —Major A W Farrer Empire Free Trade and the Engineer

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group) at 7 —Informal Meeting

GEOLOGISTS ASSOCIATION (at University College), at 7 30 —A A Millar and J S Turner The Lower Carboniferous Succession along the Dent Fault and the Yoredale Beds of the Shap District —R G S Hudson The Carboniferous of the Craven Reef Belt The Namurian Unconformity at Scaleber, Nr Settle

FARADAY SOCIETY (at Chemical Society), at 8 —Prof G Wiegner On Coagulation (Lecture).

PHILOLOGICAL SOCIETY (at University College), at 8 — Anniversary Meeting

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section) (Annual General Meeting), at 8 30 —Dr R J Clausen Ethylene Anæsthesia.

ROYAL INSTITUTION OF GREAT BRITAIN at 9 — H E Wimperis A Study of the Phenomenon of Spin in Airplanes

MONDAY, MAY 5

ROYAL SOCIETY, EDINBURGH at 4 30 —Dr R Crookall On Some Curious Fossils from the Downtonian and Lower Old Red Sandstone of Scotland —A. C Stephen Studies on the Scottish Marine Fauna. Additional Observations on the Fauna of the Sandy and Muddy Areas of the Tidal Zone —Dr E A T Nicol The Feeding Mechanism Formation of the Tube, and Physiology of Digestion in *Sabella pavonina* Dr R A Fisher The Distribution of Gene Ratios for Rare Mutations —F S Allan The General Form of the Orthogonal Polynomials for Simple Series with Proofs of their Simple Properties

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 —General Monthly Meeting

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —Sir Arthur Keith The Anatomy of Fossil Man *Homo Cardarensis* discovered in Greenland and recently described by Prof Fr C C Hansen of Copenhagen

SOCIETY OF ENGINEERS (at Geological Society), at 6 —H R. Lintern The Methods of Testing the Lubricating Values of Oils Greases etc

BRITISH PSYCHOLOGICAL SOCIETY (Joint Meeting of the Æsthetic and Education Sections) (at Bedford College), at 6 —W Platt The Child's Innate Sense of Music

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society) at 8 —Prof G T Morgan Observations on the Condensations between Formaldehyde and Aromatic Compounds

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8 30 —Major R W G Hingston The Oxford Expedition to British Guiana

TUESDAY, MAY 6

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 5 30 —Annual General Meeting

ZOOLOGICAL SOCIETY OF LONDON, at 5 30 —Dr S M Manton Notes on the Habits and Feeding Mechanisms of *Anaspides* and *Paranaspides* (Crustacea Syncarida). —Col A E Hamerton Remarks on Trypanosomiasis in Relation to Man and Beast in Africa

INSTITUTION OF CIVIL ENGINEERS, at 6 —Prof R V Southwell Aeronautical Progress, 1914-1930 (James Forrest Lecture)

IRON AND STEEL INSTITUTE (at Chamber of Commerce Birmingham) at 7 —J A. Jones Chromium Copper Structural Steels —M L Becker Carburising and Graphitising Reactions between Iron Carbon Alloys Carbon Monoxide and Carbon Dioxide —A L Norbury and E Morgan The Effect of Melting Conditions of the Microstructure and Mechanical Strength of Grey Cast Irons containing Various Amounts of Carbon and Silicon - R Whitfield Single Sheet or Thin Pack Normalising or Heat Treatment *versus* Box Annealing of Sheets.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 7 — T Austin Luminous Traffic Signals.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —J A Hall Some Problems of the Printing Process

TELEVISION SOCIETY (at University College), at 8 —R Neville-Gray Liquid Photo electric Cells (Lecture)

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8 30 — Major Trevor Great Zimbabwe

WEDNESDAY, MAY 7

ROYAL SOCIETY OF MEDICINE (History of Medicine Section) at 5 — Annual General Meeting

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Sir Arthur Keith The Anatomy of Fossil Man The Mammoth Hunters of Moravia and their Relationship to other Ancient Races of Europe

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) at 6 —P P Eckersley and N Ashbridge A Wireless Broadcasting Transmitting Station for Dual Programme Service

SOCIETY OF GLASS TECHNOLOGY (London Section) (at Holophane Ltd Elverton Street S W) at 7 30 —Discussion on The Measurement of Temperature in Furnaces

INSTITUTE OF METALS (at Institution of Mechanical Engineers) at 8 — Major F A Freeth The Influence of Technique on Research (May Lecture)

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8 —Dr L H Lampitt, E B Hughes and H S Rooke The Diastatic Activity of Honey —Dr W R Schoeller A New Method for the Separation of Titanium from Zirconium and Hafnium —E R Bolton and K A Williams The Composition and Polymerisation of Chinese Wood (Tung) Oil

ROYAL SOCIETY OF ARTS, at 8 —S K Ratcliffe National Parks

THURSDAY, MAY 8

CHEMICAL SOCIETY (at Salters Hall St. Swithin's Lane, E C 4), at 5 30 — Prof Niels Bohr Chemistry and the Quantum Theory (Faraday Lecture)

CHILD STUDY SOCIETY (Annual Meeting) (at Royal Sanitary Institute), at 6 —T J Faithfull The Re Education of the Difficult Child

BRITISH INSTITUTE OF RADIOLOGY (in Reid Knox Memorial Hall), at 6 — Prof J Murdoch The Problem of Dosage in Radium Therapy (Lecture).

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN at 7 —L D Talamon The Hypersensitisation of Colour Plates

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7 30 —F Twyman and Dr F Simeon The Wedge Sector for Quantitative Spectrum Analysis. —E T Hanson On the Diffraction of Light by a Slit —Demonstration by E F Fincham of a New Ophthalmoscope.

FRIDAY, MAY 9

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30 —Dr D Clouston The Report of the Royal Commission on Agriculture

ROYAL ASTRONOMICAL SOCIETY at 5 —Dr J S. Plaskett The High Temperature Stars (George Darwin Lecture). — Radcliffe Observatory, Oxford Positions of the New Planet from Photographs taken at the Radcliffe Observatory

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Sir Arthur Keith The Anatomy of Fossil Man The Races represented by Fossil Remains discovered by Miss Dorothy Garrod in the Caves of Palestine

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —E J Williams (*a*) The Inductance of Electromotive Forces in a Moving Liquid by a Magnetic Field, and their Application to the Investigation of the Flow of Liquids (*b*) The Motion of a Liquid in an Enclosed Space —E. Simeon The Generation of Sound by the Siren Principle —Demonstration by Dr A G Milligan of the Regional Absorption of Dyes by Crystals of Alum and Rochelle Salt

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30 —Annual General Meeting

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society) at 6

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section) (Annual General Meeting) at 6 15 —J W Moffatt and J C Emerson The Rotary Automatic Telephone System

BEDSON CLUB (Armstrong College Newcastle upon Tyne), at 6 30 —Prof J B Cohen Synthetic Drugs (Bedson Lecture)

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (Annual General Meeting) (at Criterion Restaurant Piccadilly) at 6 45 — Sir Frederic L Nathan and others Discussion on The International Abstracting and Classifying of Scientific Literature —Dr H Levinstein Chemistry House—the Present Position —H J Pooley The Jubilee Meeting of the Society

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 — Prof J Garstang, Archæology and Bible History

ROYAL SOCIETY OF MEDICINE, at 9 —Prof J Murdoch Radium Treatment of Cancer (Lecture).

SATURDAY MAY 10

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section) (at Torquay)

PHYSIOLOGICAL SOCIETY (in Physiology Department, Cambridge).

SUNDAY, MAY 11

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section) (at Torquay)

PUBLIC LECTURES

MONDAY, MAY 5

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY at 5 30 —Prof Graham Wallas Physical and Social Science (Huxley Lecture)

UNIVERSITY COLLEGE at 5 30 —Prof J Macmurray The Conception of a Personal Universe the Problem of Modern Philosophy

TUESDAY, MAY 6

GRESHAM COLLEGE, at 6 —A R Hinks The New Planet beyond Neptune (Succeeding Lectures on May 7, 8 and 9)

WEDNESDAY, MAY 7

KING'S COLLEGE, at 5 —Prof J A Gunn Pharmacological Reactions of Involuntary Muscle (Succeeding Lectures on May 8 and 9)

UNIVERSITY COLLEGE at 5 30 —Prof F J Cole The Early History of Generation and Comparative Anatomy (Succeeding Lectures on May 8, 14, 15 21 and 22)

THURSDAY, MAY 8.

INSTITUTE OF PATHOLOGY AND RESEARCH ST MARY'S HOSPITAL PADDINGTON, at 5 —Dr W E Gye The Action of Antiseptics on the Virus of Filtrable Tumours

BIRKBECK COLLEGE at 8 —Prof J Graham Kerr A Biologist on the Training of the Citizen

FRIDAY, MAY 9

BIRKBECK COLLEGE at 8 —Prof J Graham Kerr Primitive Fish and the Light they cast upon the Structure of Vertebrates

ANNUAL MEETING

MAY 1 AND 2

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers)

Friday May 2, at 10 A M —Announcement of Award of the Andrew Carnegie Research Scholarships for 1930-31 Announcement of Award of the Williams Prize to W E Simons

Dr W Rosenhain and C H M Jenkins Some Alloys for Use at High Temperatures Nickel-Chromium and Complex Iron-Nickel Chromium Alloys Part I —C H M Jenkins, H J Tapsell, C R Austin, and W P Rees Part II

J L Haughton and M L. Becker Alloys of Iron Research Part IX The Constitution of the Alloys of Iron with Silicon

M L Becker Carburising and Graphitising Reactions between Iron Carbon Alloys Carbon Monoxide, and Carbon Dioxide

A L Norbury and E Morgan The Effect of Melting Conditions on the Microstructure and Mechanical Strength of Grey Cast Irons containing Various Amounts of Carbon and Silicon

A R Page and J H Partridge The Properties of some Steels containing Chromium

D Brownlie The History of the Cementation Process of Steel Manufacture Part I —Baron de Laveleye Part II

S. Maita The Corner Ghost in Steel Ingots

CONGRESS.

MAY 19, 20, AND 21

INTERNATIONAL CONGRESS ON MALARIA (at Algiers)

SATURDAY, MAY 10, 1930

ST MARTIN'S STREET, LONDON W C 2

The Yield of Coal Seams

AN important paper on the yield of coal seams was read by Messrs Bocking and Bailey before the South Staffordshire and Warwickshire Institute of Mining Engineers in February last, and a separate copy has just reached us The main object of the paper appears to be to point out that the generally adopted basis of calculation of the yield of coal seams, namely, 1200 tons per foot thickness per acre (or, as it is often put, 100 tons per inch thickness per acre), is too low and that it would be safe to substitute a higher figure The authors explain that by the thickness of a coal seam they mean not the true thickness as measured between roof and floor at right angles to the seam itself, but the vertical thickness of the coal seam This method of calculation is of course quite sound and has the advantage that the dip of the coal seam need not enter into the calculation The generally accepted figure is one that has been used for a very long time, among the interesting manuscripts in the library of the North of England Institute of Mining and Mechanical Engineers, one of the most interesting is the journal of John Watson, a local mining engineer of considerable reputation and eminence in the latter part of the eighteenth century This journal contains the following entry under date of July 19, 1746

"An Acre of Coal or the Coal that lies under An Acre of Land in a Six foot Seam will Produce 143 Tens of Coal at 22 Waggons to a Ten and 19 Bolls to a Waggon and 36 Gallons to a Boll according to the best computation"

Apparently a 'ten' of coal varied somewhat in weight, but was about 50 tons, so that the above quoted figures come out at about 1200 tons per foot per acre, and apparently mining engineers have been content to use this ancient figure without inquiring too closely whether it applies to present-day conditions or not There is, however, an important point which has not been brought out either in the above paper or the interesting discussion that followed it, namely, as to what precisely is meant by the yield per acre The authors and all the speakers who took part in the discussion appear to have taken this phrase to mean the amount of coal got from an acre actually worked out The other sense, in which the above phrase is more generally employed, is as a basis for the calculation of the amount of coal that may be expected from an estate of a given acreage, underlain by coal seams of a given total vertical thickness, before mining operations have commenced on

the estate in question In other words, the estimate of 100 tons per inch per acre refers to the amount of coal that can be expected to be produced by an estate of given size, making due allowance for all possible faults, dykes, and 'wants' of any kind due to geological conditions as well as for the coal necessarily left behind in pillars, barriers, etc It must also be remembered that this estimate apparently originated in the Great Northern Coal field where bord and pillar working is customary and where it is not unusual for 'stooks' of coal to be left behind surrounded by goaf, which are usually too badly crushed to be worth getting Furthermore, this calculation also makes allowance for the shaft pillars, that is, for the coal left to support the shafts and the buildings and machinery round about the shafts, theoretically, all the coal in these pillars should be won before the colliery is finally abandoned, but it often happens that a good deal of it is too badly crushed to be worth winning when the time for getting it ultimately arrives

Messrs Bocking and Bailey point out quite correctly that the real amount of coal contained in a coal seam is of the order of 1500 to 1600 tons per foot per acre, and quote examples to show that such amounts have repeatedly been won by the getting of a definite area of coal Obviously, this statement, which is undoubtedly perfectly true and is amply proved by the evidence which the authors bring forward, is not necessarily in contradiction with the above named preliminary estimate, as the latter would only mean that the mining engineer in making his calculation makes an allowance of 20 25 per cent of the total coal that might be present, which he expects either to lose in the course of mining operations or not to find at all owing to the natural causes above indicated Probably the authors are right in suggesting that such an estimate errs on the side of caution, but most mining engineers will plead that it is well to be on the safe side in drawing up preliminary estimates when there are so many unknown factors, the majority of which will tend to diminish rather than to increase the quantity of coal that a given area will actually yield It may, however, be fairly conceded that the suggestion that under present day practice, where the geological features of the coalfields are so much better known than they were, and where modern methods of working restrict far more severely the waste of coal that used to obtain in the past, the percentage allowed is too high and that it might be reduced with advantage

As to the view that mining engineers working a coal seam should do their utmost to get the maximum possible yield from that seam, no mining engineer will dissent from it, and in fact this may be said to be the invariable practice to day, only qualified by the consideration that the working of a colliery is an economic proposition, and that as soon as the extraction of the last portions of a coal seam cost more than the coal thus saved is worth, it is sound practice not to attempt to save it, but to stop the operations at the most economic point It may be urged that such a practice represents a definite loss of national resources, and this is undoubtedly true except from the point of view that coal which costs more to market than it will fetch in the market is a national liability and not a national asset

A Text-book of Medical Entomology

Insects, Ticks, Mites, and Venomous Animals of Medical and Veterinary Importance Part 1 *Medical* By Prof Walter Scott Patton and Dr Alwen M Evans Pp x + 785 + 61 plates (Liverpool Department of Entomology, Liverpool School of Tropical Medicine, 1929) 20s

SOME realisation of the importance which entomology has assumed in the service of modern medicine will be obtained by scanning the pages of this up to date book, the joint authors of which have each in their respective fields gained considerable reputations as medical entomologists This is the first of four volumes which, when all have been published, will cover the field of entomology in its bearing upon human medicine, public health, tropical hygiene, and veterinary medicine It has been prepared to meet the needs of medical graduates qualifying for the diploma in tropical medicine at Liverpool

A striking feature is the departure from the idea of a conventional scientific text book, for the usual chapter subdivisions there has been substituted an arrangement of the subject into twenty eight lecture meetings, each of which occupies approximately one hour and is followed by one hour's instruction in the laboratory, where the student examines a series of prepared demonstration specimens illustrating the lecture The book is really an exposition of a method of teaching which, unfortunately, has entirely missed the viewpoint of the non Liverpool student, and it will not be an easy matter for the latter to interpret the sketchy, synoptic lecture notes, that require amplification in the actual lecture The following example taken

from the synopsis of lecture 6 on p 276 dealing with the *Aëdes* group of mosquitoes will serve to illustrate the difficulties the average reader encounters

"Important species —*Stegomyia fasciata* (*calopus*, *argenteus*, *ægypti*) Distinguishing characters Bionomics Domesticity Feeding habits Breeding places, typical and atypical Importance of resistance of egg to desiccation Duration of early stages Length of life of ♀ Distribution, *see* map I Relation to Disease, *see* notes on Lecture 4 *S albopicta* (*scutellaris*) Distinguishing characters Bionomics Breeding places Distribution, *see* notes on specimen 200 Relation to Disease, *see* notes on Lecture 20"

Specimen 200 referred to in the quotation is one of 558, which are examined by the student in the course of his laboratory practice of twenty eight hours This works out at three minutes per specimen, which seems barely sufficient for the beginning student faced with a mass of new detail and an unfamiliar terminology As the book has been largely written around these demonstration specimens, the result has been to restrict its usefulness to the Liverpool student

An analysis of the contents shows that the initial 180 pages are devoted to minute structural anatomy Here the authors have made extensive use of the technique of double embedding in celloidin and paraffin for the sectioning of densely chitinised structures such as insect mouth parts, which are not readily cut by the single embedding method They have thus been able to demonstrate clearly the exact relations to each other of the intricate piercing parts of many of the smaller blood sucking species Strict attention to morphological detail is, indeed, the keynote of the whole work, and the representation of the mouth parts of a female *Ceratophyllus fasciatus* in Fig 275, p 514, reflects the accuracy of the authors' methods in preparing minute objects for microscopic study On the other hand, the reader will find that the physiological aspects of entomology have been overlooked, and that little consideration is given to the insect as a living organism capable of responding to changes in its ecological conditions This neglect of physiology is regrettable when one remembers that the whole superstructure of the control of insect pests rests on our knowledge of their habits and behaviour Nevertheless, it must not be forgotten that it is only by careful anatomical studies that the presence of the larvæ of heteroxenous helminthes in insects can be revealed Thus a reawakening of interest in the study of internal insect anatomy might lead indirectly to a much desired extension of our knowledge of this important group of helminthes Incidentally, there is here an opportunity for valuable co operation between the entomologist and helminthologist, which up to the present has been largely neglected

The remainder of the book is devoted to the blood sucking Nematocera (180 pages), for which the junior author is mainly responsible, Brachycera (104 pages), Cyclorrhapha (178 pages), Siphonaptera (47 pages), Anopleura (60 pages), Acarina (89 pages), and venomous animals (16 pages) The penultimate lecture deals with the dissection of the mosquito and with routine methods of collecting, preserving, and mounting insects (29 pages) General principles of insect control and the specific control of mosquitoes and tsetse flies form the substance of the final lecture (35 pages)

Whatever criticism may be advanced against the book in other directions, very little exception will be taken to the profuse illustrations, which have achieved a high standard of excellence Anything finer than the wash drawings of Mrs Patton and Mr Terzi could not be readily imagined, whilst the line drawings of the junior author, Dr Evans, are notable because of their meticulously careful workmanship The photographic reproductions contributed by Miss Brown could scarcely be surpassed, and Plate XXIII, representing the mature larva of *Gasterophilus intestinalis*, is a typical example of the wealth of detail that her technique can produce In the circumstances, it is unfortunate that the arrangement of the plates in reference to the text should appear to be haphazard Plate XXIII, for example, is to be found facing p 278 in the section of the book which deals with mosquitoes, whilst the Gasterophilinæ are discussed on pp 327, 336 341, and 466 467 Further, it is curious to find that no description of the mature larva of *G intestinalis* has been furnished, and no reference to the plate is made in the text Despite the space, too, devoted to the sub family, the reader is advised in the summary of Lecture 8, p 341, that "medical officers are not expected to recognise any stage of the Gasterophilinæ"

Attention must be directed to one or two liberties that have been taken with the classification of the Diptera It is generally recognised that changes have to be made in existing schemes of classification when advancing knowledge has revealed new facts of phylogeny All such changes must, of course, be supported by sound reasons Bearing this in mind, the summary elimination by the authors of the section Aschiza of the Cyclorrhapha cannot be

defended merely on the pretext that it is difficult for the teacher to demonstrate the presence or absence of the ptilinal suture "with a pocket lens magnifying 10 diameters" The question then arises as to the position of the Syrphidæ, a family which is of minor medical importance, because of the occasional recorded occurrence of the rat tailed maggot in the human intestine This difficulty has been evaded by the degradation of the family to the rank of a sub family Syrphinæ, which is then included with others in the family Muscidæ Calypteratæ Again, the family Œstridæ has been relegated to the scrap heap and replaced by four new sub families, Gasterophilinæ, Œstrinæ, Hypodermatinæ, and Cutiterebrinæ, which are added to the Muscidæ Calypteratæ We are not enlightened as to the authors' reasons for this treatment of the Œstridæ, good as they may be Finally, the sub order Pupipara has been rejected and its component genera elevated to sub families In the illustrated synoptic table at the end of the book we find one of them, the Hippoboscinæ, included under the Muscidæ Calypteratæ, which has become a rather unwieldy assemblage It would almost seem as if the authors had fallen into the trap, which they thought to avoid The making of artificial changes in a natural group is the negation of scientific method, and where taxonomy is concerned a judicious use of the axe is recommended On the basis of our present knowledge, the Pupipara should be maintained as a separate sub order Although its association with the Glossininæ in the Muscidæ may appear to be justifiable on the grounds of similarity of mode of reproduction, the two are sufficiently divergent structurally to warrant their maintenance as separate entities

It is regrettable that a scientific text book intended for the use of post graduate medical students should contain several mis statements of fact Among others, we note on p 109 that the ovarian tubules are wrongly designated ovarian follicles The larvæ of *Wuchereria bancrofti* (p 199), *Loa loa* (p 296), *Habronema muscæ*, and *H megastoma* in their respective, intermediate, insect hosts are erroneously referred to as embryos *Ctenocephalus* (p 527) is said to have "eight, rarely seven, genal combs", whereas species of this genus have but a single genal comb composed of seven or eight spines Typographical errors are fairly numerous both in the text and in the index In the latter, we note on referring to leeches that the reader is recommended to see Hirudinea, only to find that no mention is made of the Hirudinea in the index!

It has been the worthy ambition of the authors to furnish a reasonably priced book, which would serve the needs of both the beginner and the medical graduate doing research work in the tropics The beginner, on one hand, is swamped by the mass of detail, whilst the research worker will find the omission of a bibliography a serious defect By the exercise of a stricter discrimination in the choice of material, the authors could have condensed the book considerably, and thereby enhanced its value The lack of a definite plan of arrangement makes it difficult for the beginner to get readily a concise, connected account of the various stages and life history of any particular, medically important species In place of this single volume combining the systematic and practical parts of the subject, the authors would have made a wider appeal by publishing a more conventional text book and, separately, a practical laboratory guide

Statistical Mechanics without Tears

Introduction to Statistical Mechanics for Students of Physics and Physical Chemistry By Prof James Rice Pp x+333 (London Constable and Co, Ltd, 1930) 18s net

ABSTRACT dynamical theory, classical or quantum mechanical, deals always in the first instance with comparatively simple systems such as planetary systems or atoms, finding even there complications sufficient to require our utmost skill to unravel Chemists and physical chemists always, physicists more often than not, and sometimes even astronomers, study large aggregates of such 'simple' systems and are then interested only in the properties which they exhibit in the mass It is the province of statistical mechanics to derive from the properties of individual 'molecular' systems the observable properties of these large aggregates As such, statistical mechanics is a key subject, of which the principles at least should be familiar to all students of these branches of science It is therefore all the more distressing that there has never before been available, at least in English, a really good, clear, really elementary book on statistical mechanics The difficulty of writing such a book for the proper audience is of course obvious

The subject requires inevitably considerable mathematics, and is apt to develop the more happily the more mathematics is allowed The problem, then, is to write a book which shall give a real account of statistical mechanics without shirking, but with the minimum of mathematics, and with

every *mathematical* process of more than ordinary difficulty carefully led up to by the discussion of simple examples For such a book we have had long to wait, but our long wait has been amply rewarded by Prof Rice, whose book now under review must be recorded both in form and execution to be as nearly as possible all that such a book should be

A student of physics or chemistry, who has mastered this book but gone no further, should at the least have gained a clear idea of the fundamental connexion between his more usual subject matter and the theories and facts of atomic physics, and of the methods by which this connexion must be further explored The majority of serious students ought to be able to master it, for it is admirably free from complications of merely mathematical technique A student who can master it with ease will find it an admirable introduction to more advanced works on statistical mechanics and (generally) the properties of matter in bulk, in which a more educated mathematical outlook is assumed in the reader The book should be widely read and pass rapidly to a second edition

In these circumstances, it seems worth while to mention certain minor features which perhaps might be altered, or at least reconsidered, with a view to improving the second edition

In the first place, it seems a pity to preserve in Chapter ix, presumably for historical reasons, the erroneous account of van der Waals's equation in which the effect of the 'clustering' of the molecules is ignored, that is, the effect of the Boltzmann distribution factor The account given is, of course, van der Waals's own account, but since it involves an incorrect working out of his own initial hypotheses about the constituent molecules, and since the correct working out is only slightly more complicated, might not the old form now be dropped? The author gives an excellent accurate account of his own in the later part of the chapter

Secondly, is it not time to jettison also once for all Planck's second quantum theory? It never was much of a theory, always plagued with an internal irreversibility which was really utterly destructive from the first, though of course not at first so appreciated Planck himself, though he would not readily abandon it, finally admitted himself beaten by the Stern-Gerlach experiment

Thirdly, some typographical trivialities It would be pleasant to have the possessive of van der Waals correctly printed, and in numbers of places *o* is wrongly printed for 0 Is there not also some confusion between the work function and the true free energy?

Fourthly, it might perhaps be argued that the specific heats of gases are rather inadequately discussed One would have liked more details about hydrogen, for example, Why not, in fact, an account of the complete and successful theory of Dennison? And why not a fairly complete account of some other gas at higher temperatures? It is a pity not to discuss the specific heat of the rigid rotator as given by what is now known to be the correct quantum mechanical formula, but to waste time discussing a partition function now of little theoretical interest

This leads one naturally on to a final more general point The weak point of the book seems to be an absence of detailed numerical comparisons between theory and experiment Specific heats and chemical constants are the natural places for such comparisons, but comparisons except in general statements are almost entirely lacking To include some such comparisons would make the book longer, for there is little if any space to be saved, to prepare them is a most unpleasant task, as the reviewer knows to his cost, but they would be very well worth while

These are small points, utterly negligible compared with the general excellence of the book, on which the author is to be most heartily congratulated R H F

Outlook of Higher Education

Education at the Crossroads By Lord Eustace Percy Pp iv + 104 (London Evans Bros, Ltd, n d) 5*s* net

LORD EUSTACE PERCY'S appointment as Minister of Education in the last government no doubt seemed to most people to have no particular significance The new Minister, however, soon evinced unusual signs of wanting to see things for himself and of both forming opinions of his own and expressing them This he did in an arresting manner, and with such an unusual avoidance of the customary rotund qualifying phrases of a cabinet-haunted Minister that there was on the part of some much fear, and on the part of others a good deal of hope, that he might end in some first-class indiscretion Now Lord Eustace has written a book, yet his adversaries (if he still has any) can scarcely rejoice, for if it is coloured by any political cast of thought, the candour, the large mindedness, and the courage exhibited in the book must surely disarm them

In about a hundred pages of clear print and in excellent English, Lord Eustace gives us a comprehensive survey of the region of education on which the greatest questions in our national system wait for solution There are six chapters dealing respectively with the universities and technical colleges, the universities and the schools—recent tendencies, the universities and the schools—a plea for a university policy, technical education, the idea of a local college, and universities and local colleges as partners In these chapters the difficulties of the present situation are set forth with extraordinary clarity and the measures are indicated which, according to the author's belief, would afford a practicable solution of these difficulties

The book is so terse (the author modestly terms it an essay), so closely packed with matters of interest, that it is difficult to proceed with a further indication of its contents and character without wholesale quotation It is perhaps most noteworthy, and also most praiseworthy, in exhibiting the author's full sense of the responsibilities of universities, both old and new, in relation to our whole educational system and national needs While frankly calling them to account, he shows a complete understanding of their rights and privileges, and he has conceived no idea of imperilling their souls by any measures of regimentation Lord Eustace addresses himself, evidently with equal first-hand knowledge, to the complex questions surrounding technical colleges, and here again he writes alike with firmness and sympathy of their failings and their future Particularly noticeable in this connexion is his proposal to bring adult education of the Workers' Educational Association type into organic relation with the institutions now called technical, and so to create a distinct all round local college

Incidentally, the author has emphatic comments to make on undue specialisation in school years and on narrowness in all regions of education He shows a real appreciation of the position of science in our national life—and more sympathy than perhaps would be expected with efforts to make science what men of that calling think it should be

In concluding this notice the reviewer would like to say that his recommendation of the book is based on the conviction that at the present day there is, and for some time to come there will be, a strong call on men of science, especially those with university responsibility, to give more time to the subject of our national education in its widest aspects Everyone admits that the times are critical, everyone says that education is of fundamental consequence, but few make any really serious study of it Uninformed educational talk is one of the more wearying of afflictions, and the *obiter dicta* of emphatic people who say this, that, or the other is the one remedy for all educational ills, are very distressing It is not said here that Lord Eustace Percy has given us a gospel, but he has with a merciful economy of words stated a most important case

At the outset he says "it is a safe rule that an ex-minister should in general refrain from writing books about the department for which he has been responsible" Whilst violating the letter he hopes that he does not violate the spirit Of this readers will, we are sure, fully acquit him, and be grateful for a temperate discussion of great questions by one who has had and may continue to have a chief responsibility in settling them

Arthur Smithells

Our Bookshelf

Dr H G Bronns Klassen und Ordnungen des Tierreichs wissenschaftlich dargestellt in Wort und Bild Band 5, Abteilung 4, Buch 3 *Tardigrada* Bearbeitet von Ernst Marcus Pp viii + 608 (Leipzig Akademische Verlagsgesellschaft m b H, 1929) 84 gold marks

This monograph is divisible into two almost equal parts, the first on structure, physiology, and ecology, and the second on systematics A brief statement of the distinguishing characters of the Tardigrada prefaces the first part The small size of these animals is sufficiently evident from the fact that in only two of the nineteen genera does the length reach 1 2 mm, and the majority of the genera contain forms less than half this length The author gives in 90 pages careful systematic descriptions, aided by excellent figures, of the external features and internal anatomy, and then proceeds in the next 30 pages to an account of the egg-laying habits and of the development based chiefly on that of the genus *Hypsibius*

The chapter on the physiology includes many interesting details of the powers which Tardigrades possess of withstanding drying and even repeated drying According to recent investigations, the Macrobiotes can remain viable in the so called barrel form, in dry air at 15° C, for six and a half years, but after eight years in this dry state they cannot be revived In the examples which had been dry for six and a half years movement was first observed about four hours after moisture had been supplied The account of encystation is also thoroughly adequate The section on ecology refers among other matters to the adaptations met with in shore-dwelling species and in those living among mosses A useful account is given of methods of collecting and examining Tardigrades, and is followed by a

short history of our knowledge of the group from the first observation of 'small water bears' by J A E Goeze in 1773

The systematic part contains clear descriptions of nineteen genera and subgenera, and of 274 species, 107 of which are regarded as doubtful The bibliography contains a list of 188 publications, and there is an excellent index The author, who is a keen investigator of the Tardigrada, has expended much thought and care on the preparation of this monograph, which maintains the high standard of the great series of which it forms a worthy part

The Immunology of Parasitic Infections By Prof William H Taliaferro (The Century Biological Series) Pp xv + 414 (New York and London The Century Co , 1929) 6 dollars

THIS book, which is dedicated to Theobald Smith, a pioneer in many fields of biological inquiry, is the first of its kind to present to the reader a collation and analysis of practically all the papers of any importance which have been written on the subject of immunity processes in protozoal, helminthic, and other non-bacterial infections Immunological inquiry in this field has been by no means barren in practical and theoretical results The demonstration of specific antibodies in the sera of persons suffering from helminth infection, hydatid disease, and schistosomiasis particularly, has greatly assisted diagnosis So also have the many allergic skin reactions capable of being elicited when extracts of protozoa, helminths, etc , are introduced into the dermis

Such applications of immunology to practical diagnosis are, however, excelled in interest by the light which these studies are likely to throw on problems of normal resistance and susceptibility to parasitic infections The antigenic constitution of the protozoal or helminthic unit is now receiving the attention it deserves, and specialists in this field will be grateful to Prof Taliaferro for his admirable survey of the relevant literature As well over a thousand papers are cited with their full titles, the work forms a most valuable book of reference J C G L

Jahrbuch des Forschungs-Instituts der Allgemeinen Elektricitats Gesellschaft Band 1 1928–1929 Pp 240 (Berlin Julius Springer, 1930)

THIS volume is the first issued by the Research Institution of the Allgemeine Elektricitats Gesellschaft It contains a wonderful record of research work in both applied and pure science of the highest class Brief historical introductions are given to the various subjects The book opens with a section on acoustics The A E G method of connecting up tone (talkie) films is first described and then the experimental groundwork on which it is based is given The line diagrams are very clear and the photographs of the apparatus are instructive The advanced mathematics of the vibrations of membranes are given and very striking examples of nodal figures are drawn

The section on electrotechnics is very brief Photographs are given of the A E G relays suitable for long-distance communication The sections on atom and electron physics record a great deal of valuable research Corpuscular waves and their application for analysing crystal structures are well described Instructive data are given about the contact potential between two similar metals Under electro-optics two useful papers on the polarisation of canal rays are given The volume finishes up with an article by C Ramsauer pointing out the importance of technical research laboratories and emphasising the connexion between prosperity and research

Annals of the Pickett-Thomson Research Laboratory Vol 5 *The Pathogenic Streptococci, their Rôle in Human and Animal Disease (continued)* Pp xi + 392 + 46 plates (London Baillière, Tindall and Cox , Baltimore, Md Williams and Wilkins Co , 1929) 42*s* net

VOL 5 of the Annals of the Pickett Thomson Research Laboratory continues the photographic register of streptococcal growths from oral, dental, tonsillar, and puerperal sources It contains 46 plates of excellent photographs and a letterpress of nearly 400 pages devoted to lengthy excerpts from a curiously unselected mass of literature on streptococci and their many activities The work fully merits the authors' own estimate of 'gigantic', but it is not science To the authors a streptococcus is known by the appearance of its colony on a particular medium, and on this basis there is little room left for variation It is difficult to see why it should be thought worth while to spend money on the production of these expensive volumes It is of some interest, perhaps, that the first two plates illustrate the alteration in the flora of the gums following the use of a proprietary tooth paste containing a streptococcal vaccine prepared by the authors

The Kinetics of Chemical Change in Gaseous Systems By C N Hinshelwood Second edition Pp vi + 266 (Oxford Clarendon Press , London Oxford University Press, 1929) 12*s* 6*d* net

IN order that the progress made in the past three years in the study of the kinetics of chemical change in gaseous systems may be adequately recorded, Mr Hinshelwood has prepared a second edition of his book For this purpose the chapters on energy of activation and on unimolecular reactions have been completely rewritten and a chapter on chain reactions has been added This new chapter contains the interesting suggestion that 'intensive drying' is efficient only in a limited range of chemical actions, which proceed either instantaneously or not at all, and that the trace of water, which makes it possible to propagate these actions, provides centres from which branching chains proceed A sharp distinction is drawn between changes of this type and reactions which proceed with stable and measurable velocities, and it is contended that observations made with one group of changes cannot logically be extended to the other

Infra-red Spectrum of Diamond by Infra-red Spectrometer and Raman Methods

From the data given by specific heat, melting-point, and photoelectric effect, Einstein, Nernst, and Linde mann have deduced that diamond should have a frequency varying according to the method of calcula tion from 7 7 to 11μ

Spectrum obtained by Infra red Spectrometer

The infra red spectrum of diamond has been examined by the spectrometer by Ångström, Julius, and Reinkober, but without obtaining a complete state ment of the bands and without any attempt to determine their relationships Reinkober reported transparency where Julius found absorption We have also found and are investigating such an abnormal dia mond as that of Reinkober For seven normal diamonds, however, we find a band system in which there are apparently three fundamental frequencies and one combination band The wave numbers (cm $^{-1}$) for these bands have the following approximate values $\nu_1 = 1246$ cm $^{-1}$ = 8 02μ, $\nu_2 = 2086$ cm $^{-1}$ = 4 8μ, $\nu_3 = 2438$ cm $^{-1}$ = 4 10μ, and $\nu_1 + \nu_2 = 3353$ cm $^{-1}$ = 2 98μ On inspecting these fre quencies, it appeared at first that ν_3 might be a first harmonic of ν_1, but further consideration makes it much more likely to be one of the fundamentals required for the structure of diamond, which as Bragg has shown contains a six sided ring analogous to the benzene ring Three directions in this ring starting from a given carbon atom correspond to the ortho, the meta, and the para linkings of the organic chemist

From the geometry of the puckered hexagonal ring of Bragg the ratios of lengths of these linkings are as follows

1 1 63 1 91

It is to be remarked that the ratios of the fre quencies given above come out as follows

1 1 67 1 96

Spectrum obtained by Raman's method

We have also subjected diamonds to radiation by the Raman method in which the line λ4358 is selected in the manner suggested by Wood and have examined the spectrum Here we find a sharp line at λ4629 nearly The difference in wave numbers between this and the originating line is 1342 cm $^{-1}$, which is just inside the farthest out band at 8μ but not in the centre of this wide band We have also observed two diffuse bands, but these require further investigation

Raman Effect in Diamond

From many points of view diamond is a crystal of supreme interest, and it is remarkable that, though more than two years have elapsed since the discovery of the Raman effect, no attempt appears to have been made so far to study the scattering of light in this substance I have found that quite a small diamond (half carat size) suffices to photograph the Raman spectrum of crystalline carbon Each of the mercury lines 4046 6 A and 4358 3 A excites a single Raman line of remarkable sharpness and intensity (Fig 1, marked with arrows), the wave number shifts are 1331 cm $^{-1}$ and 1333 cm $^{-1}$ respectively, in pleasing agreement with the wave number 1333 cm $^{-1}$ of the *Rest strahlen* frequency of diamond (Nernst and Lindemann, *Z Electro Chemie*, **17**, 822, 1911) The sharpness of the line is to be expected in view of the known perfection of the crystal, according to the ideas of Sir C V Raman (Faraday Society's Discussion, Bristol meeting) The brightness of the line is also not surprising in view of the ease with which organic substances generally give the Raman effect Experiment shows that the line is strongly polarised

The appearance of the Raman effect in diamond is specially significant in view of the fact that its crystal structure is not a molecular lattice but a continuously linked assemblage of similar atoms Other cubic crystals with a relatively simple structure, as, for example, sodium chloride, and sodium and lithium fluorides, which have been previously examined, have failed to exhibit any Raman lines Whether the difference between diamond and rock salt is due to the difference in their crystal structure, or due to the essential dissimilarity in the nature of the forces holding the atoms together in the lattice (homopolar in one case and electrostatic in the other) is a point which can only be settled by further research Reference should be made here to a recent interesting note by Clemens Schaefer (*Zeit für Physik*, **54**, 153, 1929)

Fig 1

Besides the two Raman lines, the spectrum shows also a diffuse band at 4155 A (marked with a dot), the origin of which is under investigation [The band is too faint to be visible in the reproduction of the photograph in Fig 1 —Ed Nature]

Photoelectric Recording of Daylight

In a letter in Nature of Mar 1, 1930, Dr W R G Atkins and Dr H H Poole describe an apparatus for the photoelectric recording of daylight A photo electric daylight recorder has been in existence at the National Physical Laboratory, Teddington, for two years and has been utilised there since April 1929 for almost continuous recording, and a few further remarks upon this subject may therefore be of interest

In the first place, photoelectric recording of day light was first described by James E Ives [1] in 1925 and continuous recording has, it is believed, been taking place under his supervision at the Office of Industrial Hygiene and Sanitation, United States Public Health Service, Washington, since that time Ives used a thin film barium photoelectric cell—made by T W Case—in which a complex surface of barium, oxygen, and an oxide of barium is formed on aluminium Notwithstanding the fact that the thinness of the film and its complex nature makes these cells

much more sensitive to long wave radiation than those of pure barium in bulk—in probably the same manner as that occurring in the red sensitive potassium cells described by N R Campbell[2] and in the cæsium infra red sensitive cells referred to by L R Koller,[3] it was nevertheless found necessary to cover the aperture of the cell with a brownish yellow filter in order to compensate for the excessive blue sensitivity as compared with that of the eye The cell used was a large one, 2 inches in diameter and 5 inches long, with the result that the current was sufficient to be recorded with the aid of a Leeds and Northrup re cording potentiometer

The apparatus at the National Physical Laboratory is concerned with the measurement of visual daylight excluding sunlight, since it is skylight rather than sunlight which is of importance in the natural illumina tion of buildings At present, therefore—in order to exclude sunlight all the year round—the illumination has been recorded only from the north octant of the sky, but an apparatus is being constructed whereby that from each of the four octants (N , S , E and W) will be recorded and which will include an adjustable screen to cut out the strip of the sky which forms the sun's path

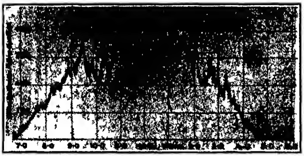

FIG 1

The measurement of illumination from definite areas of the sky involves the use of screens, the size of which governs the size of the aperture of the photo electric cell , so that the photoelectric cell used is a small one with a window only 1 inch in diameter The photoelectric current is of course also small and not large enough to operate a thread or pen and ink recorder Photographic recording is therefore em ployed

The cell used is a potassium hydride neon filled cell operated at 60 volts—or less in bright weather—and in consequence of the fact that it is used well below its glow voltage (180 v) the sensitivity remains remarkably constant A Wratten K3 filter is used in conjunction with the cell, and throughout the normal range of daylight colours this combination acts as if its colour sensitivity were identical with that of the eye

The cell is mounted on the flat roof of a high building together with the energising battery, and two long rubber insulated ignition cables lead to the recorder in a lower room Having the battery close to the cell enables the two long leads to be both at practically earth potential instead of one being at a potential about 60 v higher than the other, as would be the case if the battery were housed in the re cording room

The calibration is effected from the visual measurements made with an N P L illuminometer thrice daily (at 9 A M , noon, and 3 P M), and this method is found to be quite satisfactory

A photograph of a typical record for one day as obtained at the National Physical Laboratory is here reproduced (Fig 1)

Unless blue, violet, and near ultra violet daylight are to be recorded and the yellow and red light are to be neglected, the use of sodium cells as used by Atkins and Poole is not satisfactory, for such cells are insufficiently sensitive to red light even when used in combination with a coloured filter to reproduce the colour sensitivity of the eye The thin film potassium cells of the General Electric Company and the thin film cæsium cells of the British Thomson-Houston Company can both be used in combination with a filter to give a reproduction of the eye with regard to colour sensitivity with sufficient accuracy for daylight recording

The thread recorder, when it is possible to obtain photoelectric currents large enough to operate it, is to be preferred on grounds of economy to the photo graphic recorder

Since biologists are beginning to find it desirable to apply in their work the methods used in photo metry and in the solution of illumination problems, it would appear that the time is ripe for some degree of co operation and collaboration in these two branches of science

Effect of Hydrogen and Water on Radiation from Cyanogen-Oxygen Flame

IT is well known that hydrogen or water has a remarkable effect on the radiation from the carbon monoxide oxygen flame (Garner and Johnson, *Jour Chem Soc* , 280, 1928 , Garner and Roffey, *Jour Chem Soc* , 1123, 1929) When cyanogen is exploded with sufficient oxygen, the reaction is supposed to proceed in two steps, namely,

$$(1)\ C_2N_2 + O_2 \rightarrow 2CO + N_2$$
$$(2)\ 2CO + O_2 \rightarrow 2CO_2$$

(Dixon, *Jour Chem Soc* , 759, 1896) If this is the case, the radiation from (2) should be affected by the presence of hydrogen or water Dixon, on studying the ignition phenomena of these gases, concluded that water has no effect upon the combustion of cyanogen (*Jour Chem Soc* , 384, 1886)

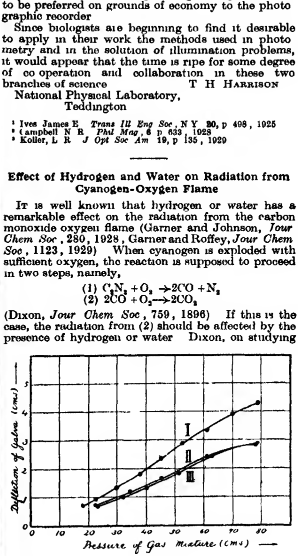

FIG 1

Recently, the total radiation from the explosion of cyanogen oxygen mixtures was measured in a bomb fitted with a quartz window (cf Garner and Tawada,

Trans Far Soc, 36; 1930), and a distinct difference between the dry and wet (that is, containing hydrogen or water) mixtures was found Curve I in Fig 1 shows the radiation from the dry mixture $C_2N_2 + 5O_2$, curve II that from a mixture containing 0 9 cm pressure of water vapour, and curve III that from a mixture containing 1 3 per cent of hydrogen It will be noted that hydrogen and water vapour have nearly the same effect, and this effect increases with increasing initial pressure The reaction velocity also appears to change with the addition of hydrogen

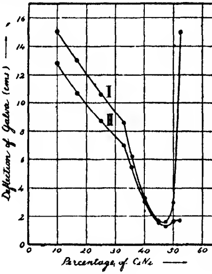

FIG 2

and water, since the explosion of the dry mixture is inaudible throughout the pressure range, whereas the explosion of the wet mixtures is distinctly audible at atmospheric pressure and may be heard even at 30 cm pressure

Fig 2 shows the variation of total radiation with different proportions of oxygen, the partial pressure of cyanogen being constant (3 75 cm) Curve I is for the dry gas, and curve II for the wet mixture (water vapour 0 8 cm) These curves also show that water vapour has an effect on the radiation emitted Its effect when more than 47 5 per cent of cyanogen is present is probably to prevent the liberation of solid carbon in the flame, and thus reduce the 'black body' emission In mixtures containing excess of oxygen, the reduction in radiation emitted is analogous to that occurring in the carbon monoxide flame

The Ions Produced by Discharges at Liquid Surfaces

IN the *Proceedings of the Royal Irish Academy*, vol 39, Section A, No 3, under the above title, J J Nolan and J G O'Keeffe give an account of experiments showing that the ions which carry the discharge from liquid points have essentially the same mobilities as those present in discharges from metal points Some statements made by these authors regarding my early work on the same subject seem to imply that it is my contention that the current in such cases is carried altogether by minute droplets of liquid I do believe this to be true under certain conditions, but not as a general rule, for positive discharges especially can be produced from liquid surfaces without the formation of any droplets, and I have shown in a later paper (*Phys Rev*, 16, p 102, 1920) than those to which reference was made by the authors named that the main characteristics of discharges from liquid points agree very closely with those obtained with metal points of the same dimensions

Two widely different conditions may exist under which masses are torn from an electrified liquid surface Large drops are pulled off by the electric field when nothing is done to counteract the pull of this field upon the surface On the other hand, if this pull due to the field is neutralised by reduction of pressure inside of a droplet a condition of surface instability (see J Zeleny *Proc Camb Phil Soc*, 18, p 71, 1915 *Phys Rev*, 10, p 1, 1917) may arise during which a very fine thread of liquid is pulled out which breaks up into myriads of exceedingly small charged droplets

The manner in which this is brought about is as follows When an electrified hemispherical droplet is accidentally distorted, the place of increased curvature tends to move back to its former position owing to surface tension forces, and in addition it is acted upon by an increased electric pull in the outward direction owing to the surface density of charge being enhanced by this increase of curvature When the electric field is sufficiently great this latter effect predominates and a thread of liquid is pulled from the surface The potential at which this surface instability begins depends solely on the square root of the product of the surface tension by the radius of curvature of the surface

On the other hand, the voltage at which an electric discharge by gaseous ions begins depends on the pressure and nature of the circumambient gas as well as upon the radius of curvature of the drop For any given gas, therefore, it depends on the relative values of the surface tension and the gas pressure as to whether or not the surface instability will start at a lower voltage than the electric discharge It so happens that for a small water drop in air at atmospheric pressure the two effects are initiated at approximately the same potential Owing to the higher dielectric strength of carbonic acid, the surface of a like water droplet in this gas at atmospheric pressure becomes unstable at a much lower voltage than is required for initiating a discharge by gaseous ions, and it was found that the water surface began to lose its charge at a potential which was independent of the gas pressure over a considerable range of pressures

This behaviour is a characteristic of surface instability and not of a disruptive electric discharge For ethyl or methyl alcohol in air at atmospheric pressure, because of the much smaller values of their surface tensions, the surface instability also begins at a much lower voltage than does the electrical discharge It is in such cases alone and only for potentials near that at which surface instability begins that I believe I have proved that the electric transfer is carried solely by liquid droplets

Water as an Activator of Luminescence.

IN the course of recent investigations on luminescence, it was noticed that many white salts showed, when wet, a bright blue luminescence under stimulation with a mercury vapour lamp, through a Uviol glass screen which excludes the visible region On drying the salts completely, the luminescence dis-

appears so that it appears to be due to the presence of water The phenomenon is very widespread, being noticeable with almost any white salt It is not confined to those salts which are appreciably soluble in water, silica, for example, showing the effect to a marked degree (this possibly accounts for the blue triboluminescence seen, for example, at the heels of a runner on wet sands at night)

In most cases there is also a phosphorescence lasting for some seconds after the extinction of the exciting light The spectrum, seen in a small direct vision spectroscope, appears to consist of a broad band with its maximum in the green at about 5500 A The colour of the luminescence with various salts is always some shade of blue varying from whitish blue to Italian sky blue, suggesting a variation in the spectral distribution in different salts

This phenomenon had a special interest for me in the light of other work recently carried out on the nature of the luminescent centre It has now been established by a number of workers in this field that the luminescence of inorganic salts is due to the presence in solid solution of a trace of an activator, for example, bismuth in calcium sulphide It has been shown by me (preliminary communication to the *Proceedings of the Leeds Phil Soc*, January 1929) that the relation between the brightness of luminescence and the atomic or molecular concentration of the activator is quantitatively accounted for by the hypothesis that the luminescence is due to the existence of centres consisting of one molecule or atom of the activator associated in solid solution with a definite number of solute molecules This leads to the relation $I = A c e^{-nc}$, where c is the molecular concentration of the activator and n is the number of molecules making up the luminescent centre Thus the existence of an optimum concentration is accounted for at the concentration $c = 1/n$

This relation has now been shown to be satisfied for various activators, bismuth, tin, lead, in calcium oxide, and also for uranin in aqueous solution Thus a determination of the optimum concentration gives the size of the centre

In the case of the luminescence activated by water, it was again observed that the brightness varied with the amount of water present, passing through an optimum or a number of optima It therefore appears that this blue luminescence is due to the association of water with the solid salts to form centres of a definite composition

Preliminary measurements on lithium fluoride show that there exist in this case two optima, corresponding to the existence of centres of the composition $LiF\ H_2O$ and $LiF\ 2H_2O$ It is hoped that further quantitative work on the luminescence activated by water will throw light on the nature of the association of water with the salts which it activates

Do Glass Tubes or Rods Bend under their own Weight?

LORD RAYLEIGH, in his letter published in NATURE of Mar 1, directs attention to an experiment performed to answer the question, Do glass tubes or rods bend under their own weight? I have tried a similar experiment bearing on this subject, and the results may be of interest to readers of NATURE

The belief is current that glass tubes and rods of about 1 m length and 1 cm diameter, standing on end, will bend permanently under their own weight To test the idea a 110 cm length of glass tubing, 1 cm in diameter and 1 mm in wall thickness, was supported on horizontal supports 1 m apart The tube was loaded at the centre with a weight of 885 gm This weight was just a little short of the average weight necessary to break a number of tubes of the same diameter and wall thickness, from the same lot of tubing The percentage composition of the glass used was approximately as follows —SiO_2, 64, Na_2O, 8 5, K_2O, 5 5, PbO, 22

Young's modulus for this glass is 6400 ± 100 kgm/mm² and the tensile strength is 6 0 ± 0 5 kgm/mm² This experiment was started in March 1924 The tube selected was originally straight enough to roll on a flat surface After the lapse of six years there is a permanent deformation (with the bending weight removed) of 9 mm at the centre of the 110 cm length

Lord Rayleigh interprets the data obtained in his experiment as indicating that the permanent deformation (resulting from suspending a weight of 300 gm at the centre of a metre length of glass rod 4 9 mm in diameter, for seven years) was too small to measure In the experiment that I have described a large permanent deformation has been observed, but in this case the glass tube was stressed almost to its breaking point Both experiments lead to the same conclusion, that glass rods and tubes of mature age do not bend under their own weight

May I suggest that the common belief that laboratory tubing and cane glass will become permanently bowed if stood on end for a year or more can be explained in the light of the following consideration Until the introduction of the machine method for drawing tubing, about ten years ago, all tubing was produced by hand shops Hand produced tubing in lengths of 1 m is never perfectly straight—some of it is in fact badly bowed The individual sticks in a loose bundle of slightly bowed sticks of tubing, stood on end in the corner of a room or in a rack, will assume under the influence of vibrations and the occasional disturbances caused by withdrawing a stick from the bundle, a configuration strongly suggestive of permanent flow under gravitational force This is especially true if straight sticks enjoy first choice

The Crystal Structure of White Phosphorus

WHITE phosphorus crystallises in the cubic system Previous attempts to determine its crystal structure by X rays have not given positive results, notwithstanding its high symmetry As a matter of fact, white phosphorus at room temperature gives, by the powder method, poor photographs, showing very few weak lines

It has been also stated (H Joung, *Centralblatt f Min u Geol*, 107, 1926) that X ray researches on white phosphorus are impossible because of its transformation into the red modification by the action of X rays

We failed to observe any appreciable transformation under the action of X rays of long wave length, and have inferred that the difficulty of getting good photographs could be ascribed only to the imperfection of the crystals and to the remarkable thermal agitation of the atoms at a temperature approaching the melting point, similar to the behaviour of certain alkali metals, which give sharp interference lines only at temperatures much below their melting point

We experimented by dipping a glass capillary,

internally filled with liquid ammonia, in molten phosphorus and lifting it so as to have it coated with a thin layer of crystallised white phosphorus The capillary was then fixed in the axis of a Debye camera The temperature may be estimated at − 35° C

The photograph obtained with the K radiations of an iron anticathode shows 22 lines, which can all be arranged in the cubic system for a lattice constant of the elementary cell of 7 17 A Supposing the cell as containing 4 molecules P_4, the calculated density is 2 23, slightly greater than the data found in the literature at room temperature (values between 1 82 and 2 0)

The details of measurements and a discussion of the structure will be published elsewhere

Several authors have deduced from cooling curves that at lower temperatures (less than c − 70° C) another modification is formed, the form of which is still uncertain, since one of the authors describes it as hexagonal, and others as trimetric or monoclinic (P W Bridgmann *Jour Am Chem Soc*, **36**, 1344, 1914 D Vorländer, W Selke, and S Kreiss, *Berichte*, **58** B, 1802, 1925)

We repeated our observations, filling the capillary with liquid air The photograph obtained in such a way (at c − 170° C) shows a large number of lines which cannot be arranged in the cubic system

The dimorphism of white phosphorus is thus confirmed We cannot yet, on account of the complexity of the photographs, decide upon the symmetry of β phosphorus, but we incline to the opinion that it belongs to a system of rather low symmetry, at any rate we may conclude that it has a rather complex elementary cell Investigations are still in progress

A Diamagnetic Simple Salt of Nickel

ACCORDING to the accepted views on atomic structure, the atoms of nickel, palladium, and platinum should, in the fundamental state, show the same outer electronic structure, namely, s^2d^8, where s denotes an electron with $l=0$ and d an electron with $l=2$ Spectroscopic evidence seems to indicate that, in the case of palladium, the electronic distribution corresponding to the fundamental state is d^{10} The magnetic properties of the compounds of these elements show great dissimilarity, for example, while $NiCl_2$ is paramagnetic and has a magnetic moment of about 14-16 Weiss magnetons, both $PdCl_2$ and $PtCl_2$ are diamagnetic (Bose and Bhar, *Zeit f Physik*, Vol 48, p 716) This difference was explained by these authors on the assumption that in $NiCl_2$ the two outer s electrons of the nickel atom are transferred to the two Cl atoms giving rise to a polar molecule, while in the other two compounds the two chlorine atoms are in covalent bond with the two uncoupled d electrons in the atoms respectively of palladium, or of platinum, thus neutralising the magnetic moments of these atoms It has, however, been found that both K_2PtCl_4 and $K_2Ni(CN)_4$ are diamagnetic

The magnetic similarity of these double salts of platinum and nickel made it worth while to investigate the properties of $Ni(CN)_2$ Mr Sushovan Dutt, working in this laboratory, has made the interesting discovery that while $Ni(CN)_2,7H_2O$ is paramagnetic, and has a moment of the same order as the other divalent simple salts of nickel, this compound shows a progressive diminution of paramagnetism with dehydration, and it has been possible to obtain a salt with magnetic moment less than 2 5 Weiss magnetons The salt is very hygroscopic, and in the process of transference from the desiccator to the sealed ampoule, into which it is introduced for magnetic measurements, it shows a perceptible change of colour There seems to be no reason to doubt that on complete dehydration the compound would be found to be diamagnetic

The observed facts can be accounted for on the assumption that, in the hydrated salt, one of the s electrons of nickel is transferred to each of the (CN) groups, giving rise to polar bonds, while in the dehydrated state the two (CN) groups are attached by covalent bonds to the two uncoupled d electrons of nickel This is an interesting illustration of how the nature of the valency bond in a compound depends on its state of hydration, and of the suitability of the magnetic method for testing such bonds in compounds of paramagnetic elements I am not aware of similar observations having been made before Further investigations are proceeding

The Problem of Stellar Luminosity

THOUGH I have the very greatest respect for any thing written by my friend and teacher Prof Eddington, I cannot see that in his letter in NATURE of Mar 29 he meets my arguments

Prof Eddington quotes a sentence of mine beginning "Similar considerations show " and says that I leave this assertion unsupported The considerations in question, which are of a simple physical character, are to be found in the two paragraphs immediately following the sentence quoted These considerations have nothing to do with evolution or secular changes occurring in Nature Prof Eddington has not discussed these arguments, though they are at the very basis of my line of thought

My earlier paper in *Monthly Notices R A S* (**87**, 708, 1927), discusses a density distribution in which the sinks of energy in the outer layers of the star exactly balance the source of energy in the inner portions, so that the luminosity of this density distribution is zero

The 'Humpty Dumpty' argument shows that the uranium model possesses a stable configuration, which is all that I require But my 'cooling' argument goes considerably further than this

The problem discussed by Prof Eddington in brief is given the mass M and the relative source distribution, to find the luminosity L in the steady state The problem I discuss (suggested by the uranium model) is given the mass M and the rate of generation L, to find the source-distribution in the steady state I do this by considering a range of density distributions, choosing those compatible with the arbitrarily assigned L and M and deducing the source distribution afterwards The conditions that the outer layers shall simultaneously enclose mass M and radiate to space at the rate L impose a restriction on the possible density distributions, the restriction depending on the surface opacity In this problem L is a *datum*, it depends neither on mass, radius, nor opacity The actual stars must be a subclass of the stars thus constructed The *observed* mass luminosity correlation must depend on the intrinsic nature of the energy generating process, it is not accessible merely from steady state considerations

New Bands in the Molecular Spectrum of Hydrogen

IN the molecular spectrum of hydrogen, 3667 lines have been measured by Finkelnburg between λ4861 and λ3314, and Gale, Monk, and Lee have given a list of 3064 lines measured by them between λ3394 and λ8902 Of course, many of the lines in the two lists are common There are several hundreds of lines in the extreme ultra violet, first discovered by Lyman and later by Werner and Weizel Of this multitude of lines, only about a thousand have been classified by Richardson and his co workers, by Finkelnburg and Mecke, by Weizel, Hori, Dieke, and others Thus we still have to account for more than 75 per cent of the lines

Recently Richardson has given an account of all the levels which have so far been observed and also their interpretation according to Hund's theory of axial quantisation It appears that to account for such a large number of unclassified lines, some of the selection principles must be sacrificed, and the one that naturally suggests itself is that for the azimuthal quantum K, namely, that $\Delta K = \pm 1$ It is well known that this principle is violated even in the case of atomic spectra when a large electrostatic field is present, for example, in Koch's experiment on the production of $1P\ mP$ lines of helium, and in the recent work of Nils Ryde (*Zeits f Physik*, **59**, 836), in the production of forbidden lines corresponding to $\Delta K = \pm 2$, 0, in the spectrum of neon Since in molecule formation we have a very large electro static field coming into play, it may reasonably be expected that this principle will be completely vio lated

Working on this idea, I have been able to identify a number of bands due to otherwise forbidden transitions, for example, between the B level of Dieke and the a level of Richardson [$2p'\Sigma \leftarrow 2p\pi_a\ {}_b$] in Richardson's recent notation P, Q as well as R branches have been obtained for vibration frequencies $n = 0, 1, 2$ and $n' = 0, 1, 2$ The lines are mostly very weak It appears that a large number of lines otherwise not accounted for may be due to a similar cause

Relation of Fluidity of Liquids to Temperature

IN reference to the editorial comment in NATURE of Mar 29, may I say that my letter of Feb 3 on the subject was communicated at the same time to the *Journal of Rheology* and appeared in its January issue in this country As you have stated, I was un aware that Prof Andrade was working on the sub ject His formula $\eta = Ae^{k/T}$, where η = viscosity, is obviously identical with the one which I proposed,

$$\log \phi = -\frac{k}{T} + A,$$

where $\phi = 1/\eta$, the fluidity As pointed out in my note of Feb 15, also published in NATURE of Mar 30, both of us were actually anticipated by Señor de Guzman and Prof C Drucker It is curious that such a con siderable lapse occurred in the recognition of what certainly appears to be the most satisfactory formula relating viscosity or fluidity of liquids to temperature I was led to it myself by the work of Stewart, Katz, Prins, and others on the X ray diagrams of liquids The existence of 'partial regional orientation' of the molecules in liquids suggests a partition into non-oriented and oriented species, the latter being regarded as slightly deformed Applying the Maxwell Bolzmann equation, in the form

$$\frac{N-n}{N} = e^{\,k/T},$$

where N = total number of molecules per unit space, n = number of oriented molecules,

and assuming that the fluidity is proportional to $\frac{N-n}{N}$,

then $$\phi = Ae^{\,k/T},$$

where A and k are constants

This derivation does not cover the actual mechanism of momentum transfer in liquids, and Prof Andrade's theoretical treatment of the subject will be read with great interest

The Exit Gas from an Ammonia Discharge Tube

WHEN ammonia is passed through a discharge tube, under the same conditions as used to prepare atomic hydrogen, an active gas is obtained This active gas is reducing in character as shown by the reduction of cupric oxide and of a zinc oxide-chromium oxide catalyst Small solid particles are heated to incan descence, a phenomenon often observed with atomic hydrogen The solid ammonia condensed in the liquid air trap (1 5 m from the discharge tube) gave an intense blue green glow when the active gas passed over it

If a substance like the zinc catalyst (which is known to remove atomic hydrogen) is placed in the gas stream, the glow in the trap is not affected This must mean that the glow is not caused by atomic hydrogen, and suggests that there must be at least one other active product present

Since the ammonia is broken up into hydrogen and nitrogen, there is a possibility that the exciting agent might be active nitrogen However, if am monia is allowed to condense in the trap and active nitrogen passed over the solid, the glow is not obtained Ammonia, when passed into the stream of active nitrogen, extinguished the yellow afterglow and caused the reappearance of the green glow in the trap

These experiments seem to indicate the presence of atomic hydrogen along with a nitrogen hydrogen compound, probably NH or NH_2, in the exit gas from the ammonia discharge tube We are continuing the work in an attempt to correlate the above with the ammonia synthesis and decomposition

Light in Four Dimensional Space

WILL you kindly allow me to make a correction to my letter in NATURE of Feb 8

As dt is generally defined as the time co ordinate *after* correction for the ordinary velocity of light over the distance dx the equations are true for all cases, and it is therefore unnecessary to assume the velocity of light infinite even in flat space This and the fact that it becomes definitely a unit vector and loses the invariant character it possessed in the orthodox theory dispose of the suggestion that it might be a measure of the curvature of space Restated, the assumption made is that at any point of space the angle between a ray of light and the world line of its source is a constant

J HALCRO JOHNSTON
Orphir House, Orkney, Mar 26

Jean Baptiste Joseph Fourier, 1768–1830

WHILE the English school of physicists at the beginning of the nineteenth century was more concerned with experimental inquiries, the French physicists were rapidly extending mathematical analysis to many important physical problems. In this direction none achieved greater success than Jean Baptiste Joseph Fourier, whose "Théorie analytique de la chaleur" has long been a classic of science, and the centenary of whose death falls on May 16 of this year.

Laplace, we are told, was the son of a farm labourer; Poisson the son of a private soldier. Fourier also came from humble surroundings, his father being a tailor of Auxerre, where Fourier was born on Mar. 21, 1768. Yet Auxerre to-day claims Fourier as its most distinguished son and his statue stands in its midst. With poverty came misfortune, for Fourier was left an orphan while still a child, and the world owes something to the organist of Auxerre Cathedral, who proved a real friend to him. Next to the organist came the Bishop, through whom the boy was sent to the military school at Auxerre kept by the Benedictines of the congregation of Saint-Maur, and to the same school he returned as a teacher of mathematics after a short period of service as a novice of the abbey of Saint Benoît-sur-Loire.

As a boy, easily at the head of his class, from his youth Fourier proved a leader of men, and the Revolution found in him an ardent but prudent Republican. From that time onwards he was a man of mark, and whether as a professor in the newly founded École Polytechnique; whether as the companion of Napoleon during the Expedition to Egypt; whether as the orator chosen to give expression to the national grief at the death of Kleber and Desaix; whether as the energetic and practical prefect of the department of Isère or as the perpetual secretary of the Paris Academy of Sciences, he fully justified the good opinion of his early benefactors. Four years were spent in the École Polytechnique; three years in Egypt; thirteen years in Grenoble as prefect of Isère; and fourteen years in Paris.

Fourier's mathematical studies began in the school at Auxerre, where he was wont to steal down to the class room in the dead of night and pore over his books by the aid of candle ends secretly hoarded, and they were never again laid aside. Even when an administrator in Egypt, busily engaged with munition work for the army, or investigating the antiquities on the banks of the Nile, he found time to publish mathematical memoirs; while his great work on the theory of heat was written at Grenoble in 1812. The essay was written for a prize offered by the Academy of Sciences; it was applauded by Laplace, Lagrange, and Legendre, yet allowed to lie unpublished until 1822. His famous memoir has been described as a masterpiece of analysis, classing Fourier among the greatest mathematicians that ever lived. So early as 1835, Comte predicted that Fourier's analytical researches would be found of great use in other branches of physics, and this has proved to be true. Ohm was indebted to Fourier when searching for the law of conductivity of electricity; Kelvin used Fourier's mathematics when engaged with the Atlantic telegraph cable, and among Heaviside's papers was found a bill for a piece of music, with notes on his investigation of Fourier's work.

It was in 1816 that Fourier was first nominated for a seat in the Paris Academy of Sciences, but his election was not approved by Louis XVIII. Next year, however, the king reversed his decision, and five years later Fourier was chosen to succeed Delambre as perpetual secretary, his colleague being Cuvier. In this situation it fell to Fourier to pronounce the *éloges* on Delambre, Charles, and Herschel, for which he was given a chair in the French Academy. Widely respected, he died on May 16, 1830, and was buried in the Père La Chaise Cemetery, where lie the remains of so many of the most eminent men of science of France. His tomb is near that of Monge and also that of the Egyptologist Jean Champollion, whose youthful imagination had been stimulated by his conversations with Fourier at Grenoble.

Report of the Departmental Committee on Ethyl Petrol

THE Departmental Committee on Ethyl Petrol, the final report of which has recently been issued (H.M. Stationery Office, 1*s*. net), was appointed some two years ago, with Sir F. J. Willis as chairman, after anxiety had been expressed in Parliament and the public Press that the widespread use of motor spirit containing lead tetraethyl might form a possible source of danger to health. In the manufacture of this substance itself in the United States of America a number of deaths had occurred, and some fear was felt in Great Britain that the use of ethyl petrol, which contains approximately one part of lead tetraethyl in 650 parts of petrol, by weight, might be dangerous to the health of its users and of the public, notwithstanding that a committee appointed by the Government of the United States reported in 1926 that there were no good grounds for prohibiting the use of ethyl petrol of this composition as a motor fuel, provided that its distribution and use were controlled by proper regulations.

In July 1928 the Committee presided over by Sir Frederick Willis issued an Interim Report (H.M.S.O., 4*d*. net) after considering the experimental work carried out by the United States Government Committee and by the Ethyl Gasoline Corporation, and after hearing evidence from a number of distinguished witnesses. In this Interim Report the Committee expressed the opinion that the findings of the United States Government Committee were justified. But some of the results of the investigations carried out in

the United States, for example, the almost universal presence of lead in the urine of persons not exposed to lead risks, did not find complete acceptance in scientific circles even in the United States, and the Committee felt that these results might not prove to be true under the conditions of life in Great Britain, consequently, the Committee then reported that while it was superfluous to embark upon such an extensive investigation as had been carried out in the United States, yet it was desirable to confirm certain aspects in that work and elucidate others not covered by it Moreover, witnesses in evidence before the Committee had directed attention to possible dangers arising from the use of ethyl petrol, and the Committee drew up its programme of work with due regard to these features Possible dangers suggested by witnesses were injuries to health from the inhalation of lead tetra ethyl due to spillage, from the absorption of this substance through the skin, from the inhalation of lead dust in streets and in garages, and from the pollution of water supplies by soluble lead salts

In order to carry out its programme of investigations, the Committee acquired the services of three members of the staff of the Government Chemist, with Mr A G Francis as director of the research, for physiological work Prof W E Dixon of Cambridge gave his services, while the War Office staff at Porton co operated in carrying out the field experiments The following is a brief account of the principal sections of that programme

In the first place, the need was felt for a revision of methods in use for determining lead in traces accurately, and the method devised, which has definite advantages as regards this feature and also in saving of time, need not be described in detail, as it is published not only in the Report but also in the *Analyst* (p 725, 1929)

It was confirmed that lead is being almost uniformly excreted in the urine of subjects not exposed to lead risks, the average of 55 persons in London being 0 04 mgm lead (Pb) in a litre, a lower but still significant value being obtained from those living in country districts, while, in comparison, for 33 workers in an accumulator factory the average was 0 28 mgm in a litre In the last set of observations the quantity excreted was found by Dr R E Lane to run in line with the apparent risk of exposure and to agree with deductions from the appearance of the blood

Examination of fine settled dust in London and the surrounding country showed that it invariably contains lead in small quantities, residents in London are thus subjected to small daily doses of lead of approximately one tenth of a milligram, and this daily inhalation of lead is doubtless one of the causes, if not the main cause, of the almost universal excretion of lead in the urine of persons not exposed to a definite lead risk How far persons absorb lead from other sources seems to be a matter that would repay further investigation A systematic examination for lead in water supplies and food stuffs, particularly canned foods and beverages or condiments sold in vessels closed with metallic capsules, would probably show further cause for the presence of lead in the human system Very small quantities of lead taken in articles of food or drink are less objectionable than similar quantities of lead inspired into the lungs, because most of the lead taken into the alimentary canal is not absorbed but voided, whereas a greater absorption of lead takes place in the lungs

As fears had been expressed before the Committee that pedestrians, and particularly drivers and traffic policemen might suffer in health by breathing finely divided lead compounds derived from burning lead tetra ethyl in an engine, a very severe traffic block was simulated in a tunnel at Porton, 12 cars using ethyl petrol being employed, when the air at breathing level was examined for its content of lead At the same establishment experiments on several observers confirmed the value found in the U S A for the fraction of inhaled lead dust that is retained by the lungs (16 per cent under resting and 32 per cent under active conditions) From these two sets of observations it was possible to arrive at the value of 0 2 mgm of lead as a maximum absorption for a person exposed in close proximity to the rear of ten severe traffic blocks per hour during a 12 hours windless day As the accepted figure is 2 mgm per day for inhalation of lead to avoid chronic plumbism in the course of years, it is concluded that the risk from this cause either to traffic controllers or to pedestrians is negligible

Some witnesses having attributed risks to garage workers and to water supplies from lead containing deposits obtained in dismantling engines running on ethyl petrol, these substances were examined, but were found to be coherent in virtue of their oiliness, and not dusty With due regard, therefore, to ordinary cleanliness, it was not considered that a risk to garage workers is involved from these deposits either by inhalation or through the alimentary canal, nor on account of their insolubility was there any chance of contaminating water supplies

Although numerous experiments in the U S A had failed to show any ill effects of ethyl petrol when applied to either human skin or the skin of monkeys and other animals over long periods, the Committee resolved to follow up an observation made by Sir Robert Robertson in the Interim Report that while on evaporating isothermally ethyl petrol the first half contains no lead tetra ethyl, and a proportion distils off with the petrol in the succeeding fractions, yet the lead tetra ethyl is to some extent concentrated in the final portion As such a liquid as the last applied by Prof Dixon to the shaved skin of rabbits for 130 days gave no untoward effects, it is unlikely, keeping also in view the above mentioned experience abroad, that even garage workers whose skin is most prone to come into contact with used lubricating oil and with ethyl petrol can be regarded as being subjected to any danger

Spillage of petrol in garages formed the next series of investigations From what has been said, no ethyl petrol may be expected in the air of

garages until the ethyl petrol has been reduced to half its volume, but later, as it evaporates, it will be found in increasing quantities The extent of the concentration of lead found in the air depends on many factors, but, in practice, the four following have importance (1) the nature of the petrol with which the ethyl fluid has been mixed, (2) the quantity of ethyl petrol spilled and the frequency of spillage, (3) the surface on which the ethyl petrol is spilled, and (4) the ventilation of the garage

To determine the magnitude of the concentrations of lead tetra-ethyl likely to be found, in practice in the air of garages when ethyl petrol is spilled, conditions were chosen to represent the spillage of a single large quantity and the repeated spillage of small quantities of ethyl petrol in closed and open garages having floors made of four different materials, namely, asphalt, concrete, wood, and glazed tiles or bricks It was found that the concentration of lead tetra ethyl in the air was greatest when evaporation took place from a glazed surface and was least from asphalt Both concrete and asphalt retained lead tetra ethyl within their surfaces, thereby reducing proportionately the concentration of lead tetra ethyl in the air Increasing ventilation reduced both the concentration of lead tetra-ethyl in the air and the time during which lead tetra-ethyl was found in the air If a large quantity of ethyl petrol is spilled in an unventilated garage, significant proportions of lead tetra ethyl will be found in the air of the garage, but as the maximum proportion of lead tetra-ethyl found experimentally in the air under very severe conditions of spillage and ventilation was far below the concentration of lead tetra ethyl stated by Eldridge (United States Public Health Bulletin No 158, 1925, p 31) to be lethal for mice, the risk of danger to health appears to be small In an adequately ventilated garage, since the concentrations of lead tetra ethyl likely to be found in the air even when large quantities of ethyl petrol are spilled are less than that stated by the American investigators to have no effects on the weight, growth, or life of animals breathing it for three hours daily for several months, the risk of injury to health appears to be negligible

By far the greater risk, and one to which the Committee refers with emphasis, is that of carbon monoxide evolved in a badly ventilated garage

That the results of the work carried out by the Committee's experimental staff agree with those obtained by investigators in the United States of America is noteworthy, because the methods adopted in the two investigations were often dissimilar in principle From a consideration of all the investigations, whether carried out in America or in Great Britain, and of the evidence given by witnesses, the Committee concludes that the use of ethyl petrol of the present composition as a fuel for motor cars will not constitute a risk to the health of the general public or to that part of the population which is most exposed thereto, namely, garage workers, police officers on traffic control duty, and drivers of motor and other vehicles

Finally, the Committee does not consider that there are any reasons for prohibiting the use of ethyl petrol in Great Britain, but recommends certain precautions, such as labelling of the cans containing it, with a warning to avoid spillage and use other than as motor fuel, dyeing the liquid, and retention of a concentration of lead tetra ethyl not above its present limit

Landscape at the Royal Academy

By Dr VAUGHAN CORNISH

ONCE again, but unhappily for the last time, we see on the walls of the Royal Academy that rendering of chequered shade by which the late Mr H H La Thangue, R A, revealed the joyousness of sunlight, especially in Mediterranean lands, as in the picture "Packing Grapes" (120)

Outstanding among the studies of mountain scenery is "Cathedral Mountain from Lake O'Hara" (44), by Mr Richard Jack, R A Cliffs set with pine trees rise from still, dark waters, snow slopes, above, coldly grey, reach to the foot of the towering crag from which the mountain takes its name The deep shadowing of cyclopæan rocks harmonises with the sombre pines below The companion picture, "Lake O'Hara, Canadian Rockies" (243), in another room is carried out in the same manner, a fine interpretation of the solemnity of mountains and "the strength of the hills" "A Glen of Arran" (81), by Mr Guy Kortright, an assembly of mountain peaks strongly coloured in the full light of day, but stripped of atmosphere, is extraordinarily suggestive of silent solitude, so that the artist has been successful in his use of an extremely trying convention Mr Sydney Lee, R A, has a painting of "Sunset in the Mountains" (401), which shows huge turreted forms silhouetted in shades of deep purple against a glowing sky, one of the most deeply emotional aspects of the high mountains

Among the studies of the sea we come first to that of "Silver Moonlight St Ives Bay" (60), by Mr Julius Olsson, R A, in which a succession of long, low rollers sweep in silver foam over the shallows of a curving shore The lights of the fishing fleet, dimly discerned on the dark waters beyond, bring the human touch without impairing the elemental character of the scene, for the long shoreman is, in his occupation, still the primitive man whose work and sport are one In "Fresh Morning off the Scillies" (161), by the same painter, a study apparently made from a sailing boat, the waves, rising as high as the point of sight, produce the effect of size and power which is lost when they are overlooked from a lofty deck Thus seen, it is the sea which is the more massive element, the distant land, dimmed by the salt spray, appearing unsubstantial Mr Norman Wilkinson also pushes off in a boat, and thus gets full value from the waves in the only possible manner "A Newfoundland Fisherman" (359)

by him is a study of a companion boat, with hull rising above the line of sight, the wonderful curves of wind-filled sails cutting across a rain washed sky, the tumbling sea dark under the squall cloud hanging overhead Such pictures recall the adventure and the beauty which attend the sport of sailing, an occupation which, moreover, permits us to explore the scenery of our coasts and estuaries, which can never be fully appreciated from the land ward side alone

In "The Spey, Fochabers" (103), Mr S J Lamorna Birch shows great skill and knowledge in the treatment of the waters of a river which, within a short compass, has many varieties of motion

We cannot but deplore the scarcity of landscapes in which animal life is the focus of interest, but in Mr Arthur Wardle's "Under the African Moon" (164) we have at any rate one fine example The scene is the rocky desert, that stern landscape where man cannot live but has often gone to pray Seen in the monochromatic moonlight, the lion and lioness watching from the edge of the escarp ment are one in tone and colour with the back ground, the only contrast that of their rounded, supple forms against the rugged outlines of the rock If we had an unbiased appreciation of the beauty of living form, should we not give more attention to that of the great felines and relatively less to that of man? Granted that a man's hand is a much finer structure than the paw of a beast, yet when we examine the limbs we find a balance and rhythm in those of the lion and leopard of which biped man cannot boast

A word in conclusion on certain pictures which illustrate matters relating to that heritage of English scenery, the preservation of which, as was aptly stated in the *Times* of Friday, May 2, is becoming the subject of "a great national debate" "Midsummer Evening in Somerset" (279), by Mr Charles S Cheston, shows one of those splendid prospects of well wooded lowland which are seen from hills of no great height in southern England No native of a mountainous country looking up at these insignificant elevations would suppose it possible that they could provide such extensive views In Somerset itself we have a notable example in the low ridge of the Polden Hills, where a view-point of special interest has fortunately been secured and vested in the hands of the National Trust In "Blakeney from Cley" (766) Mr A Raine Barker has sympathetically rendered in smooth water colour a landscape of interest in relation to an important Nature reserve, which derives an old world charm from the great towers of the two village churches "Moel Siabod" (1257), a small aquatint by Miss Eveleen Buckton, gives a good impression of the wild scenery in that part of the ancient Snowdonia which, it is hoped, will soon be scheduled as a National Park

Mr Harry van der Weyden's large canvas, "From Ballard Down" (420), shows the beautiful waste of Studland Heath and a very interesting outline of coast and estuary in the mellow sunshine of late afternoon Access to this delightful bit of wild country has been lately made easy for the large resident and visiting population of Poole and Bournemouth, and this is for the moment a bene ficial event The beauty of the broad, open ex panse is, however, of a particularly vulnerable character, and its charm will vanish if it be built upon By all means let the many come and enjoy the heath, but let us hope that the corporations of Poole and Bournemouth will realise that, as Beachy Head stands to Eastbourne, so does an unspoilt Purbeck stand to their towns, an extra mural asset of financial as well as sentimental value

Obituary

PROF GEORGE A GIBSON

PROF GEORGE ALEXANDER GIBSON, whose death at Scotstounhill, Glasgow, on April 1, we greatly regret to record, was born at Greenlaw, Berwickshire, on April 19, 1858 His father, the late Mr Robert Gibson, was highly respected throughout the Greenlaw district as a leader in ecclesiastical and political affairs

Prof Gibson was educated at the local Free Church school, from which he proceeded straight to the University of Glasgow, where he won high dis tinction in classics, English literature, and philo sophy, as well as in mathematics In 1882 he gained the Euing fellowship in mathematics and natural philosophy, and in the following year he was appointed assistant to Prof William Jack, who then held the chair of mathematics During the succeeding twelve years he established his reputation as an enthusiastic and capable teacher, and was responsible for the initiation and conduct of numerous courses on advanced mathematics, which were of great service to the honours students

In 1895, Prof Gibson was appointed professor of mathematics in the Glasgow and West of Scotland Technical College, where he remained until 1909, when he returned to the University of Glasgow as successor to Prof Jack During his period at the Technical College notable developments took place in the aims and scope of the work of that institution, and in all these Prof Gibson took an outstanding share, thus earning the gratitude of his colleagues and of the governors of the College

On returning to the University, Prof Gibson took the opportunity to reorganise the mathematical teaching there, tutorial instruction was provided for all the students, and the curriculum was widened and extended After the War the number of students rose to 900, but in spite of all difficulties the high standard of the work was maintained

Prof Gibson was a great teacher who loved his work, and for whom the interests of his students were paramount He was also an eager and tireless student, with a remarkably wide and thorough knowledge of mathematical literature He became a recognised authority on certain parts of the history of mathematics, and wrote numerous papers on the origins of the calculus and on the great Scottish mathematicians He was the author

of several well known text books, the most notable being his "Elementary Treatise on tho Calculus", a standard work extensively used throughout the British Empire After his resignation in 1927 he prepared a large and important volume on advanced calculus, which is at present passing through the press Many books, written by members of his staff, have also benefited by his profound learning and long experience, always freely and generously placed at the service of younger workers In the Edinburgh Mathematical Society, which he joined soon after its foundation, Prof Gibson was a leading figure, and a frequent contributor to its publications From 1917 until 1920 he held the office of vice president of the Royal Society of Edinburgh The Universities of Edinburgh and Glasgow both conferred on him honorary LL D degrees, the former in 1905 and the latter in 1927

An enthusiastic administrator, Prof Gibson rendered important services to the cause of education in Glasgow He was one of the original members of the Glasgow Provincial Committee for the Training of Teachers, after returning to the University he became a governor of the Technical College, for a long period he acted as chairman of the governors of the Park School Company, and in the Senate and University Court his sound and forceful counsels carried great weight with his colleagues On the occasion of his retirement his friends and students combined to testify to their respect and admiration by raising a fund for the endowment of lectures on the history of mathematics, to be given at intervals in the University of Glasgow, and to be known as the George A Gibson Lectures

T M M

Dr David Draper

In September of last year David Draper, one of the oldest of South African geologists, passed away at the ripe age of eighty years He was well known throughout the land as the founder of the Geological Society of South Africa in 1895 He was born in the Cape Colony in 1849, and was the son of one of the English settlers who came out to South Africa in or about the year 1820 Most of Dr Draper's schooling was done at Colesberg in the Cape Colony, which place he left whilst still in his teens to join the small army of diggers occupied in opening up the diamond mines of Kimberley in 1868 After taking an active part in this work with a fair amount of success, he departed for the Lydenburg and Barberton Gold Fields, which he closely studied, and later settled for some years in Natal, where he made himself acquainted with the extensive coal fields of that colony The richness of the gold mines of the Witwatersrand afterwards drew Dr Draper thither, and one of his first commissions of importance was to unravel the geological section from Vereeniging to the norite 'Pyramids' north of Pretoria on behalf of the local Chamber of Mines This work, which covered an entire section of the Witwatersrand beds, was successfully accomplished and has stood substantially correct to the present day

It was about this time that Dr Draper realised the necessity of furthering the work of geologists, mining men, and prospectors in South Africa, and the result of his efforts was seen in the formation of the Geological Society of South Africa In addition to being the founder and first secretary and treasurer of this Society, it is interesting to note that he was also the first South African born fellow elected to the Geological Society of London

One of Dr Draper's first efforts for the South African Society dealt with the primary systems of South Africa, and the conglomerate beds of the Witwatersrand, which at that time were creating world wide interest on account of their unique geological features and richness as gold bearers From this time on Dr Draper was an ardent worker in the field of geology, and visited such distant parts of the world as Borneo, Asia Minor, and Brazil on special geological excursions Some of his most useful contributions relate to the diamond occurrences of South Africa and Brazil

For the valuable services rendered to the science of geology in South Africa, Dr Draper was made an honorary life member of the Geological Society of South Africa—a distinction conferred only twice on South African members during the existence of that Society In 1927 the honorary degree of doctor of science was conferred on him by the University of the Witwatersrand

The contributions to geological science by Dr Draper were numorous, and a bibliography of his works, compiled by the present writer, contains no less than fifty seven papers to scientific societies and the technical press in various parts of the world

Harold S Harger

Dr Albert von Le Coq

A dispatch from the Berlin correspondent of the *Times* which appeared in the issue of April 25 announced the death of Dr Albert von Le Coq, the famous German explorer and archæologist, at the age of sixty nine years Dr Le Coq was a native of Berlin, and for some time was director of the Museum für Völkerkunde in that city He was, however, best known for his investigations in Central Asia

In 1904 and 1905, Dr Le Coq made two expeditions of archæological exploration in the area at the foot of the eastern Tian Shan Mountains in the neighbourhood of Kurfan and Koria On one of these he was accompanied by Dr Albert Grunwedel, the well known authority on Buddhist art and archæology As a result of the excavations in the sand-buried city ruins in the area, a large number of Buddhist wall paintings and other relics were discovered and brought back to Berlin The most important discoveries, however, were a large number of documents written in a variety of alphabets on Chinese paper, vellum, and wood Not only did these reveal links between Hellenism, Persia, India, and China, but more important still it was found that a new and hitherto unknown Aryan language with two distinct dialects had been discovered Study of Tocharian, this new language, has since revealed that it differs in phonetics, vocabulary, and

structure from all other of the Asiatic Aryan languages and belongs to the western or *centum* group of Aryan

Dr Le Coq's most important book described his work in Asia under the title "Buddhistische Spätantike in Mittelasien" A semi popular and well illustrated account of the results of his excavations was published (1928) in English under the title "Buried Treasures of Chinese Turkestan" In 1906, Dr Le Coq was awarded the medal of the Order of St John of Jerusalem, struck in gold for the first time, for saving the life of Capt (now Brigadier General) J D Scherer while on a journey in Central Asia in circumstances of exceptional difficulty Dr Le Coq was an honorary fellow of the Royal Anthropological Institute of Great Britain

WE regret to announce the following deaths

Prof J Wemyss Anderson, who was John William Hughes professor of engineering refrigeration in the University of Liverpool from 1920 until he retired in 1924, aged sixty one years

Prof Mary Whiton Calkins, professor of philosophy and psychology at Wellesley College, past president of the American Psychological Association and of the American Philosophical Association, who was one of the first to establish a psychological laboratory, on Feb 27 aged sixty six years

Dr H J B Fry, pathologist to the Research Institute of the Cancer Hospital and honorary secretary of the Investigation and Scientific Advisory Committees of the British Empire Cancer Campaign, on May 5

Lieut Col H H Y Hearsey, formerly Principal Medical Officer of Nyasaland, known for his work on blackwater fever, on April 30, aged sixty three years

News and Views

THE latest *Bulletin of the Geological Society of China* (vol 8, No 3, 1929) contains three memoirs which supplement the information given in the earlier *Bulletin* (vol 8, No 1) already discussed in NATURE of Mar 22, p 448) with reference to the discovery of an almost complete brain case of *Sinanthropus* by Mr W C Pei on Dec 2, 1929 Father Teilhard de Chardin and C C Young give an account of the geographical and geological conditions at Chou Kou Tien and a summary of the evidence which goes to establish the fact that the place where the fossil remains were discovered was once a limestone cave actually occupied by Peking man at a period later than the Pliocene and earlier than the loess They suggest that the age of all the fossils is Lower Pleistocene Vast quantities of fossilised remains of animals associated with *Sinanthropus* were found The identifications of these are given in the report and the palæontological evidence for the determination of the period is set forth with great clearness

THE discoverer of the skull of *Sinanthropus*, Mr W C Pei, gives an account of an event which is perhaps the most significant, if not the most momentous, in the history of human palæontology, and Prof Davidson Black gives in print the account of the skull, which was reported (from his manuscript) in NATURE of Mar 22 His memoir, however, is illustrated with a series of nine plates giving full size photographs of some of the stages in the long and difficult task of removing the hard matrix of travertine from the skull This was successfully completed during the week when the *Bulletin* was published (two months after the reports it contains were written), and then was revealed the unexpectedly simian type of temporal bone in association with a peculiar type of parieto occipital conformation hitherto unknown in any other human skull with the solitary exception of the Piltdown skull in its correctly reconstructed form

BY the courtesy of Prof J L Myres, secretary of the Seventeenth International Congress of Orientalists, we have received a copy of correspondence with the Secretary of State for the Colonies covering a schedule of facilities to be extended to archæological expeditions in Palestine which have now been approved by the Secretary of State for the Colonies and are in force as from April 1 of the current year The facilities and privileges in question will be granted by the Palestine Government to all archæological expeditions in possession of a valid licence to excavate in Palestine in accordance with the provision of Section 9 of the Antiquities Ordinance of 1929 It will, however, be necessary as a preliminary to the grant of any facilities that the holder of a licence should produce a statement by the Director of Antiquities that the expedition has been approved by the High Commissioner for the purpose of exemption and other privileges The privileges, which are set forth in detail in the schedule together with the procedure to be followed in each case to secure their operation, are liberal and varied They have been drafted with great care and a full knowledge of the difficulties arising out of legislative and fiscal regulations which beset archæological expeditions Further, and this is even of more moment, they evince on the part of both the Palestine Government and the Colonial Office a sympathy with and interest in archæological exploration which are gratifying and encouraging to those concerned with the promotion of archæological study in the field

THE facilities granted affect both the results of archæological exploration in Palestine and the personnel of the expedition Most important under the first head is the regulation that export Customs fees will be remitted on antiquities allotted to the holder of a licence as a result of the division with the Department of Antiquities of the objects found, while import Customs duty is remitted on instruments and scientific appliances needed for the purpose of excavation and archæological study, as well as on camp and other equipment for the expedition This applies whether the articles are imported by sea, air, rail, or parcel post Reduction in railway fares is granted to all members of the expedition including half fare reduction of third class fares for labourers In the case of skilled labour imported from Egypt, however, it must be shown that suitable labour is

not available in Palestine Both archæological equipment and antiquities are entitled to a reduction of freight on the basis of one half the full rates on passenger train and according to scale on goods trains In order to minimise any difficulties which might arise under the immigration regulations, the normal procedure to obtain visas for members of the expedition and for such labourers as cannot be engaged in Palestine is to be simplified On receipt of a statement in advance by the holder of a licence, the Director of Antiquities will issue a certificate to the Chief Immigration Officer, who will thereupon issue the necessary visa authority to the consular authority concerned No remission of immigration fees will, however, be granted The simplicity of the procedure in each case should ensure the smooth working of the regulations They have been framed on such broad lines and in so friendly a spirit that expeditions in Palestine should be able to work with little, if any, of the 'red tape' difficulties which have often proved an embarrassment to archæological study in other countries

A REGULAR telephone service between London and Australia was inaugurated on April 30 At the English end the transmitting station is at Rugby and the receiving station is at Baldock, Hertfordshire The corresponding Australian stations are Pennant Hills for transmitting and La Perouse for receiving, both in the neighbourhood of Sydney The two links are combined and controlled at the London Trunk Exchange and the Sydney Telephone Exchange From these points access is obtained to the land line telephones of the two countries The path of the voice from an English subscriber to Sydney goes first to the London terminus It next goes over 85 miles of land line to Rugby, and then goes over the radio link of 11,000 miles to the station at La Perouse, seven miles from Sydney From there it goes by the land line to the Sydney terminus and thence to the listener in Australia When the Australian speaks it goes to the transmitting station at Pennant Hills, then the radio link to Baldock and back to London, which is connected to the subscriber by his telephone wire The first official conversation was between the Prime Ministers of the two countries, and was broadcast both in Great Britain, at 8 30 A M, and in Australia, and was heard very clearly About an hour later the private conversations got blurred owing to 'fading' This was attributed mainly to an atmospheric disturbance taking place in the Indian Ocean

THIS new radio link connecting Rugby and Sydney, 11,000 miles long, is much the longest in the world The length of the Buenos Aires to Madrid public telephone link is 6400 miles On April 3 a radio link 5300 miles long was opened connecting Buenos Aires to Netcong, N J, in the United States These lengths make the telephone link between England and America, 3200 miles long, comparatively short Five continents are now connected by telephone It is possible, for example, for a subscriber in Santiago, South America, to talk to anyone in Ceuta, Africa His voice would first pass over the wires crossing the Andes to Buenos Aires, then to Netcong by radio, and by wire to New York From there it would go to Rocky Point, Long Island, and by radio to Cupar, Scotland, then by wire to London and by submarine cable to Boulogne After going through Paris, Madrid, and Algeciras, it would go under the Straits of Gibralter by a submarine cable to its final destination It could also have been sent direct from Buenos Aires to Madrid It is instructive to note that the messages sent from New Jersey to the Argentine can be sent by one of three different wave lengths It has been found that although one may be badly affected by atmospherics, another may be scarcely affected at all

Now that the telephone service is so widely established, and seeing that its usefulness is continually increasing, the Post Office engineers might be excused if they regarded somewhat coldly other methods of communication Like the ancient Athenians, however, they are always seeking after some new thing The latest development is a teleprinter service for subscribers through telegraph exchanges We learn that the first exchange will be in working order about the end of the year The new service will be operated in a somewhat similar way to the telephone service When the operation is completed, two subscribers will be able to telegraph typewritten messages to one another Each subscriber will be provided with a teleprinter, the use of which can easily be mastered by a typist, and will be allotted a number By depressing a button the exchange operator is called and the required number will be dialled to him When the required connexion is made, 'thro' will be typed on the teleprinter The subscription to the exchange which is at present contemplated is of the order of £70 a year and will cover the installation and maintenance of the lines and instruments and all communications with other subscribers on the exchange Additional instruments can be hired at a cost of about £50 a year At the outset, the new service will be confined to the London area, but we expect that it will develop so as to cover many of the larger centres This innovation will make telegraphy more popular, as it will obviate the necessity of sending telegrams to a public office for dispatch The first exchange will be in the Central Telegraph Office It is hoped that subscribers will be able by this means to forward telegrams for dispatch by all telegraph companies and to receive their incoming telegrams directly on their teleprinter instruments

THE Safety in Mines Research Board has just issued Paper No 58 (London H M S O) dealing with the use of steel pit props in collieries, as usual, the publication is issued at an uneconomic price, namely, one shilling, in order that it may be as widely read as possible in the coal-mining industry The report is signed by Messrs Ashley, Dixon, and Hogan, the first named is one of H M Inspectors of Mines, who has been employed as a practical investigator on behalf of the Board, whilst Prof Dixon and Dr Hogan

are well known research workers The report points out that the value of steel arches for roadway support has been proved beyond doubt, and that steel props have been successful at the working face under a large number of conditions, it being necessary, however, that the type of prop selected should suit the particular conditions at the coal face Some thirteen different forms of steel props are here fully described, together with the results obtained with them both in actual practice and under test, and a comparison of these props with ordinary Norwegian wooden round props is also appended As regards the practical side of the question, it is shown that although the first cost of a steel prop is much higher than that of a wooden prop, the use of the former has been attended with very marked savings, which in one case is said to be as much as 9d per ton of coal compared to the cost of timber

PERHAPS the most interesting section of this report on steel pit props deals with the effect of the use of steel props on the accident rate, and the results are summed up in one sentence "Where steel props have been used in Great Britain there has been a marked freedom from reportable accidents from falls of roof" Another interesting sentence states that "At Ashington Colliery, Northumberland, very few reportable accidents have occurred where steel props are in use" It will be remembered that a few months ago the miners at Ashington were prepared to come out on strike on the ground that the steel props used by that colliery company were a source of danger, and this authoritative statement to the contrary shows how absolutely without foundation was the above contention of the miners, and sheds light upon the trivial pretexts which are at times made the basis of a proposed strike

BRIGHTLY coloured mock suns were seen from a number of places, including London, on the afternoon of May 1 last The phenomenon is not often shown with sufficient brilliance in these latitudes to be obvious to the casual observer, and were it not for the fact that at places where a regular watch has been kept for it with certain optical aids, for example, at the Radcliffe Observatory, Oxford, it is observed on a considerable number of occasions in an average year, the phenomenon would be regarded as distinctly rare outside the polar regions These mock suns showed characteristic horn like projections away from the sun along the space appropriate for the mock sun ring, and occurred in connexion with the ordinary halo of 22° radius A sun pillar was present, and an upper arc of contact—a bow of light making contact with the 22° halo, the convex side being towards the sun The ice crystals in the upper atmosphere that caused the display were due to the presence of cirrus cloud connected with a system of depressions over southern Europe, and some turret cloud (alto cumulus castellatus) was visible in London later in the day Neither form of cloud is suggestive of settled fine weather, and, in spite of the presence of a large anticyclone centred over Scotland, thunderstorms broke out in southern England within twenty four hours of the occurrence of the mock suns

IN his Friday evening discourse delivered at the Royal Institution on May 2, Mr H E Wimperis, Director of Scientific Research, Air Ministry, discussed the present state of our knowledge of the phenomenon of spin in aeroplanes The motion of an aeroplane in a circular path is just as steady and just as normal as that of straight flight Even in the most troublesome form of spin, the aeroplane cannot be charged with behaving in any but a purely normal and quite virtuous way Our efforts must therefore be directed not towards the curing of a supposed fault but at making this particular form of stable motion as controllable at the will of the pilot as any other of the machine's forms of motion With the aid of models and kinematograph films Mr Wimperis illustrated the growth of the forces which make for autorotation of the wings and so lead to the ordinary spin, and of the centrifugal forces in the various aeroplane parts which tend to raise the nose of the machine into the 'flat spinning' attitude and definitely oppose the pilot's effort to get the nose down and so resume normal straight flight A detailed study is being made of the various ways in which the pilot's controls can be so strengthened as to make him always able to overcome these autorotation and inertia forces This study is being carried out by the use of model aeroplanes which are either observed and photographed when spinning, or are held in spinning attitudes in a wind tunnel so that the forces acting upon them can be measured At the same time, full scale experiments in free flight are being undertaken so that records can be made by instruments of the nature of the motion in each of the various types of spin

AT the annual meeting of the Royal Institution held on May 1, the report of the Committee of Visitors for the year 1929 was read and adopted, and the following officers elected *President* The Duke of Northumberland, *Treasurer* Sir Robert Robertson, *Secretary* Major C E S Phillips The alterations which are being made at the Royal Institution occupy a prominent position in the report of the Committee of Visitors Plans are shown of the rebuilding now in progress, which has been undertaken at an estimated inclusive cost of £80,000 As is well known, the chief alterations have concerned the lecture theatre, the shape, size, and general aspect are being preserved so far as possible, but there will be greatly improved arrangements for entry and exit, increased comfort and additional lecture facilities, with full provision for the display of kinematograph films A range of lighted show cases is being constructed round the semicircular corridor beneath the theatre tiers for the display of some of the Institution's historical apparatus During the building operations, the principal pieces of apparatus used by Rumford, Davy, Faraday, Tyndall, and Dewar have been placed on exhibition at the Science Museum, South Kensington As the

result of a private appeal, generous donations towards the costs of reconstruction have been received from individuals, City Companies, and electrical and chemical industries which owe their existence to the scientific work carried out at the Royal Institution With the sale of the American MSS known as the Dorchester Papers, the total receipts have been nearly £49,000 It is proposed to issue a wider appeal for the remainder of the money, and also for an endowment fund for research in the Institution and the Davy Faraday Laboratory, in connexion with the celebration of the centenary of Faraday's discovery of electromagnetic induction The Faraday celebrations will begin on Sept 21, 1931, and the centenary meeting of the British Association will open in London on Sept 23

WE have already referred to the increased interest being taken in the study of natural history in China Fresh evidence of this movement is afforded by the publication of the first number of the *Hong Kong Naturalist*, a quarterly illustrated journal for Hong Kong and South China, to be devoted to the description of features of the fauna and flora of South China and neighbouring countries The first number indicates the character of the magazine—a combination of more general articles for the non expert and of more technical studies for the trained naturalist Amongst the former are instalments of accounts of the birds, orchids, and ferns of Hong Kong and, specially to be commended, a simple diagrammatic scheme indicating the months when the nests of different birds may be found The special articles include the beginning of a synopsis of the fishes of China Some experience of magazines with such a twofold aim, however, suggests the warnings that continued articles which run through endless numbers are not popular, and that for the general naturalist systematics is often a bore Biological studies, life histories, up to date summaries of modern points of view, should not be forgotten They are equally scientific, have more interest, on the whole, for the general reader, and should tend to turn the attention of local field naturalists to profitable and more congenial lines of observation Already, we understand, a gratifying demand for the new magazine has been received, and we wish it all success

IN a recent issue of *Helios*, the German electrical journal for export use, which is printed in German, French, and English in parallel columns, there is an interesting article by E Schwandt on automatic signalling for railway level crossings The railway track for a distance of 300 yards on each side of the level crossing is insulated When the train is on the insulated portion of the track, a local circuit is completed and the white lights from the lamps at the gates on both sides of the crossing being automatically screened show red When the last carriage leaves the insulated track, the lamps give white light For greater safety, instead of having a steady red light, intermittent flashes of white and red light can be given, the white flashes lasting longer than the red ones The Berlin Municipal Railway has already adopted this method The German Automobile Club has also taken up the problem of the best way to illuminate railway gates In Germany, the level crossings in the country are often very inadequately illuminated Sometimes even an oil lamp hung from the middle of the gate is considered sufficient This can very easily be concealed by a cart standing in front of it To obviate this danger it has been proposed to place on the gates sets of two or three lamps which give an intermittent light when the gates are closed They are arranged so that it is practically impossible for all the lamps to be concealed from oncoming traffic at the same time It would be an expensive undertaking to fit all unprotected crossings in Germany with warning signalling apparatus The advisability of such devices is universally admitted, but it is not clear whether the State railways or the highway boards should bear the great expense of installing them

THE forty first congress of the Royal Sanitary Institute will be held at Margate on June 21–28, under the presidency of the Right Hon Lord Cornwallis The sections and their presidents are as follow Preventive medicine, Sir Andrew Balfour, engineering and architecture, Sir Henry Maybury, maternity and child welfare, including school hygiene, the Lady Howard de Walden, hygiene of food, Mr H Williams, hygiene in industry, Mr F W Goodenough, veterinary hygiene, Major General Sir John Moore Conferences of sanitary authorities, health visitors, and others will also be held Among the subjects to be discussed are psittacosis, maternal mortality, public health service and school medical inspection and treatment, health of industrial workers, education of the health personnel, inspection of food-stuffs, food in relation to dental hygiene, and regional control of sewage purification works Dr O Charnock Bradley, principal of the Royal (Dick) Veterinary College, Edinburgh, will deliver the Congress lecture, taking as his subject "Diseases of Domestic Animals from the Human Angle", on Tuesday, June 24 A feature of the Congress will be the visit of two hundred representatives of the American Public Health Association An exhibition of appliances for the promotion of public health and sanitation has also been arranged

THE German Association for Natural Science and Medicine has visited in recent years Innsbruck in the south, Dusseldorf in the west, and Hamburg in the north This year the Association will proclaim science and civilisation at Konigsberg in the far east of Prussia The invitation circular is not to members of the Association alone, but also to all who honour German science, and makes welcome the participation of foreign savants who feel themselves in contact with German research This ninety first assembly of the "Gesellschaft Deutscher Naturforscher und Aerzte" takes place on Sept 7–11, 1930 There will be general addresses, a short programme of sectional meetings, and numerous joint discussions Festivities are to be limited in favour of the call of learning The main topics include protoplasm, bird migration, logic and

natural science, the natural system of the elements, agriculture, and economics. The medical side will discuss blood pigments and bacteria, and will combine with biologists to discuss inheritance and with physicists to consider the eye. Joint discussions will deal with the cosmic frequency of the elements, the age of the earth, the synthesis of silicates and cosmic radiation. Botanists and agriculturalists will discuss meteorology. Various allied scientific societies are holding their meetings at the same time and place. The programme of excursions includes the neighbouring sand dunes, lagoons, bathing resorts, fresh water lakes, and historic monuments. Longer journeys include Finland for mineralogists before the meeting, and after the meeting Leningrad and Moscow. Königsberg can be reached from Berlin without any further visa, passport, or tax; eight times daily by train in 9-10 hours; by fast motor ship *via* Swinemunde-Zoppot-Pillau, 18 hours at sea; also thrice daily by air in 4-5 hours. The subscription for those attending the meetings, but not regular members, is 25 rm.; applications should be sent to Secretary G.D.N.A., Prof. Dr. Rassow, Leipzig C 1, Gustav Adolfstr. 12, and if possible by mid-May by those wishing to join excursions.

THE report on the work of the National Illumination Committee of Great Britain, presented by the chairman at the annual special meeting on Jan. 30 last, which has recently been issued in pamphlet form, illustrates the widening activities of this Committee. Following recent international congresses, a considerable number of sub-committees has been formed, and a brief summary of the proceedings of each is presented. Amongst such sub-committees those dealing with coloured glass for signal purposes, traffic control signals, daylight illumination, colorimetry, lighting education, definitions and symbols, automobile headlights, factory and school lighting, street lighting and aviation lighting may be mentioned. In five cases the British committee has assumed secretariat responsibility, which involves the collection of information from abroad. The work of the Illumination Section of the British Engineering Standards Association, which is closely allied to that of the National Illumination Committee, is also reviewed. Technical committees dealing with nomenclature and definitions, lighting fittings, street lighting, electric lamps and optical projection apparatus are mentioned. Preparatory work in connexion with the International Illumination Congress to be held in Great Britain in 1931 is actively proceeding. Judging from the developments summarised in this report, Britain should be able to present an impressive record of work done.

THE tenth Report of the Committee of the Institution of Civil Engineers which is investigating the deterioration of structures in sea water has recently been published by H.M. Stationery Office (2*s*. net). It follows now familiar lines, recording the progress of the numerous test specimens exposed in various harbours of the world. Tests of iron and steel bars which have been corroded for five years at Plymouth showed that the interior of the metal was unaffected, normal tensile tests being obtained after machining off the corroded surface. Heat treated and polished bars of chromium steels were found after five years to be deeply pitted by sea water, although the polish remained perfect between the pits. Similar bars were quite unaffected by exposure to air or fresh water for the same time. Of the numerous tests made to determine the protective effect of different paints, mention should be made of the high degree of protection given by a coat of white lead over tar, such plates being in perfect condition after 17 months at half-tide level. Of the experiments on wood a remarkable result is the very high concentration of arsenical compounds necessary to protect against *Teredo*. The addition of naphthalene to creosote appears to be of advantage. The behaviour of concrete is to be studied by means of a further series of test specimens.

THE first conversazione this year of the Royal Society will be held at the Society's rooms on Wednesday, May 14, at 8.30 P.M.

DR. J. BRONTË GATENBY, professor of zoology and comparative anatomy in Trinity College, Dublin, has been appointed Theresa Seessel Fellow of Yale University and will work there at experimental cytology from Sept. 25 next until April 9, 1931.

THE Lord President of the Council has appointed Sir Ernest Rutherford, president of the Royal Society, to be chairman of the Advisory Council of the Department of Scientific and Industrial Research in succession to Sir William McCormick as from Oct. 1 next. Prof. V. H. Blackman will serve as chairman until October.

SIR JOHN FARMER, formerly professor of botany in the Imperial College of Science and Technology, London, and Prof. Edmund Beecher Wilson, Da Costa professor of zoology in Columbia University, New York, have been elected honorary fellows of the Royal Microscopical Society.

THE twentieth meeting of the Australasian Association for the Advancement of Science will be held in Brisbane during the week commencing May 28, under the presidency of Mr. E. C. Andrews, Government Geologist, Sydney. The local honorary secretary for the meeting is Dr. D. A. Herbert, the University, Brisbane.

THE Linnean Gold Medal for 1930 of the Linnean Society of London has been awarded to Prof. J. P. Hill, professor of embryology, University College, London, and the Trail Award and Medal has been awarded to Dr. Kathleen Bever Blackburn, of the Botanical Department, Armstrong College, Newcastle-on-Tyne. The presentations will be made at the anniversary meeting to be held on May 24.

"NATIONAL Baby Week" is to be celebrated in Great Britain this year on July 1-7, and the National Baby Week Council (117 Piccadilly, W.1) suggests that at conferences special attention should be given to (*a*) the need for a national maternity service scheme, (*b*) better provision of nursery schools, and (*c*) spread of knowledge of parentcraft.

The thirty fifth general meeting of the German Bunsen Society (Deutsche Bunsen Gesellschaft) for experimental physical chemistry, the leading German society in this field, will be held at Heidelberg, for many years the scene of Bunsen's work, on May 28–June 1 The principal subject for discussion will be spectroscopy and formation of molecules The names of those desirous of participating should be sent to the "Ortsausschuss der Deutschen Bunsen Gesellschaft, Heidelberg, Ploeck 55", with particulars of any accommodation required

Owing to the prevalence of psittacosis or parrot fever in England and Wales during the last two months, the Minister of Health has issued an Order prohibiting as from May 20 the importation of parrots into the country (Statutory Rules and Orders, 1930, No 299, Covering Circular 1108 London H M Stationery Office) 'Parrot' includes macaws, cockatoos, love birds, lories, and others The prohibition does not apply, under safeguards, to birds required for research, or consigned to the Zoological Society of London

Curtis's Botanical Magazine, the beginning of periodical illustrated botanical literature, first appeared in 1787, and has an unbroken record of continuity Beginning in 1827, each volume has been dedicated to an eminent botanist or horticulturist, and the Royal Horticultural Society, which now owns the magazine, is arranging to publish a commemorative volume with a short life history of these persons, with their portraits Of the portraits required, only seven now remain to be obtained, namely Rev John Clowes (1777–1846), Capt Sir James Everard Home (1798–1853), George Curling Joad (died 1881), John Parkinson (died 1847), Sir Law(u)rence Peel (1799–1844), Mrs Sherbourne, and Mrs Wray Any information regarding these portraits should be addressed to the Secretary, Royal Horticultural Society, Vincent Square, S W 1

Farmers' and farm workers' associations and clubs, chambers of agriculture and horticulture, students' societies and other bodies interested in agriculture or market gardening, are invited to inspect the Rothamsted and Woburn Experimental Plots during the coming summer under the guidance of Mr H V Garner and Capt E H Gregory At Rothamsted the soil is heavy, and the experiments deal with the manuring of arable crops, especially sugar beet, potatoes, mangolds, fodder mixtures, barley, oats, wheat, and meadow hay At Woburn the soil is light, and the experiments there are concerned more particularly with the manuring of potatoes, sugar beet, malting barley, wheat, and the use of green manures All communications and requests to visit the Stations should be addressed to the Secretary, Rothamsted Experimental Stations, Harpenden

The Ministry of Health has issued a 'scheme' providing for the payment of contributions by county and county borough councils to voluntary associations which provide services for the welfare of blind persons, an explanatory circular (No 1086) accompanies it The scheme has been made under Section 102 (1) of the Local Government Act, 1929, and came into force on April 1 last Without such assistance the lot of the blind would be a pitiable one An article in the January–March issue of *The World's Health* (vol 11, No 1) points out that a large proportion of blindness is preventable and that an International Association for the Prevention of Blindness has been created, supported by twenty-eight countries, the League of Nations, the League of Red Cross Societies, and others

The Statistical Report of the Health of the Navy for the Year 1928 has been recently issued (London H M Stationery Office, 5*s* net) The returns for the total force, 90,820 strong, for 1928 show decreases in the incidence of disease as compared with the five years' average and with 1927 The total number of cases of disease and injury was 40,505, equal to a ratio of 445 99 per 1000, a decrease of 26 64 in comparison with the five years' average and of 33 06 in relation to 1927 The strictest attention is paid, especially in foreign waters, to sterilisation of water and milk, as well as to the control of dangerous articles of diet, with the result that only seven cases of typhoid and paratyphoid fevers occurred Venereal diseases, though showing some decrease compared with the five years' average, number 6175 cases, a slight increase relative to 1927 Malaria, with 469 cases, also shows a slight increase

A biography of Erasmus Darwin, author of "Zoonomia" (1794 96) and grandfather of Charles Darwin, has been written by Mr Hesketh Pearson and will be published shortly by Messrs J M Dent and Sons, Ltd Mr Pearson is a direct descendant of Darwin, and had access to his commonplace book and letters, as well as to family documents and other unpublished material

Applications are invited for the following appointments, on or before the dates mentioned —An assistant lecturer in engineering at the Cardiff Technical College—The Principal, Technical College, Cardiff (May 17) A lecturer in mathematics and a foundry instructor at the Constantine Technical College, Middlesbrough—The Director of Education, Education Offices, Middlesbrough (May 19) A junior engineer under the Safety in Mines Research Board, for research on colliery wire ropes—The Under Secretary for Mines, Establishment Branch, Mines Department, Dean Stanley Street, S W 1 (May 19) An assistant engineer and lecturer in the School of Civil Engineering of the Gordon Memorial College, Khartoum — The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S W 1 (May 20) An assistant lecturer in mathematics at the Belfast Municipal College of Technology —The Principal, Municipal College of Technology, Belfast (May 20) Lecturers in mathematics and metallurgy at the Sir John Cass Technical Institute—The Principal, Sir John Cass Technical Institute, Jewry Street, E C 3 (May 22) An assistant lecturer in metallurgy at the County Technical College, Wednesbury—The Director of Education, County

Education Offices, Stafford (May 24) Evening teachers for building construction, carpentry, and joinery at the Richmond Technical Institute—The Education Secretary, Hotham House, Heron Court, Richmond, Surrey (May 24) An engineering assistant in the City of Nottingham Water Department—The Town Clerk, Guildhall, Nottingham (May 26) An assistant lecturer in the department of zoology and geology of University College, Southampton—The Registrar, University College, Southampton (May 26) An assistant lecturer in the department of metallurgy of the University College of Swansea—The Registrar, University College, Swansea (May 28) An assistant lecturer in political science at the London School of Economics and Political Science—The Secretary, London School of Economics, Houghton Street, Aldwych, W C 2 (May 29) A professor of zoology in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C 2 (Aug 31) A lecturer in mathematics at the Diocesan Training College, Ripon—Miss Eva Lett, 14 Ladbroke Square, W 11 A civil engineering draughtsman under the South Staffordshire Waterworks Company — The Engineer in Chief, 26A Paradise Street, Birmingham Temporary assistant chemists in the Admiralty Chemist's Department, Portsmouth—The Admiralty Chemist H M Dockyard, Portsmouth

Our Astronomical Column

New Comet, 1930 d—A new comet of the tenth magnitude was found by Prof Schwassmann and Dr Wachmann at Bergedorf early on May 2, it is the fourth comet that they have jointly discovered, it makes the fifth observed comet to pass perihelion in 1930 The following positions for 1930 0 have been telegraphed by the I A U Bureau, Copenhagen

Date	R A	N Decl	Observers	Place
d h m	h m	° ′ ″		
May 2 0 38 2 U T	16 1 40	35 57	Schwassmann and Wachmann	Bergedorf
2 22 0 5	16 3 50 13	36 6 20	Struve	Neubabelsberg
3 21 39 3	16 6 46 00	36 17 35	Vinterhausen and Möller	Copenhagen

The roughly estimated position for the evening of May 10 is R A 16^h 28^m, N Decl 37° 42′, about 2¾° S W of η Herculis

The Total Solar Eclipse of April 28 in California—Extensive preparations were made by the Californian astronomers to utilise the brief totality of this eclipse to the utmost The eclipse afforded especial opportunity for observations of the flash spectrum, it was also hoped to obtain some photographs of the inner corona Observers in aeroplanes were to try to photograph the moon's shadow on the ground No astronomical reports are yet to hand, but from the telegrams in the daily papers it appears that the weather was clear It will be remembered that the predecessor of this eclipse in 1912 was just total in Portugal, and narrowly annular near Paris In 1858 it was almost total in England

The Lowell Planet—The Flagstaff orbit for this planet, with eccentricity 9/10 and period 3200 years, is still very uncertain Prof Banachiewicz and Dr C Smiley have calculated parabolic orbits on the hypotheses (1) that the motion is inward, which gives perihelion in 1958, (2) that it is outward, which gives perihelion in August 1902 Ephemerides on the two hypotheses are given in A U I Circ No 274 for the last three years Even in November 1927 the two orbits give positions differing by 8′ only, so that a longer arc than that of two months is required for a trustworthy result The node is now known to be within 1′ of 109° 22′, the inclination is within half a degree of 17° 10′, it is noteworthy that these two elements were predicted nearly correctly by Prof W H Pickering in his 1919 forecast, which also gave the present longitude correct within 5° He gave node 100°, inclination 15°, with estimated uncertainty 5° in each The present distance from the sun does not differ from 41 by more than a unit, but it is doubtful whether it is increasing or diminishing, increase is more probable Several orbits are given by E C Bower and F L Whipple in *Lick Bulletin*, No 421, four ellipses are given with periods 229 yr, 390 yr, 264 yr, 264 yr, also two parabolic orbits Prof W H Pickering states in a letter that he has found a period of 210 yr Unless images should be found on old plates, no decision on the eccentricity or period is possible until a longer arc is available

Harvard Announcement Card No 123 states that Mr Henroteau and Miss Burland have discovered an object on plates taken at Ottawa in 1924 that appears to be trans Neptunian, it cannot be the Lowell object, being too far north, the following positions are given, referred to the equinox of 1875 0

1924 Feb 7 666 G M T	R A 6^h 36^m 55^s	N Decl	23° 42 4
24 556	Position not given		
29 560	6 35 40		23 30 3

The magnitude is not given

From these figures Dr A C D Crommelin derives the following circular elements referred to equinox of 1924 Distance, 39 82, period, 251 3 years, node, 280° 29 4′, inclination, 49° 7′ In the Lowell planet the circular hypothesis gave a good approximation to the distance, so it may do so here also

New Constellation Boundaries—At the Leyden meeting of the International Astronomical Union in 1928, Commission III was requested to prepare maps of the constellations simplifying the constellation boundaries M E Delporte, with a committee to assist him, undertook this task, and the resulting star atlas has just been published by the Cambridge University Press The rule has been followed that the boundaries should be formed by lines parallel or perpendicular to the equator of 1875 The objection was raised at Leyden that the constellations have already lasted for thousands of years, and may last for a long time in the future, in which case the boundaries will become much inclined to the equator The ecliptic would have been a more stable direction However, on the basis that was adopted the work has been very well done, and the maps giving the new boundaries show also the stars down to magnitude 6 inclusive The boundaries have been laid down on the principle that variable stars should be kept in the same constellations as before, and that there should be as little disturbance as possible of stars that bear constellation letters or numbers The boundary between Pisces and Aquarius is so laid down that it will be about 6½ centuries before the equinox enters the latter constellation

Research Items

The Nisenan.—Mr. A. L. Kroeber publishes in vol. 24, No. 4, of the *University of California Publications in Archæology and Ethnology*, a study of a section of the Nisenan or Southern Maidu. Those with whom he deals are the valley people, who differ from those of the hills, though the two groups are sometimes classed together, on the ground of their unity of speech. In fact, Nisenan is not a specific tribal name, but is used in default of a native ethnic name. The Nisenan, now practically extinct, lived near Sacramento on the American and Feather Rivers. From the geographical and topographical information obtained, it was clear that native communications prevailingly followed the large streams, and therefore the ethnic outlook was directed towards the north and north-west within the Great Valley. The San Joaquin portion of the Valley was foreign. It seems that the groups tended to segregate themselves according to physiographic areas. Their dwellings were earth-covered, but at the mouth of Feather River they were tule-covered. They used as boats balsas made of tule and an approach to the canoe in the form of a log raft. Clothing comprised bark or tule aprons and duck feather blankets for the women, round shawls of tule for the men, and occasionally moccasins of buckskin. Their weapons were the bow with arrow points of obsidian, a spear of willow, used only in war, and a sling. The chief was selected when he was young, and succession was usually from father to son. Marriage within the village was not forbidden. Those who died of disease were cremated; but those killed in war were buried, as were also small children. A bear skin and ornaments were put on a dead person so that he should not trouble his living kin. The Kuksu cult or religious organisation comprised two societies with separate initiations. One was confined to men, the other took in a limited number of men and women. The dances were held in the summer in the dance house. The members of the *te'me'ya* ceremony or society wore a white ornament in the septum of the nose, which was bored for the purpose.

Acquired Characters.—The possibility that acquired characters may be inherited pushes itself more and more into the foreground, and Dr. M. F. Guyer's address to the Section of Zoological Sciences at the American Association for the Advancement of Science, on the last day of 1929, was a plea for further consideration of a theory which, twenty years ago, was regarded as discredited (*Science*, p. 169, Feb. 1930). He reviews some of the results of recent genetic studies by Muller, Metcalf, Goldschmidt, and others, and is led to ask whether the gene itself, or that larger vital unit of which it is a part, is really the fixed unvarying thing it is tacitly regarded to be. Genes must be nourished like other living things, since they multiply and grow and apparently display the other characteristics of living matter. They must therefore be open to the vicissitudes which beset other living substance. Once it is conceded that the constitution of the gene may wax and wane, then the way is open to the conception of how this may be induced through nutritive, toxic, or functional means. An acquired character might become an inherited character by some sort of germinal fixation that establishes it as part of the more habitual expression of the germ-plasm. The plasticity of the organism, to which these adaptations are attributed, must itself have genic significance, for the fact remains that the organism has the inherent capacity for acquiring the somatic modification.

Adelginæ (Phylloxeridæ) of North America.—In the *Stanford University Publications*, Biological Sciences, vol. 6, No. 1, Dr. P. N. Annand has a useful contribution towards a monograph of the American species of the group formerly known as the Chermesinæ and now, owing to changes of synonymy, termed the Adelginæ. In this work he describes and figures all the known American species, and gives a useful review of our knowledge of the biology of this exceedingly difficult subfamily of the aphides. Few groups of insects have so complex a life-cycle, or so great a range of polymorphism as is exhibited by the Adelginæ, while their importance, as pests of Conifers, renders it necessary that their economy should be adequately understood. Their primary host, so far as is known, is the spruce, while the intermediate hosts include such genera as *Larix*, *Pinus*, *Abies*, *Pseudotsuga*, or *Tsuga*, as the case may be. Some species, however, are confined to the primary host, and others to the intermediate host without migration between the two. For the most part, however, migration takes place and this fact has an important bearing upon control measures. What is known of the life cycle of these insects is due to the labours of a number of European investigators of several nationalities. A general summary of their work is provided and the terminology of Marchal is adopted in the systematic accounts of the American species. The latter form the greater part of the memoir and are drawn up with evident care and exactness. Dr. Annand's work brings together the essentials of what is known concerning these insects and should provide a stimulus to a better knowledge of the American species.

Buttress Roots.—Mr. T. Petch has an interesting note on this characteristic occurrence in the tropical forest in the *Annals of the Royal Botanic Gardens*, Peradeniya, vol. 11, part 3, January 1930; this is illustrated by some excellent photographs, which are, however, incompletely labelled for identification, whilst a text figure referred to in the paper frequently seems to be missing entirely. Buttress roots have usually been explained along teleological lines as supports to massive crowns, or as determined in position by prevalent winds. Mr. Petch's examination of their distribution does not confirm these theories, nor does he find them confined to the trees of the tropical rain forest. He points out the value, for observations and experiments upon this problem, of a tree like *Poinciana regia*, which shows wide differences as to the occurrence and distribution of such buttresses. He points out that in this species they may be found in young trees two to three years old, growing in quite sheltered positions; incidentally, he notes their occurrence in a seedling from a parent tree which was quite free from buttresses. He suggests as a working hypothesis that the presence of buttress roots is associated with a deficient tap root and that their formation is due to the restriction of the food and water currents to limited narrow regions of the stem continuous with the lateral roots. Mr. Petch also describes very interesting plank buttresses where the lateral stems join the main trunk, well above the ground, in some trees of *Canarium commune*; this occurrence, less commonly noted than the typical buttress roots, is illustrated by a very striking photograph.

Wankie Coalfield and its Fossil Flora.—*Bulletin* No. 15 of the Geological Survey of Southern Rhodesia is of particular interest in view of the discussion now

proceeding as to the age of the late Palæozoic glaciation of Gondwanaland Mr B Lightfoot describes the geology of the central part of the Wankie Coal field The Karroo succession ranges from the Lower Wankie sandstones to the Batoka basalts, the former resting on a floor of Archæan gneisses No intervening representative of the Dwyka conglomerate has been found in any of the exposures, but as this horizon elsewhere is older than the Wankie sandstones, the age of the latter is of critical importance Dr J Walton has already announced in NATURE (Oct 19, 1929, p 614) the significant discovery in the Upper Wankie sandstones of several species and genera of plants which are characteristic of the European type of Upper Palæozoic flora No such assemblage has hitherto been found in association with *Glossopteris* Dr Walton describes this mixed flora in a beautifully illustrated contribution to the *Bulletin*, and concludes that the evidence favours a Lower Permian or greater age for the Upper Wankie sandstones The South African glaciation is therefore early Lower Permian or late Carboniferous

French Floods of 1930 —The disastrous floods in the Midi of France early in March this year are described by M L Fournier in an illustrated article in *La Nature* for April 1 It is clear that the amount of rainfall, though heavy, was not alone responsible Thus at Clermont Ferrand the falls in January and February were 40 mm and 30 mm compared with the mean average of 35 mm and 32 mm At Nîmes the figures for the two months were 167 mm and 108 mm against a normal fall of 47 mm and 45 mm At Montpellier and Perpignan the excess was comparably as great But this excess of rainfall would not alone have caused floods of such magnitude had it not melted considerable winter snowfall and so enormously increased the deluge of water Furthermore, the rivers flowing to the west, the Aveyron and the Tarn, with their tributaries, flow in deep ravines which of course prevent the flood waters spreading and increase their disastrous effect The deforestation of the Cevennes and adjoining regions had much to do with the violence of the floods, in allowing the water to sweep over the surface instead of soaking into the soil held in place by matted roots Much of the destruction of buildings and bridges was certainly due to tree trunks swept against them, but these were isolated trees that were of no help in diverting the quick drainage of the hill sides

Electron Diffraction Rings —Some remarkably fine photographs of electron diffraction rings have been published by H Mark and R Wierl in the *Zeitschrift fur Physik* for Mar 18 They were obtained by passing electrons with velocities equivalent to between 30 and 50 kilovolts through sheets of aluminium, silver and gold about 10^{-6} cm in thickness, and are mostly analogous to the rings obtained in the powder method of X ray analysis The extreme sharpness of the rings is largely due to the fact that the time of exposure of the recording film has now been reduced to a fraction of a second, during which there is little chance for conditions to change within the apparatus The importance of this work lies partly in the information that it gives concerning the law of scattering of electrons by atoms, and partly in the fact that it is a step in the development of a new technique for the examination of thin films

Flow of Underground Water —In a paper entitled the "Exponential Law of Subsoil Flow", read by Dr N K Bose before the Punjab Engineering Congress, 1930, an interesting light is thrown on the difficult subject of the flow of underground water From observations upon a series of wells, from one of which water was pumped, Dr Bose shows that the ratio of any increments in the rise of the water level varies as the times of these rises, thus

if S_0 = the depression below rest level at time t_0
S_1 = " " " " t_1

$$\log_{10}\frac{S_0}{S_1} = -\lambda(t_1 - t_0)$$

The observations on several wells were carried out during a period of 8 days and appeared to confirm this relationship It is analogous to Slichter's relationship where, in the above, λ is a function of the yield and dimensions of the well Rewriting the above in the form

$$S_1 = S_0 e^{\lambda(t_1 - t_0)}$$

the author proceeds to correlate this exponential relationship with the similar laws of velocity flow (Stockes's equation) of viscous fluids

Anode Spots —In addition to the well known striations of the electric discharge in gases, another periodic structure occasionally appears in the form of a highly symmetrical arrangement of bright spots on the anode One investigation of the conditions under which these appear was reported by O S Duffendach and C H Thomas in the first January number of the *Physical Review*, and a second paper on the same subject has been published recently by J Oishi and K Yosiaka in the *Proceedings of the Physico Mathematical Society of Japan* (vol 12, No 1, January 1930) Cases have been recorded in which upward of seventy spots have formed on an anode a few square centimetres in area Occasionally the rings of spots rotate, presumably under the action of the magnetic field of the current passing through the discharge tube, but neighbouring rings of spots may move in opposite senses Spots have been found in hydrogen, carbon monoxide, nitrogen, and some other gases, but not in pure oxygen, argon, or neon The explanation of the origin of the spots is as yet incomplete, Prof Duffendach and Mr Thomas have adduced considerable evidence which tends to show that they are formed by gas being evolved from the material of the anode, and have made on this basis a study of some of the processes of evolution and absorption of gas in the discharge The Japanese investigators, however, from their work with hydrogen, question if this view is correct The regular array of spots is strongly reminiscent of a diffraction pattern

A New Lateral Extensometer —Few subjects, if any, have received more experimental attention from engineers than the measurement of Young's modulus, *E*, over a very wide range of conditions, and many extensometers such as those of Ewing and Marten are in common use On the other hand, apparatus for determining Poisson's ratio, η, are relatively few Among those who have devised such instruments is Prof E G Coker, who in *Engineering* for April 11 describes a new form of the lateral extensometer designed some years ago by Dr Scoble and himself An essential feature of such delicate instruments for measuring small displacements is that the forces produced in it should be minute, and this is obtained by the chief control being exerted by a light spring In general the instrument consists of a horseshoe frame carrying between its jaws two pointed spindles, one of which is provided with a micrometer screw, while the other presses against the short arm of a bell crank lever, the longer arm of which is connected to a small mirror which can rotate through a small angle The movement of the mirror will be proportional to the contraction of the specimen The horseshoe frame is mounted on a compound slide rest which in turn is

pivoted to a block which can be moved up and down a vertical pillar fixed in the base of the mounting One illustration shows the extensometer in use on a rod under tension, the reflected spot of light from the mirror being recorded autographically on a vertical revolving cylinder

Oxidation of Benzene —An investigation of the kinetics of the oxidation of gaseous benzene is reported by C N Hinshelwood and R Fort in the April number of the *Proceedings of the Royal Society* It has been found that the reaction is predominately homogeneous A first stage which occurs without change in pressure is followed by further oxidation of the initial products by a mechanism not unlike that of the oxidation of ethylene and acetylene, probably first to glyoxal, formaldehyde, and formic acid, and finally to steam, carbon monoxide, and a little carbon dioxide It appears that the reaction is of the chain type, and from the greater sensitivity of the rate of reaction to benzene concentration than to oxygen concentration, that the chains are propagated more readily when the initial oxygenated product encounters another molecule of hydrocarbon than when it is oxidised further by oxygen

Vapour Pressure of Solutions —A modified form of wet-bulb hygrometer suitable for the measurement of vapour pressures has been described by Prof A V Hill in the April number of the *Proceedings of the Royal Society* A symmetrically constructed thermo pile is set up in a test tube, in which the vapour pressure is maintained practically constant by the presence of a suitable solution supported on filter paper Two other strips of filter paper are moistened with the two solutions to be compared, and are laid one on each face of the thermopile, when a difference in temperature is set up on account of the different rates of condensation which is proportional to the difference between the vapour pressures of the solutions on the two faces The constant of the instru ment is found by calibration with known solutions It takes rather more than half an hour to obtain a reading, and the error of a single observation is of the order of 1½ per cent of the difference read This method for measuring vapour pressures has the great advantage that it requires very small quantities of the solutions, whilst it has a wide range, it being possible to measure, on one hand the difference in vapour pressure between 0 1 *M* sodium chloride and 0 2 *M* cane sugar, or, on the other, the difference between 5 *M* sodium chloride and water, the latter difference being of the order of 500 times the former

Dielectric Constants of Water and Hydrogen Peroxide —Measurements of the dielectric constant of water at various temperatures, made by Cuthbertson and Maas, are given in the February number of the *Journal of the American Chemical Society* The tem perature range used was 0° 75° The results of previous observers are divergent, and little attention has been paid to the measurement of the temperature coefficient over a wide range The values at 0°, 15°, 25°, 50°, and 75° C were found to be 84 4, 78 5, 75 4, 69, and 62 9, respectively From 25° to 75° the rela tion to temperature is approximately linear, at lower temperatures the numerical value of the coefficient is greater The authors point out that the value at room temperature, 18°, namely 77 0, is appreciably lower than the mean of the values found by other observers, namely, 81 05, whilst their values for non conducting liquids found with the same apparatus agree well with the accepted values They also note that the Debye equation for polarisability has no significance for a liquid such as water, in which the tendency to association probably varies with the temperature A second paper by the same authors deals with hydrogen peroxide, the dielectric constants of which and its aqueous solutions were measured A maximum occurs at 35 per cent of hydrogen peroxide The value for pure hydrogen peroxide is 89 2 at 0° The specific conductivity was less than 2×10^{-6}, indicating only very slight dissociation

Active Nitrogen — The March number of the *Journal of the Chemical Society* contains a further paper by E J B Willey on active nitrogen, in which the decay of the afterglow has been especially studied Previous work indicated that the ternary reaction $2N + N_2 = 2N_2$ + glow would provide an explanation of the negative temperature coefficient of the decay, but further work showed that the process was to be represented as $2N + 2N_2 = 3N_2$ and that the luminosity and chemical activity are closely related, and not independent as formerly suggested Other workers have found that the spectrum of the afterglow is independent of the nature of the impurities which must be present to cause nitrogen to develop its glow when sparked, and the view has gained ground that these 'photogens', as they are called, poison the walls of the vessel and prevent recombination of atoms thereon If this theory is correct, a quantita tive relation will exist between the decay mechanism and the purity of the nitrogen, and this was investi gated experimentally, the glow being measured by means of a photo cell The afterglow was found to be probably partly homogeneous and partly hetero geneous, according to experimental conditions Unless the walls of the vessel are poisoned by foreign gases, the recombination process is non luminous and occurs as a surface reaction As the concentration of impurity rises, the wall reaction diminishes and the homogeneous decay increases The afterglow probably originates in a reaction $N + N^1 = N_2^1$, $N_2^1 + N_2 = 2N_2$(+ afterglow), N^1 being a metastable 2 3 volt atom which is the chemically active species the energy of which has been measured earlier No changes are to be seen in the order of decay as it proceeds, neither do the spectral characteristics of the glow between 5900 A and 4000 A appear to alter

New Developments in Technical Electrolytic Processes —A lecture given by Prof Billiter to the Society of Austrian Chemists forms the subject of a lengthy article in the *Chemiker Zeitung* for Mar 12 Tribute is paid to the excellent work which has been done in this field by Americans Whereas it was generally supposed twenty years ago that electrolytic methods would gradually be replaced by thermo electric pro cesses, it is now realised that electrolysis is destined to play a leading part in technical operations in the future Amongst the processes which are carried out in aqueous solutions the following are described the refinement of copper, the extraction of zinc, the electrolysis of water, and the preparation of hydrogen peroxide The increased demand for pure water which is needed for electrolytic operations and for filling accumulator cells, has led to the development of methods of purifying water by electro osmosis, which yields a purer product than distillation Im portant progress has also been made in the use of molten electrolytes, particularly fluorides, by means of which the technical production of beryllium has become possible and improvements have also been made in the extraction of sodium and aluminium Sodium can now be obtained from the molten chloride, and aluminium is refined by the electrolysis of molten fluoride to a higher degree of purity than was possible in the older process The use of molten fluorides in electrolysis is rapidly becoming more common

The Future of British Agriculture

MANY people to day are searching for remedies for the depression that hangs so heavily over agriculture, particularly in Great Britain In a recent paper before the Surveyors' Institution, Mr T Wibberley makes his contribution to the problem, and envisages a future for British agriculture when it will rest, even more than to day, on livestock This will be achieved, in his opinion, not by the further extension of grassland, but rather by using arable land, to a much greater extent than at present, for the production of food for livestock, by the growth of forage crops, either for grazing, or for cutting for hay or silage, or for harvesting as mixed grain, and by keeping the land more continuously cropped

Livestock certainly holds out more promise than most other branches of farming Sir William Haldane has forecast a reasonably bright future for beef production at home, provided it be of good quality and that there are no great developments elsewhere, as yet unforeseen The stock population of Great Britain has lately decreased all round, and, if our beef has to face competition from chilled imports of high quality, our mutton is free from similar competition because of transport costs, our pork is at present protected by the import embargo, and there is abundant room for greater bacon production if we could but compete successfully with the Danish article In addition, we still have a sheltered market for milk, a market capable of considerable expansion by educating the public to the value of milk for children the poultry industry also is developing

As against this, grain can be produced so much more cheaply in other parts of the world that it can be transported for thousands of miles and still compete successfully with the home grown product It would appear unsound to base the future of our agriculture on the production of uneconomic crops At the same time, it is difficult to picture a farming system without grain, and even where it is uneconomical to sell, the farmer can feed more of his own grain to stock In successful farming systems in Great Britain or in Denmark at the present time, nearly half the arable area is still devoted to grain, indeed, Denmark recovered from the depression at the end of last century without appreciably altering the proportion of arable area devoted to grain Since the period 1889–93 this proportion has been consistently 2 or 3 per cent below that of England, but about 14 per cent greater than that of Scotland, where more use is made of temporary leys Grain crops are needed for the production of straw, required by the animals on the farm Arable land cannot yet be farmed successfully without farmyard manure, whether it be made naturally or by chemical means

The proportions of arable land devoted to different crops in the various periods from 1889 to 1927 is as follows

	1889–93			1899–1903			1909–13			1923–27		
	England	Scotland.	Denmark	England	Scotland	Denmark	England	Scotland	Denmark	England.	Scotland	Denmark
Corn crops	52	36	49	50	36	49	52	36	46	51	35	49
Roots	17	17	5	17	17	9	18	18	14	17	17	18
Green crops	27	46	39	30	47	36	27	46	35	28	48	31
Fallow	4		7	3		6	3		5	4		2

'Roots' includes potatoes
Green crops includes temporary grass, lucerne, mustard, etc.

Denmark emerged from her agricultural crisis by increasing the root break and the livestock population, although, even now, the proportion of arable area under roots is only slightly greater than in Great Britain, and much below what it is in particular districts, such as East Lothian and the Holland division of Lincolnshire Mr Wibberley suggests a similar change now for British agriculture, except that the increased production of stock food should be in the form of various forage crops rather than roots

There seems little doubt that forage crops are cheaper to produce than roots, and this economic problem reacts on the agricultural situation in a way that is frequently overlooked The labour situation, at least in the southern parts of Great Britain, is neither sound nor stable, and no farming system can be sound if it rests on an unsound foundation The farmer, under present conditions, cannot face a higher total wage bill, but it is equally impossible to retain the best men amongst the agricultural labourers at present wages, despite all efforts at rural education, particularly if and when an industrial revival occurs The future will probably see fewer workers, and, unless agriculture is content to struggle along with inferior labour, these will be more highly paid and will produce more, many aspiring, possibly, to eventual independence Labour considerations alone indicate developments of agriculture in three directions

(1) A more extensive mechanised farming, demanding, of course, large fields and open country
(2) More stock keeping, affording scope for good well paid men
(3) Smaller holdings worked by families setting a high value on independence, and recruited from the rising generation of keen young men, such as those sons of rural workers turned out in increasing numbers by farm institutes

Mr Wibberley is not hopeful of intensive grassland management However, if only the existing grassland in Great Britain were better managed, our stock carrying capacity would be greatly increased, but this would accentuate the problem of providing sufficient food to last the winter

The extent to which arable land should be further utilised for animal food production is difficult to decide Each district or even farm must be considered separately The weather is liable to upset a complex forage cropping system, soils in drier districts may dry out, weeds may get out of control, specially if the next crop is sown on the unploughed stubble of the old, particular farms—or farmers—may not be suited to tractor work, and certain soils would prove unsuitable for continuous cropping The crops grown would also differ in those parts where high yields are obtainable, and labour is efficient, roots can hold their own At very least, better advantage could be taken of the full growing season, and an end should be made of such practices as leaving a winter oat stubble untouched until the winter, and bare of crop from August to March or April

The future of British agriculture seems to demand a closer relationship between the grassland, well managed, and the arable, a better demand for the produce, particularly that raised under sheltered conditions, a better marketing organisation, more education, and the reduction of losses which may at present be preventible or non preventible One feels on safe ground in believing that the future of agriculture in any district will continue to be largely influenced by local conditions, economic, geographic, and climatic, and in accepting the Prime Minister's phrase, "the inevitability of gradualness" H G MILLER

The Physical Reality of 'Side-bands'

By F M COLEBROOK, Wireless Division, National Physical Laboratory

THE variation of the amplitude of a continuous electric wave in a periodic manner is commonly understood as being equivalent to adding waves of certain defined frequencies to the original wave train The mathematical formulation underlying this interpretation has not been questioned, but Sir Ambrose Fleming, an eminent authority on wireless communication, has recently voiced, in the columns of NATURE, a doubt that many others may have shared as to the physical reality of the added radio frequencies attributed to the process of modulation

It is necessary to consider what is meant by the words 'physical reality' in this connexion It will probably be generally agreed that no more than the purely pragmatic criterion is involved If an amplitude modulated continuous wave is found to behave in every respect as if it consisted of waves of the original frequency associated with waves of the hypothecated side frequencies, then the latter can be said to exist physically in the only sense in which the phrase has any useful meaning

From the purely practical point of view of wireless communication, the criterion can be still further limited to those characteristics which are actually involved in the processes of transmission and reception

Prof Fortescue [1] and Mr Ratcliffe [2] have pointed out in the course of correspondence on this subject that there is experimental evidence for the physical reality of side bands in the above sense The following experiments are thought to give clear and decisive evidence to the same effect

A valve maintained oscillator was adjusted to a frequency of 40,100 cycles per second In the field of this oscillator a receiving circuit was set up, consisting of an inductance and a tuning condenser A valve voltmeter was connected across the terminals of the latter, and the ordinary tuning curve of the receiving circuit was recorded It was found to be a single peaked resonance curve of the ordinary type The oscillator was then modulated at 4010 cycles per second by means of the e m f induced in a suitably tuned circuit coupled to an audio frequency oscillator set at the above frequency The tuning curve of the receiving circuit was again recorded It is shown in Fig 1 The tuning capacities of the side peaks correspond very approximately to the frequencies 40,100 +4010 and 40,100 -4010 cycles per second This demonstrates that the modulated continuous wave behaves as if it had wave components which produce resonance in a circuit tuned to the above sum and difference frequencies

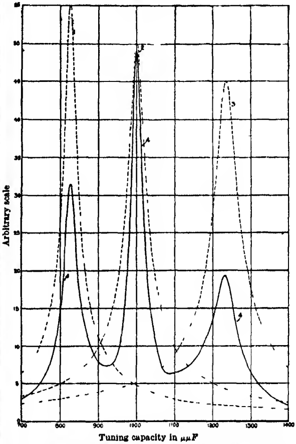

FIG 2—Curves 1, 2 3 calculated resonance curves corresponding to carrier and side frequencies assuming equal e m f s for each Curve 4 calculated variation of the modulation frequency output with tuning capacity Carrier frequency, 80,000 cycles/sec, modulation frequency, 8000 cycles/sec

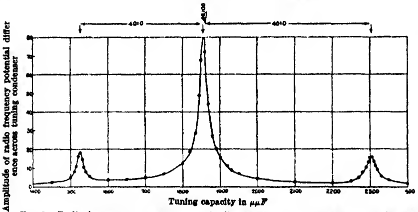

FIG 1—Radio frequency resonance curve Radio frequency, 40,100 cycles/sec, modulation frequency, 4010 cycles/sec

The next step was to investigate analytically and experimentally the result of rectifying the potential difference across the tuning condenser produced by the modulated field It is well known that the rectified current will contain a component of modulation frequency The case was analysed in general terms for square law rectification and a formula was derived expressing the variation of the intensity of the modulation frequency component as a function of the tuning capacity As a numerical example the following values were assumed

$\lambda = 3768$ metres
($\omega = 2\pi \times$ frequency $= 5{\cdot}1 \times 10^{5}$),
Modulation frequency = 7960
(i e $2\pi \times$ mod freq $= 5 \times 10^{4}$),
Receiving circuit inductance = 4 millihenries,
Receiving circuit resistance = 40 ohms

This case is illustrated in Fig 2 It will be ob-

served that there are three distinct tuning maxima corresponding very approximately (though not quite exactly) to the tuning capacities for resonance of the sum and difference frequencies Further, of the two side maxima, that corresponding to the smaller tuning capacity is taller and narrower than the other An important point is that the shape of this curve is independent of the modulation depth (that is, the relative magnitude of the amplitude change due to the modulation) The ordinates, however, are pro portional to the modulation depth

For the experimental investigation a rectifying valve was connected across the tuning condenser, and the in tensity of the modulation fre quency component of the anode circuit current was measured by means of the same valve voltmeter as was used in the radio frequency experiment Care was taken that the received voltage ap plied to the rectifier was small enough to result in square law rectification, and also that the recorded output voltage con tained no appreciable radio frequency components (these being filtered out by the action of an audio frequency trans former) The result is shown in Fig 3 The circuit constants and frequencies were different from those considered in the analytical case, and the re spective curves are not there fore in quantitative agree ment The principal features of the analytical de ductions are, however, fully confirmed, there being three distinct tuning maxima with similar relative heights and breadths (It will be noted that the radio frequency differs slightly—½ per cent, in fact—from that in Fig 1, but this is immaterial In each case the audio frequency was set to exactly one tenth of the radio frequency, to avoid interference between the latter and the tenth harmonic of the former)

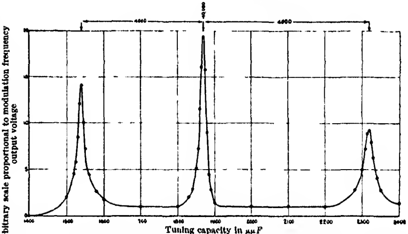

FIG 3 —Square law rectification of modulated continuous wave Radio frequency 40,000 cycles/sec , modulation frequency, 4000 cycles/sec

The above analysis was based on the usual repre sentation of the modulated wave as the sum of a carrier frequency and the two sum and difference frequency wave trains The experimental confirma tion, therefore, shows that these side frequencies exist physically in an actual modulated wave train in the sense in which that phrase has been defined above

It should be pointed out that if in another actual case the three peaks are not observed, it will not be a logical deduction that the side frequencies do not exist The matter is quite comparable with spectrum analysis in optics There is a limit to the resolving power obtainable with a spectroscope or grating Similarly there is a limit to the resolving power ob tainable in a tuned receiving circuit For example, with carrier and modulation frequencies of a million and a hundred cycles per second respectively, there would almost certainly be one peak only in the tuning curve, unless by some means, such as the use of retro action in the valve rectifier, the receiving circuit resistance were reduced to very much less than its normal value Thus the separate peaks may not be observable under medium wave broadcasting condi tions It was found, however, that three peaks were observable in another set of measurements made at frequencies comparable with those involved in long wave broadcasting

Full details of the theoretical and experimental work described above are given in a paper entitled "The Rectification of a Modulated Continuous Wave" which will shortly be published in *Experi mental Wireless*

[2] NATURE, Feb 22 1930

Kevin-Sunburst Oilfield, Montana

MUCH is heard concerning the oil possibilities of the Rocky Mountain States of North America, but in spite of all the survey work accomplished in likely regions, there has really only been one con spicuous development, Salt Creek, Wyoming, a field which is still producing well over 20,000 barrels of oil per day It is therefore encouraging to note the progress of the comparatively new Kevin Sunburst field in Montana, which, with a daily production of more than 6000 barrels and with reasonable prob abilities of extension, ranks second in importance throughout the mountain States

Oil was originally discovered at Kevin in March 1922 in a structure known as the Sweetgrass arch, an uplift comparable in many respects with the better known Cincinnati fold of Ohio The Kevin Sunburst structure is essentially a 'bulge' on the crest of the arch, located just south of the Canadian boundary In the five year period to 1927, some 1500 wells were drilled into this structure, of which more than 880 were productive, a proportion which, for the Rocky Mountain fields, is quite high The area has more than usual stratigraphical interest, since it includes a prominent representative of the Jurassic system beneath the thick spread of Cretaceous rocks so characteristic of this part of the world One does not expect extensive developments of Jurassic rocks in the Rocky Mountain States, having regard to geo logical conditions in general at this epoch, still more surprising is the fact that the best production of petroleum in this field comes from the Ellis formation of that age, from sands situated not far above the

base, an unconformable contact with the Carboniferous There is also minor production from the Cretaceous beds

The point at once arises that the Carboniferous rocks (Madison limestone) may be the ultimate source of the oil and that the Jurassic can only claim migrated supplies The unconformity is a big one, so that this may indeed be the case, though Mr A J Collier, the author of the recent bulletin on the subject (U S Geological Survey, No 812 B) giving the latest account of this field, inclines to the view that the indigenous source is the Ellis formation, and backs his opinion with data of more than local interest

University and Educational Intelligence

CAMBRIDGE —The Sheepshanks Exhibition for proficiency in astronomy has been awarded to R D H Jones, scholar of Gonville and Caius College

The Appointments Committee of the Faculty of Archæology and Anthropology has reappointed R U Sayce to be University lecturer in material culture and physical anthropology

Sir William Pope announces that Dr Ernest Fourneau, of the Pasteur Institute, Paris, will give a lecture on the Liversidge Foundation on Friday, May 9, at 5 P M , on " Chemo Therapy "

APPLICATIONS for grants from the Chemical Society Research Fund must reach the Assistant Secretary of the Society, Burlington House, W 1, not later than June 2 The requisite form is obtainable upon request

RAMSAY memorial fellowships for chemical research, one limited to candidates educated in Glasgow, will shortly be awarded The fellowships will each be of the yearly value of £250 plus, possibly, a grant for expenses They will be tenable for two years, with a possible extension of a year Applications must be sent to reach the secretary of the Ramsay Memorial Fellowship Trust, University College, Gower Street, W C 1, by June 5 at latest

STATE grants to Universities in Great Britain are to be increased by £250,000 a year For five years they have stood at £1,550,000, to which figure Sir Austen Chamberlain raised them in 1925 When the Universities presented to the Chancellor of the Exchequer last November, through a deputation introduced by Lord Cecil, the case for a further increase, they asked also for capital grants for buildings Mr Snowden recognised " the great and increasing extent to which they are serving the social and industrial progress of the people " and that " it is quite reasonable that the State should contribute in substantial measure to the cost of maintaining our universities and colleges as active centres of education and research, and few, if any, items of public expenditure can be of clearer national value ", but he holds that there is comparatively little weight in the arguments for capital grants The most cogent argument for increased assistance is based on the increased expensiveness, due to the progress of science, of the plant and staff requisite for maintaining the high standard of efficiency in instruction and research which is indispensable for national well being in the face of the economic competition of other nations in the world of commerce For the provision of new plant Mr Snowden thinks that " the fine record of benefactions received by the universities during the last four or five years encourages the hope that during the coming quinquennium private generosity may again prove not unequal to the task "

Historic Natural Events

May 11, 1894 Remarkable Hail —During a severe hailstorm at Vicksburg (U S A) a remarkably large hailstone was found to have a solid nucleus, consisting of a piece of alabaster, from ½ to ¾ inch in length During the same storm, at Bovina, 8 miles east of Vicksburg, a gopher turtle, 6 in by 8 in , and entirely encased in ice, fell with the hail These hailstorms occurred on the south side of a region of cold northerly winds , they were apparently accompanied by local whirls which carried heavy objects from the earth's surface up to the clouds, where they were encased by successive layers of snow and ice

May 12, 1811 Tornado in Derbyshire —About 5 P M at Bonsall, in the Peak district, a singular motion was observed in a cloud of serpentine form, which moved in a circular direction, from south by west to north, extending itself to the ground It began near Hopton, and continued along a course about five or six miles in length and about four or five hundred yards in breadth, tearing up plantations, levelling barns and miners' cots It uprooted large ash trees, carrying them 20 30 yards, and twisted the tops from the trunks of other trees, dropping them 50 100 yards away Cows were lifted from one field to another, and injured by the fall, miners' bubble tubs, wash vats, and other materials were carried to a considerable distance and forced into the ground The tornado was accompanied by a tremendous hailstorm , stones and lumps of ice fell which measured from nine inches to a foot in circumference, breaking windows and injuring cattle

May 13, 1922 Hailstorm at Montpellier, France -- On this date a hailstorm occurred at Montpellier, France So great was the fall that traffic was blocked in the streets, and the inhabitants were obliged to clear the pavements with shovels The hailstones averaged half an inch in diameter, and on open ground they lay to a depth of four inches, but in streets where they were washed into heaps by the accompanying rain, and caked together, they formed a layer from 1½ to 2 feet deep

May 13–17, 1921 Magnetic Storm and Sunspot — A magnetic storm of great intensity and long duration commenced on May 13 6 and lasted until May 17 At Greenwich the traces of declination, horizontal force, and vertical force passed continually beyond the recording sheets , the measured ranges of the three elements were respectively $>100'$, $>740\gamma$, and $>460\gamma$ At Kew the corresponding ranges were $132'$, $>650\gamma$, and 1500γ The storm reached its greatest intensity between 0^h and 8^h G M T on May 15 Oscillations of the needles were frequently so rapid that the movements were barely recorded on the photographic sheets The disturbance was accompanied by brilliant displays of the aurora, and there were serious dislocations of the telephone and telegraph services over a great part of the world At the time of the commencement of the storm, a large naked eye sunspot was one day's travel east of the sun's central meridian The spot, which was situated on the sun's equator, was of unusual development

May 14, 1886 Floods —Following three days of excessive rainfall in Wales and the west Midlands on May 11–13, disastrous floods occurred on May 14 and 15 At Worcester the Severn rose to 17 ft 10 in above the ordinary summer level , this was described as the highest flood for 115 years The Trent at Nottingham was nearly 19 feet above the summer level, but did not equal the flood of 1852

May 15, 1586 Waterspout —At Kestrzan in Bohemia a powerful whirlwind carried the water of two

ponds into the air with all the carp and pike that they contained On the following day there was a water spout on Lake Constance near Meilen

May 15, 1608 Cold Spring —Not only the winter of 1607–8 (see Jan 10) but also the following spring, were abnormally cold The rivers remained frozen well into the spring, and it is recorded that so late as May 15 boys were sliding on the frozen ditches at Dantzig The season was also severe in North America, and resulted in the destruction of the European colony of Sagadahoc

May 15, 1893 Drought —The famous 'spring drought' of 1893 was, while it lasted, one of the most severe on record in England and the neighbouring parts of Europe For a period of 114 days commencing on Feb 28, the total rainfall in London was only 1 09 in, and during the four months March to June less than a third of the normal rainfall was experienced in southern England At Hurst Castle (Hampshire) a period of 59 days from Mar 18 to May 15 was completely rainless, and a large part of southern England had no rain in April

May 16, 1646 Rain of Brimstone Worm relates that "the whole city of Hasnia [? Asmara Is off Italy] and all its streets were inundated with a mighty rain so that men were prevented from walking and the air was infested with a sulphureous odour, when the waters had subsided somewhat it was possible in some places to collect a sulphureous powder, some of which would pass for real sulphur as regards taste, colour, smell, etc"

Societies and Academies

LONDON

Geological Society, April 9 —**Léon W Collet** The structure of the Canadian Rockies The results of a two months' expedition (financed by the Shaller Fund) along the Athabasca Valley (Jasper National Park) and round Mount Robson (B C) A complete section across the Rockies was made, from the eastern border to Yellow Head Pass This mountain chain is made up of seven 'blocks' thrust one over the other from west to east, and separated by 'clean cut thrusts' of the type of the North West Highlands of Scotland The Canadian Rockies and the Alps show two different types of folding The structure in blocks of the Canadian Rockies corresponds to Argand's 'ground folds' (*plis de fond*), while the Alps are made up of 'recumbent folds' developed in a geosyncline In the Canadian Rockies the energy necessary for the folding was much greater than in the Alps for in the former the strata have been cut into blocks as far down as the Pre Cambrian The Ordovician and the Silurian are missing in the eastern part of the Rockies The Ordovician alone appears in the western part This stratigraphical gap is a repercussion, across the Canadian Shield, of the Caledonian folding of the Canadian Appalachians

Royal Meteorological Society, April 16 —**S K Banerji** The electric field of overhead thunderclouds Changes in the electric field produced by eighteen thunderclouds during their passage over the Colaba Observatory in 1929 suggest that the majority were of the 'unitary type' and had their front part negatively charged, the central part positively charged, and the rear negatively charged A few were of the 'double type' and produced changes in the field as if two thunderclouds of unitary type had passed over in succession In those thunderclouds which caused heavy rainfall, fluctuations in the central positive field occurred by loss of charge by rainfall or by increased concentration of positive charge by increased vertical current, in agreement with the breaking drop theory The monsoon clouds produced an electric field which was pre eminently negative during periods of rainfall —**F J W Whipple** The great Siberian meteor and the waves, seismic and aerial, which it produced On June 30, 1908 a great meteor fell in Siberia, probably the greatest meteor which has occurred in historic times The blast of air produced by the meteor devastated the forests over an enormous area Leonard Kulik explored the region in 1927 and found the numerous holes in which, it is presumed, the fragments of the original meteor are buried The impact of the meteorites caused seismic waves which were recorded at four observatories, the most distant of which was Jena Remarkable waves recorded by sensitive barographs in England were produced by the meteor The waves took five hours to travel from Siberia to England, the velocity being a little greater than that of the waves due to the famous eruption of Krakatoa

PARIS

Academy of Sciences, Mar 24 **Bigourdan** The instruments and observations of P J de Beauchamp Historical account of the astronomical instruments used at the end of the eighteenth century by Beauchamp at Bagdad and elsewhere —**A Cotton** and **M Scherer** The magnetic double refraction of specimens of petroleum from various sources Six specimens, with boiling points up to 250° C and roughly refined, were examined, the large Bellevue magnet being utilised for the observations The ratio $\frac{C_m}{d} \times 10^{14}$, where C_m was the double refraction for unit field and unit thickness, varied between 5 53 for Pechelbronn petroleum to 27 0 for the Moronic oil —**Henri Villat** and **Maurice Roy** The problem of Saint Venant in the case of pure torsion —**Alfred Rosenblatt** Certain relations between the integrals of the first species of Picard belonging to an algebraic surface **M Cioranescu** Certain inverse problems relating to potential —**Maurice Coissard** A class of partial differential equations of the first order, with two independent variables —**Antonio Signorini** A mixed problem —**T Bonnesen** Inequalities between arithmetical means —**J Dieudonné** Some applications of the lemma of Schwarz —**Henri Cartan** The analytical transformations of encircled domains —**L Ahlfors** Some properties of meromorph functions —**Elie Cartan** Linear representations of simple and semi simple groups —**R Swyngedauw** The measurement of the power dissipated in organs of transmission **N S Argeanicoff** The theory of Witoszinsky —**Alexandre Rajchman** An algebraic equation which occurs in the kinetic theory of gases —**Th De Donder** The signification and invariance of the quantic constant h deduced from gravifics —**Pierre Bricout** An absolute micromanometer with electrostatic compensation —**A Poirot** The anodic rays of sodium, potassium, calcium, and barium —**Constantin Salceanu** The magnetic double refraction of organic substances in the fused state The measurements were made with the large electro magnet of the Academy of Sciences in a field of about 43,000 gauss Data are given for β-methylnaphthalene, at temperatures between 89° C and 36 5° C, and for three different wave lengths —**R Coustal** and **F Prevet** The optimum concentration for the phosphorogen and flux in zinc sulphide, copper, and the variation of this optimum with the temperature of the preparation Copper behaves differently from other phosphorogens, especially as regards the extremely small quantities required when the temperature of preparation is high —**Guy Emschwiller** The photolysis of organic

iodides the utilisation of the light The photolysis of organic iodides is a complex phenomenon The coefficient of utilisation of the ultra violet light depends on the temperature and on the nature of the organic compound The quality of the radiation also has an effect In the calculations it is necessary to take into account the fact that the iodine set free acts as an internal screen Details of experiments on ethyl iodide are given —**Maurice François** The action of concentrated ammonia on the compound $HgCl_2 2NH_3$ The formation of monomercuriammonium chloride, $HgNH_2Cl$, and of hydrated dimercurammonium chloride, Hg_2NCl,H_2O —**J J Rutgers** The micro estimation of mercury in organic compounds The organic compound is burnt in a current of oxygen mixed with the vapour of aqua regia, the mercuric chloride formed being afterwards electrolysed Examples are given showing the accuracy of the method —**Edmond Rabaté** and **Jean Fleckinger** A colour reaction for the proteids of the wheat seed The hydrobromic acid reagent suggested by Denigès as a specific test for ionised copper is also a good reagent for the proteids of the embryo and the diastase layer of wheat seeds —**Albert Kirrmann** The condensation of pyruvic acid with the fatty aldehydes **Desmaroux** and **Mathieu** The solutions of diphenyl urea in nitrocellulose Study of the alterations produced in the X ray photographs of films of nitrocellulose by the additions of varying proportions of diphenylurea to the nitrocellulose solutions before forming the film —**M Bourguel** and **R Truchet** The action of the chlorides of the aromatic sulphonic acids on the sodium derivatives of acetylene hydrocarbons In an attempt to prepare acetylene sulphones the reaction was abnormal, there was no sodium chloride produced, the reaction found being

$$R\ C\equiv C\ Na + ClSO_2R' \rightarrow R\ C\equiv C\ Cl + R'SO_2Na,$$

a simple exchange of chlorine for sodium, the reaction products being a sulphinate and a chloro derivative of the acetylene hydrocarbon **L Berthois** Study of the heavy minerals of the granite massif of Fougères (Ille et Vilaine) Details of the isolation of zircon, tourmaline, monazite, sphene In the contact zone were found andalusite, sillimanite, and zoisite **Ch Gérard** Some particular points of the stratigraphy of the ferruginous Aalenian of Meurthe et Moselle —**André Rivière** A section observed in the middle valley of the Djerjeroud (Persia) —**H Arsandaux** The present eruption of Mt Pelée The products of consolidation do not differ from those of the previous eruption —**Mlle D Le Maitre** The presence of algæ and of foraminifera of the genus *Endothyra* in limestones of Devonian age —**A Demolon** and **G Barbier** The valuation of the phosphoric acid deficiency of soils The basis of the method is the amount of phosphoric acid extracted by the soil from a phosphate solution containing 1 per cent of acetic acid and varying proportions of phosphate It is considered that such measurements form a better criterion of the deficiency of the soil in phosphates than the determination of the amounts of phosphate extracted from the soil by the usual methods —**Emile F Terroine** and **Mlle Thérèse Reichert** Common salt in cattle feeding its action on nitrogenous metabolism —**A Vandel** The production of *intercastes* in the ant, *Pheidole pallidula*, under the action of parasites of the genus *Mermis*

GENEVA

Society of Physics and Natural History, Feb 20 —**P Chodat** A new method for the determination of the iso electric point by ferments The author communicates the results of his experiments relating to the variations of the curve expressing the activity of the ferment catalase as a function of the real acidity of the medium according to the nature of the system employed, saline or protein, normal or deviating curves are obtained Deviations are interpreted as being due to the isoelectric state of the particles of proteid utilised as a buffer —**R Wavre** The method of the cavity and the internal movements of the planets The author shows that the method of the cavity, for the discussion of the equilibrium figures relating to the fluid stars, is still applicable if the latter are endowed with permanent rotation of genus one The study of the internal movements of genus one, although longer, does not introduce essentially new theoretical difficulties compared with the study of equilibrium figures

ROME

Royal National Academy of the Lincei, Jan 5 —**T Levi-Civitá** Characteristics and bicharacteristics of Einstein's gravitational equations The general theory of characteristics developed by Volterra and Hadamard is applied to the particular case of the gravitational equations of relativity —**V Nobile** The intermediary trihedra of reference for stellar dynamics criteria of selection —**L Rolla** and **L Mazza** Systems of telegraphy and telephony by means of pencils of infra red radiations Experiments are described in which the source of the radiation is an arc between hollow carbons packed with mixtures of halides (mainly fluorides) and oxides of alkali and alkaline earth metals The modulation circuits were analogous to those used by other investigators, but were fitted with devices to render the arc more stable, while the modulation current was obtained by amplifying the microphone current by a thermionic valve The transmitter consisted of a small parabolic mirror (diameter 18 cm), of ray filters, and of a special electromagnetic vibrator connected with a Morse telegraphic transmission instrument With arcs carrying 100 watts, satisfactory telephonic communication was possible over distances exceeding 6 km —**G Tizzoni** and **G De Angelis** Certain causes which may weaken or destroy the immunising power of our phenolated anti cancer vaccine Infection of adeno carcinoma pus (Ehrlich), even with common bacteria, modifies appreciably and in some cases completely annuls the activity of the phenolated vaccine Such infection has no effect on the growth or power of the virulent cancerous pus which has thus greater resistance than the vaccine It is hence absolutely necessary that the vaccine should be bacteriologically pure —**E Bompiani** Projective interpretation of certain ordinary differential equations of the second order New results are given in connexion with the projective interpretation, already published, of certain types of differential equations $v'' = F(u, v, v')$ on a surface σ of S_3 —**L Laboccetta** Segmental interpolation and classification of polygonal functions —**C Popovici** Integro functional equations —**L Godeaux** A property of the envelope of certain families of quadrics —**B Finzi** Dynamic actions relative to plane irrotational motions of viscous liquids Formulæ are determined which permit of the characterisation of the dynamic actions exerted on a line of flux by a viscous liquid in irrotational motion The expressions obtained represent the sum of two terms, the first being independent of the viscosity of the liquid and expressible by the known formulæ of Blasius, while the second gives the effect due to the viscosity The expressions defining the viscosity are particularly simple and are analytical in character, moreover, they are valid not only for lines of flux but, unlike the expressions of the formulæ of Blasius, also for any line whatever —**N Siracusano** New phenomena observed in the annular discharge The two hypotheses,

advanced by J J Thomson and Lehmann respectively, to explain the annular discharge observed when the discharge currents of two large Leyden jars excited by a coil or an electric machine are passed through a few coils of copper wire round a highly evacuated glass tube or flask, are discussed The conclusion drawn is that both hypotheses may be accepted, since the conditions of excitation and gas pressure are such as to give rise to the causes assumed by each Various new observations are described —**Remo de Fazi** and **F Pirrone** Studies on indones, new reactions of α ethyl β phenylindone and of α methyl β phenylindone (10) Attempts to prepare diethyldiphenyltruxones by the action of copper on αβ dichloro α ethyl β phenylhydrindone, obtained by passing chlorine into a solution of α ethyl β phenylindone in anhydrous carbon tetrachloride, resulted in the formation of αα[1] diethyl ββ[1] dichloro ββ[1] diphenyldihydrindone and α ethyl b phenylindone —**E Oddone** The depth of activity of the hypocentres of earthquakes and the causes of the latter **M Tirelli** Irreversible change in the viscosity of the eggs of *Bombyx mori* L The experiments described deal with the changes produced in the viscosity of silkworm egg juice with eggs of a pure Chinese race and of a Chinese Italian cross by heating and by treatment with gaseous ammonia —**C Jucci** Pigments of the blood, cocoon and egg of the silkworm —**G Lentati** Study of the primary endocrine tissue of the pancreas of birds **G Mezzadroli** and **E Vareton** Further investigations on the action exerted by a radio oscillator for ultra short waves of 2 3 metres wave length on the germination of seeds and on the growth of plants (1) Ultra short electromagnetic waves always exert a favourable influence on the germination of seeds and on the development of plants, the extent of the action increasing with the nearness of the radio oscillator and, within certain limits, with the intensity of the waves Interposition of a Lakhovsky oscillating circuit over the germinator or plants during the exposure to the waves enhances the effects —**L De Caro** Regulating power of the principal constituents of muscle juice

The Rules of Zoological Nomenclature

AS already announced in NATURE, the International Zoological Congress will meet at Padua next September A week before the Congress opens, the International Commission on Zoological Nomenclature will resume its sittings so as to report to the Congress on numerous cases that have been submitted for its opinion and on certain important proposals that have been under consideration since the last Congress It is useful to remember that this Commission has carried on its work continuously since its appointment in 1895 Even during the War its members were in correspondence, and, though a longer interval than usual elapsed between the Congresses, there was no break of any kind The composition of the Commission of eighteen members has continued subject to the bye laws, according to which members are elected for a term of nine years and one third retire triennially Thus the wisdom of experience is seasoned with new ideas Criticism has been levelled at the constitution of the Commission, but it is difficult to devise any better method Great care is taken that the various branches of systematic zoology and the different parts of the world should be represented A commissioner must be interested in the subject and must have access to a good library, but no attempt is made to seek out the holders of particular opinions

However such an international body be appointed, and with whatever care it weighs the arguments, its decisions cannot please everybody It would be absurd to suppose that all zoologists could agree on these disputed questions Inevitably also there is perennial conflict between the general zoologist and the specialist, between the morphologist and the systematist It seems obvious that the decision must rest with those who are constantly dealing with names and have studied the principles of nomenclature, but since the Congress at Monaco the Commission has accepted fairly the compromise there agreed upon, by which the rules may be suspended when their rigid application would lead to worse confusion

At Budapest, in 1927, the Commission spent several days in attempting to meet the views of many critics No final decision was reached, but certain amendments were suggested in the Commission by way of compromise, and they have to be finally voted on at Padua An account of these and other proposals of later date was recently given by the Secretary of the Commission, Prof C W Stiles, to the International Congress of

Entomology, and is published in its *Transactions* (**4**, pp 622 645) Some of them may be mentioned here

At an early date the Congress refused to receive from the Commission any amendments to the rules that had not received a unanimous vote in Commission Of recent years the view has gained ground, particularly in Europe, that this permitted an obstinate minority (possibly of one) to bar generally desired reforms, and it has been pro posed that any amendments which obtain a majority vote in Commission should be reported to the Congress and decided by it in open meeting This plainly goes too far in the other direction and it is not surprising that the Commission has rejected it twice It is, however, to come up again, and a compromise has been proposed, as follows

"At least all those proposals for amendments to or additions to the International Rules of Zoo logical Nomenclature which have obtained—*first*, a majority of five sixths of the total membership of the Commission of Nomenclature for the time being, and *subsequently*, five sixths of the votes of those present at the meeting of the Commission, shall be the recommendations of the Commission to the Congress"

This has been countered by a proposition that "The stability of the rules is a prime and funda mental principle" Theoretically, most workers will accept this, for constant revision of the rules would be disastrous It is further argued that rules based on a unanimous vote should not be altered except by unanimous vote The practical question seems to be whether a rule which experience has shown to be objectionable should be modified soon or at a later date No doubt impracticable or unwise proposals will be made from time to time, but it is highly improbable that they would ever gain the votes of five sixths of the Commission On the other hand, it does seem probable that any pro posal supported outside the Commission by a large body of working zoologists and inside it by fifteen of its eighteen members would some day gain the suffrages of all the Commissioners Is anything gained by postponing that day ?

Other proposals that fall to be discussed this year concern type designation by elimination, the acceptance of generic names used by non binominal authors, and the change of starting point from Linnæus' 'Systema Naturae", Ed X to Ed XII This last would, if accepted, throw an enormous amount of work accomplished during the past thirty years on to the scrap heap, but its acceptance is in the highest degree unlikely

It is a somewhat curious fact that on all these questions except the last there is an apparent cleavage of opinion between American and European zoologists If one could discover the true reasons for this divergence, one would probably arrive at the best solution of the matters in dispute Some will tell us that the American pack merely comes to heel at the call of Prof Stiles, an absurdity that carries its own refutation to anyone acquainted with American conditions Perhaps one reason is to be found in the mentality that leads citizens of the United States to organise their activities, whether of business or sport, on lines of mechan ical thoroughness manifest in such apparatus as rationalisation, classifications, card indexes, and rules The Englishman, if not the European at large, prefers freedom to over much legislation He is quite as law abiding as any American, and has indeed so high a respect for the law that he will not pass laws unlikely to be obeyed and is ready to reform those that prove harmful

Prof Stiles maintains that, because eighteen (or fewer) people have once unanimously agreed on a rule, that rule should never be altered except by unanimous vote At the outset unanimity was forced on the Commission by the Congress, and it looks as though the Commissioners were conse quently more unanimous in their votes than they were in their opinions, for the sake of getting some thing done Anyone with experience of committees knows how often practical considerations lead him to vote for a proposition with which he does not fully agree If now there is a real demand by zoologists that the power of veto resident in any single commissioner should be taken away, and a five sixths effective majority substituted, is there any good reason why the Commission should not accept this and thus conciliate the opposition ? The further reason given by Prof Stiles is that the rules should be stable in principle and that any reversal would be disastrous With this thesis most zoologists will doubtless agree, though there might not be such general agreement on what is a principle and what is not, and some might claim that a non retroactive change is not a reversal However that may be, it appears highly improb able that when rules have been maintained for thirty years on a unanimous basis, any serious alterations will win the votes of five sixths of the Commission Important as the stability of the rules doubtless is, it is no less important that they should be generally accepted and applied The Commissioners may be so immovable that the flood of zoologists will pass them by

International Trade

Unsolved Problems National and International By John S Hecht Pp 288 (London Jarrolds Publishers (London), Ltd, 1930) 16s net

ON April 25, 1835, the Académie des sciences morales et politiques—one of the five academies comprising the Institut de France in Paris—announced a prize competition, and offered the sum of 3000 francs for the best essay in answer to the following question

"When a nation intends to establish free trade (la liberté du commerce), or to modify its tariff laws, what are the facts which it ought to take into consideration in order to reconcile in the most equitable manner the interests of producers and of consumers?"

Among the competitors was a German engineer, Friedrich List, whose name is among the greatest in the annals of economics, and who, after devouring all the works on political economy he could find in the great Paris bibliothèque, wrote out his essay in feverish haste, working day and night The result was an elaborate treatise on economics which, although it did not win the prize—the prize was not, in fact, won by anybody—formed the basis of his subsequent work on a national system of political economy

The prize was not won, and now after nearly a hundred years it seems that the world still awaits a satisfactory solution of the above problem, although it is now stated in a rather more comprehensive form, and with less emphasis on the distinction between producers and consumers It is a problem which, in so far as its solution appeared to lie in the direction of free trade, has always profoundly interested the scientific world, for, justly or unjustly, the doctrine of free trade has always appeared to have a sounder scientific foundation than any sort of protectionist theories which, on the contrary, appeared to rest on a merely empirical basis, grounded in expediency, self interest, and sheer opportunism Free trade seemed also to have an even higher and nobler origin in or association with that philosophy of freedom and liberty which shone so clearly and strongly in eighteenth century thought, and it is no wonder that it appealed powerfully to both philosopher and scientific worker, and that the most learned body in Europe, nearly a hundred years ago, deemed it not beneath its most serious consideration, but some shadow of doubt is now emerging whether free trade really deserves this rich cloak of aristocratic association whilst protectionism shivers in the rags of empiricism In the most authoritative work yet published on the history of economic doctrines (that of Profs Gide and Rist) it is stated that

"If there is one lesson more than another that emerges from a study of the history of economic doctrines it is the necessity for a more critical spirit and a more watchful attitude, always ready to test any new truths that present themselves, to extend a hearty welcome to every fresh observation or new experience, thus enabling the science to enlarge its scope and gain a deeper significance without sacrificing any of its essential tenets"

One presumes, in passing, that the only real test of new truth is practical experiment, even in the social sciences, that indeed a vast amount of experimentation in the social sphere has been an outstanding feature of the last twenty or thirty years, that such experiment should be continued and extended and the results collected and collated with the utmost possible diligence and mental acumen, and that all real or imaginary association with worn-out theories or philosophy should be broken

This and the above quotation may be said to form the basis of Mr Hecht's new book, which may be strongly recommended for close study by everyone interested in commercial and industrial problems, and who to day is not interested? He says that our chief problems nowadays are naturally of an economic order, and the most pressing of them, because inability to solve it calls for doles with their demoralising influence, is unemployment There is not enough work to go round, which seems strange when one considers that out of every hundred individuals the material desires of ninety nine are unsatisfied Then there are the correlated problems concerning agricultural and industrial depression, the insufficiency of the national dividend and consequent burden of taxation, and the restriction of credit Further, what is the reaction of foreign commerce on the aforesaid problems? Some think that their solution and the prevention of ill-will among nations lies in freer trade and buying in the cheapest market Others are equally convinced that for Great Britain the right policy is safeguarding and buying within the Empire Can these things be put to the test of practical experiment, or must they for ever form the burden of endless argument and exacerbated controversy? Mr Hecht considers that the pivot of all these problems, both national and international, is wages, and it is mainly from the point of view of wages that he seeks, and claims to have found, a solution both of the wages problem or just distribution of wealth, and of the safeguarding problem and abatement of

international discord The French Academy offered a prize of 3000 francs The British nation might well offer a prize of £3,000,000 to anyone finding a satisfactory and practical solution of these weighty and hitherto intractable enigmas

There is not space here to do justice to Mr Hecht's discussion of the wages problem in the first part of his book, and we must confine our attention to a brief examination of the second part, treating of international trade, with special reference to free trade and safeguarding He at least has no respect for free trade because of its affected association with an old and worn out philosophy or pretence at scientific form It does not indeed exist in real life, and is a mere abstraction In regard to Great Britain it would be quite justifiable to say that, so far from being scientific, it is not even correct in its name, and surely it is hopelessly unscientific to make a serious mistake right at the outset in terminology Trade consists in exports as well as imports, and whilst the British export trade is hampered and shackled and overwhelmingly burdened with high tariffs in nearly every market in the world, it cannot, except by a most ridiculous distortion of the truth, be called in any sense of the word free A system merely of free imports is vastly different from free trade as understood by its greatest exponent, Adam Smith, and to seek to uphold such a one sided system under a false name is not science and is morally indefensible

Mr Hecht insists on the profoundly important distinction between complementary imports and competitive imports Forty or fifty years ago the imports into Great Britain were mainly complementary and consisted in those things, largely raw material, which we could not produce ourselves at home But as other nations became more advanced and industrialised the character of our foreign trade underwent a radical change, and our imports became largely competitive Mr Hecht shows that complementary imports decrease production costs and raise wages by economising labour, and by keeping labour and capital employed in those industries where both profits and wages are high He shows further, or certainly makes out a strong case for the contention, that competitive imports on the contrary increase production costs by reducing the efficiency of home industries and the possibility of mass production Moreover, the cost of producing anything depends on another factor, namely, the continuity of demand, or in other words an assured and adequate home market "To expect industrial enterprise," says Mr Hecht, "if an article is to be made at home one day and imported on the morrow is absurd" But foreign competition in the home market is always variable in the absence of tariffs one can be sure that it will be intense, but the degree of intensity cannot be predicted For the same reason the export markets are generally unstable, and little planning ahead for future demand — so essential for minimum costs — is possible Therefore we may conclude that competitive imports involve the loss of what would be a certain and stable home market for what is necessarily an uncertain and unstable foreign market

"Competitive imports destroy the stability of home industries, and cause thereby a twofold increase in production costs For, first, although these imports must be paid for by exports, industrial or commercial instability makes capital unproductive by leaving it standing idle, secondly, industrial or commercial instability makes labour unproductive by provoking unemployment" (See Chaps v and vi in the original)

The author next proceeds to examine a further disastrous effect of unrestricted competitive imports, namely, that of lowering the quality of home industries It is fairly well known by every British manufacturer that the keenest competition from abroad is in those industries where profits and/or wages are high, and where there is the maximum scope for price cutting The ultimate effect of foreign competition, that is, competitive imports, is to drive labour and capital from those higher grade industries into those of lower grade where both profits and wages are lower This degradation in British industry has been going on constantly for the last thirty or forty years, so that to day the leading industries are low grade wherein profits are almost negligible and wages down to a minimum, for example, in coal mining, in many branches of the textile industries, in shipping, and in several others

Britain's three principal exports—coal, textiles, shipping (this latter paying for imports by services)—are low grade in the sense that both wages and profits are very low, whereas German and American exports are the products of high grade industry This is well illustrated by the character of the trade in textiles between Germany and Great Britain in 1913 In that year Great Britain exported to Germany hosiery, lace, cotton gloves, and other highly finished textiles to the value of only £633,776, whereas her imports from Germany in the same class of goods were £4,328,185 Of cotton waste and yarn (low grade semi manufactured textiles), British exports to Germany amounted to £5,662,872,

and her imports from Germany £443,028 This was in 1913, and the position from the British point of view has become much worse since then It shows clearly that Germany is getting more and more of the trade in the higher class highly finished textiles and leaving the lower grade branches, of low wages and lower profits, to Great Britain This change in the *quality* of British industry and British exports is one of the most momentous in the industrial history of the country, and is not sufficiently appreciated in all its implications

A further charge in the indictment of our so called 'free trade', more correctly free or competitive imports, is contained in its effect on agriculture Mr Hecht very truly says that home grown food is our natural food, imported food cannot be so fresh and is liable to deterioration, so that the health and productive power of a people dependent mainly on imported food must suffer Also the import of agricultural produce drives labour from the village into the town "But agriculture is undoubtedly the healthiest industry known to man It breeds a virile race Consequently, competitive imports increase production costs by impairing the salubrity of home industries" It may be that Mr Hecht is not on quite such sure ground here as in other parts of his indictment, but he does make out a strong case for his main contention, that is, that competitive imports lower wages in home industries, and that universal free trade would reduce wages throughout the world, down indeed to the level of the lowest paid labour, such as that of India, China, or Japan

In a chapter showing how the current theory of international trade came to be tolerated, the author comes to the conclusion that that theory is well nigh inexplicable in all its various postulates, including the assumptions that all imports economise labour, that the amount of labour economised is incalculable, that money pays for imports That theory has indeed originated in the same false principles as the current theory of wages, and he quotes Sir William Ashley ("A Retrospect of Free Trade Doctrine") at great length in support of his denunciation thereof The last two chapters in an excellent work, which should be closely studied by everybody, deal with the influence of money on international trade, and with the safeguarding problem In his examination of an exceedingly intricate, difficult, and highly contentious field the author has endeavoured to keep as closely as possible to the actual facts of our present industrial position, and shows, moreover, a fairly comprehensive grasp of the voluminous literature of the subject dealt with, as evidenced by the exhaustive documentation which supports the book It is an invaluable contribution to the elucidation of the vital problems which now seem to involve the very existence of the British nation W G LINN CASS

Preservation of Scenery in the Thames Valley

The Thames Valley from Cricklade to Staines a Survey of its Existing State and some Suggestions for its Future Preservation Prepared by the Earl of Mayo, S D Adshead, and Patrick Abercrombie, with the assistance of W Harding Thompson, for the Thames Valley Branch of the Council for the Preservation of Rural England Pp xvi + 106 + 34 plates + 6 maps (London University of London Press, Ltd, 1929) Limp cloth, 15s net, cloth boards, 21s net

THE publication of this handsome quarto volume with fine type and good paper, admirably illustrated and well provided with specially prepared maps, will serve to mark an epoch in the history of landscape planning Before the Industrial Revolution, the wealthy landowner planned the environment of his mansion so that garden, open pasture of the park, woodland, and arable, combined economic efficiency with pictorial grouping The time has now come when the nation should take control of the countryside and plan its development so as to combine the conditions of economy and beauty

The charms of the Thames side between Cricklade and Staines are described by the authors of this book with a restrained enthusiasm in keeping with the quiet beauty of the country itself, thus predisposing the reader to a sympathetic consideration of the constructive proposals for preservation of beauty under progressive conditions The riverside towns are dealt with in succession, particular attention being given to by pass roads and other means for preserving the charms of the old High Street, and the use and preservation of every ancient bridge is carefully considered The excellent photographs of these monuments remind us of the fact that in the shadowing of its arches an outdoor viaduct excels the beauty of nave or aisle, and that the arches which span a smooth stream excel those of the viaduct because of their etherealised reflection

The most important, and perhaps the most novel, proposals are those relating to the prevention of building on the broad, flat meadows

which lie in the embrace of the river's curve To the unwary visitor, these appear attractive for residence, or at the least for the week end bungalow, but are in fact unfitted for any dwelling place The ground is always waterlogged at a level little below the surface and is in most cases liable to flood, so that the site is unhealthy for the occupant A still more important drawback is the difficulty of providing for disposal of sewage and of preventing contamination of the river It is needful, moreover, that the river should be allowed to spread over these meadows in seasons of heavy rain, thus preventing sudden and excessive rise of level in the lower reaches

When we turn from the hygienic to the æsthetic aspect of the matter we find that it is a requirement of scenic grouping, or 'landscape composition', to keep these broad, flat meadows free from buildings, for they are the foil of riverside towns and wooded bluffs, and also essential to the prospect from the opposite, higher bank, from which we obtain the wider view of the Thames Valley and its background of distant hills

The Council for the Preservation of Rural England has only been in existence for three years, but its influence upon public opinion is already so great that there is every reason to hope that the proposals put forward on behalf of its Thames Valley branch will receive careful and sympathetic consideration VAUGHAN CORNISH

Fossil Brains

Die fossilen Gehirne Von Tilly Edinger Pp 249 (Berlin Julius Springer, 1929) 36 gold marks

THE best results in science have been obtained mostly by combining two hitherto separate branches or methods The author of the work before us is a daughter of the late Prof Ludwig Edinger, who is well known as one of the founders of the comparative anatomy of the brain She grew up, therefore, in a very centre of comparative neurology, and having also studied palæontology from the geological point of view, she joined these two branches in a remarkable manner in *palæo neurology*, which is not an entirely new combination, but has never been practised so thoroughly and methodically The chance to make errors in this field is greater than anywhere else For, as the author acknowledges in the very beginning of her book, a fossil thigh bone is a thigh bone anyhow, but a 'fossil brain' is not a brain at all it is—with a few exceptions—only a natural (petrified) or artificial endocranial cast of a fossil skull By this fact we know more of the central nervous system of many fossil animals than, for example, of their intestines, but to interpret the data with accuracy we must begin by studying in recent animals the relations between the brain and the form of the endocranial cavity, which is in many cases much more spacious than would be necessary to contain the brain only These and other methodical and technical matters are discussed in detail and elucidated with many illustrations in the general part (pp 9-100) of the book

Dr Edinger has tried to write a clear and instructive book for neurologists, for whom so many names of geological periods and fossil animals are mere 'words', as well as for palæontologists not versed in the neurological 'jargon', and in this she has been successful

The other part of the book is a copiously illustrated critical compilation (classified according to the zoological system) of all that is known about the central nervous system of fossil vertebrates, and it is more than a compilation only, for the author, guided by her great experience on the subject, often gives her own interpretation of the facts The alphabetical bibliography (250 entries !) has the practical feature that not only are the titles cited, but also with every article a brief mention is made of what it contains referring to the subject in question

In conclusion, some of the problems of general interest dealt with in the chapters may be mentioned Marsh's 'law' suggesting that the species that proved to be the 'fittest to survive' had comparatively larger brains than the extinct forms, is not generally confirmed Technical masterpieces of palæoneurology are the reconstructions of the endocranial cavity with all canals and openings in fossil fishes, made by Stensiö It is confirmed that some of the giant forms among fossil animals had small brains, but a relatively giant hypophysis The sacral dilatation of the spinal canal in *Stegosaurus* is discussed in detail The brain of the flying reptiles (Rhamphorhynchoidea and Pterodactyloidea) had many bird-like features, while the brain of the contemporary *Archæopteryx* was still more of the reptile type The typical form of the bird's brain seems to be in connexion with the function of flying Like other organs also, the fossil brains make it clear that both birds and mammals have developed gradually from reptiles, this evolution is partly a relative increase of the fore brain The brains of fossil Anthropoidea are described in a special chapter

P J VAN DER FEEN, JR

Our Bookshelf

Reports of the Progress of Applied Chemistry Issued by the Society of Chemical Industry Vol 14, 1929 Pp 775 (London Society of Chemical Industry, 1930) 7s 6d to Members, 12s 6d to non Members

The publication of a new volume of the annual reports of the progress of applied chemistry recalls the strange fact that there are still some industrial chemists who have never used, never even heard of, this excellent review Chemists are usually busy people, and busy people cannot be expected to read extensively the literature of those parts of the science with which they are not immediately concerned They ought to do so, they admit, but can find neither time nor capacity for the enormous task Nowadays, a chemist who claims to be well informed is not necessarily a voracious reader of original papers, even in his own language, but is often one who, at least for his non essential study, relies on records such as that under review, afterwards using them for the selection of the relevant literature to be consulted How often do we now read not to acquire information but to discover where it is to be found! Moreover, only the favoured few can afford to maintain a reasonably adequate chemical library, most of us are content, so far as journals are concerned, to keep the annual reports on pure and applied chemistry at hand and the corresponding abstracts within reach By so doing we can at least rely on being kept in close touch with the development and application of chemical science

The present volume covers the same ground as its immediate predecessor with the exception of explosives, in which domain the survey is biennial The chapters on general, plant, and machinery (R Edgeworth Johnstone), fuel (J G King), refractories, ceramics, and cements (W C Hancock), iron and steel (C O Bannister), india rubber (H P Stevens and W H Stevens), leather and glue (D Woodroffe), foods (L H Lampitt), sanitation and water purification (J H Coste), fine chemicals, medicinal substances, and essential oils (E Stedman), and photographic materials and processes (F M Hamer) have been entrusted to authors who were not concerned in the preparation of last year's report, the remainder of the twenty four chapters have been contributed by the same authors as in 1929, either alone or in collaboration A A E

Laboratory Guide to Vertebrate Dissection for Students of Anatomy By Dr A B Appleton Pp xix + 152 (Cambridge At the University Press, 1929) 6s net

As its title indicates, this is a book for use in a practical comparative anatomy course It is intended for a somewhat unusual class of student, and consequently its contents, outlook, and method of treatment are unlike those of the standard texts in this subject As stated in the preface, it is assumed that the student has already done a course in elementary zoology, including the usual vertebrate types, and has also examined in more detail a mammal Unless this mammal were man, a number of comparisons in the book would be missed To obtain full benefit from it the student should obviously have taken the preliminary medical studies, including a fair amount of human anatomy This is not meant to imply that the student of advanced zoology cannot get many useful hints and fresh points of view from its pages, he undoubtedly can The types, treated in a series of regional dissections, are the lamprey, the dogfish (*Squalus*), *Necturus*, the lizard, and the dog As it is intended for assistance in dissection, information regarding osteology and the details of the central nervous system have been purposely omitted and, conversely, the muscles are treated somewhat more fully than is customary

In applying, so far as possible, the International (Basel Nomina Anatomica) Code of Nomenclature, the author has set a commendable example that might be followed with advantage by other works in comparative anatomy On p 28 it is stated that from the union of the pre and post trematic arteries dorsal of the first gill cleft two vessels arise "the first efferent branchial artery and the internal carotid artery (lateral dorsal aorta)" The former is better termed the first epibranchial and the latter is the hyoidean epibranchial—it is certainly not the internal carotid or the lateral dorsal aorta, as a glance at Scammon's reconstruction of these vessels in the embryo would show

Atmospheric Corrosion of Metals Third (Experimental) Report to the Atmospheric Corrosion Research Committee (British Non Ferrous Metals Research Association) A Discussion held by the Faraday Society, 23rd May 1929 Pp 173 252 + 475 502 (London The Faraday Society, 1929) 5s 6d net

Previous reports to the Atmospheric Corrosion Committee have been concerned with laboratory experiments, and most interesting results have been obtained regarding the part played by an initial film of tarnish in determining the subsequent course of corrosion, especially of copper and its alloys In the present state of our knowledge of corrosion, such carefully designed and executed experiments are of far greater value than a mere accumulation of empirical data, the number of which is already far too great It was necessary, however, to confirm the laboratory results by field tests, and the latest report describes a systematic series of such tests, utilising the conclusions of the earlier work

As is usual in field tests of corrosion, the results are by no means simple, and in fact the total amount of corrosion was so small as to suggest that typical non ferrous metals should last for very long periods, even in industrial atmospheres Much depends on the amount of exposure to rain, as the corrosion when the soluble products are continually removed may take a quite different course from that taken when the products accumulate as a crust For wire specimens, the change of electrical resistance gives a fair measure of the

extent of the corrosion The effect of humidity and of the formation of deliquescent products is clearly brought out, and the results are of undoubted value In practice, local attack due to the concentration of the effects on a small portion of the exposed surface must play a large part in determining the life of a material, general corrosion having little effect

La diffusion moléculaire de la lumière Par Jean Cabannes, avec la collaboration d'Yves Rocard (Recueil des Conférences Rapports de Documentation sur la Physique, Vol 16) Pp viii + 326 (Paris Les Presses Universitaires de France, 1929) 65 francs

THE scattering of light by small particles observed by Tyndall was studied exhaustively by Lord Rayleigh, who showed in 1871 that each particle, assuming its dimensions small in comparison with the wave length, sets up a secondary disturbance which travels in all directions In 1899, Rayleigh concluded that the blue colour of the sky could be accounted for by the scattering of light by molecules of the atmosphere In the book under notice, the author seeks to establish a coherent theory of the diffusion of light in the interior of a fluid on the assumption that the incident wave excites in each molecule a movement proportional to the field, these little induced doublets vibrate with the frequency of the exciting wave and in their turn radiate diffused light

Although the idea of such molecular diffusion is comparatively modern, we are confronted to day with an immense field of experimental and theoretical investigation The author has accordingly confined his attention almost entirely to the diffusion of ordinary light in the interior of pure transparent fluids, and only in an appendix does he refer to the Raman effect He has carried out a critical examination of the experimental results and also of the theoretical formulæ In the latter part of this work he has had the assistance of M Rocard, who contributes two chapters dealing with the character of the diffused light as the critical point is approached, and with the study of the 'critical opalescence' The volume should be of great service to future investigators

Discoveries and Inventions of the Twentieth Century By Edward Cressy Third edition, revised and enlarged Pp xxi + 476 + 177 plates (London George Routledge and Sons, Ltd, New York E P Dutton and Co, 1930) 12s 6d net

As the successor to Routledge's "Discoveries and Inventions of the Nineteenth Century", Mr Cressy's book has enjoyed considerable popularity First published in 1914, a second edition appeared in 1922, and to this further matter has now been added, and the number of illustrations has been increased No one, perhaps, realises the difficulty of attempting to deal with modern discoveries and inventions in one volume, or of keeping such a volume up to date, more than the author himself

Mr Cressy's book is written in the first place for the non technical reader, but we imagine many engaged in scientific work and engineering will find its chapters of great interest The ground covered is mainly that of power generation and transmission, transport by land and sea and air, communication by electricity, and such developments of chemistry and physics as may be included under the titles—soils and crops, the borderland of modern chemistry, applications of photography, radium, electricity, and matter Other subjects to which chapters are devoted are the electric furnace and refrigeration

Included in the text are many diagrams and photographs, the former being by far the more valuable to those wishing to know the why and wherefore Whether the non technical reader can understand the principle of the gyroscopic compass or the Ljungstrom steam turbine from the drawings given we are doubtful In the chapter on gas, petrol and oil engines, the Fullagar engine is unfortunately shown upside down, while the statement that the internal combustion engine used in ships is not reversible needs correcting

The Conduction of Electricity through Gases By Dr K G Emeléus (Methuen's Monographs on Physical Subjects) Pp x + 94 (London Methuen and Co, Ltd, 1929) 2s 6d net

THE phenomena of the electric discharge in gases are very striking in character and appeal strongly to those interested in physics Besides, they have received numerous technical applications But the subject is in reality complicated from an experimental point of view and is one which from a theoretical point of view is incompletely understood The nature of the discharge is due to the occurrence of many elementary processes (the most important of which are ion formation and the excitation of light) linked together in a way which is obscure Dr Emeléus has presented fairly the present stage of development of the subject, and, therefore, we welcome his little work even though we may regret that he has not had more space to develop his views, for then the book would have been more readable as well as more informative But in compensation it is very cheap, and since, within its limits, it is extremely well written, we have no hesitation in recommending it H W B SKINNER

The National Benzole Association Standard Specifications for Benzole and Allied Products, 1929 Pp xiii + 145 (London National Benzole Association, 1929) 6s net

MULTIPLICITY of standard processes has been avoided by the whole hearted adoption by the National Benzole Association of those portions of the "Standard Methods for Testing Tar and its Products" (see NATURE, April 26, p 631) appropriate to the examination of benzene, toluene, xylene, and naphtha In addition, there are given for various commercial grades of these materials, fourteen specifications, applicable only when the particular methods described are used Allowance is made for the addition of any further specifications or methods that may be made from time to time B A E

Letters to the Editor

Reflection of Positive Ions by Crystals

FURTHER experiments on the reflection of hydrogen positive rays from crystals, similar to those described in NATURE for Jan. 11, have shown that the phenomenon is more complex than might have been expected. More than a hundred photographs showing reflected rays have been obtained under various conditions, and they show several features of interest. Great differences have been found in the reflecting powers of different samples of calcite. Two were found that gave strong reflected rays when the glancing angle was less than two degrees. The images obtained on Schumann plates placed at right angles to the beam may be properly termed reflection patterns, as they show considerable complexity, vary in a regular manner with the angle of incidence, and can be reproduced at will with the same setting of the crystal and speed of the rays. Six other calcite crystals gave reflection patterns containing fewer lines or lines on a fogged background. Reflected rays were also observed with a diamond which was kindly loaned by Dr. D. Cooksey. A natural cleavage face of this diamond had been used in experiments on the reflection of gamma rays. A highly polished face gave indistinct patterns on a fogged background. Clear lines were obtained from two other faces, one of which was the natural cleavage face, and the other a face that had been cut and appeared rough due to saw marks. No reflected rays were found in a few trials with rock salt, galena, and magnetite.

The strongest parts of the patterns are produced by rays that have energies corresponding to more than six thousand volts. Slower rays may be present in the original bundle, as shown by a positive ray analysis, but they are not reflected so strongly as the faster rays. With a low potential on the discharge tube the reflection pattern lacks certain of the parts that appear with high potentials. A positive ray analysis of the ions reflected from one of the calcite crystals showed that in addition to the hydrogen atoms previously reported, all the positive ions in the original bundle are present in the reflection patterns, namely, hydrogen molecules, triatomic hydrogen molecules, and heavier ions that are probably oxygen atoms. With the present resolution, the various ions are superimposed in the streaks or lines formed by the reflected rays of various velocities.

The dependence of the angle of deviation by the crystal on the energy of an ion, rules out the possibility of ascribing the reflection to the deviation of particles by electrostatic forces, which would require the reflected rays of various velocities to lie in a plane, and to have angles of deviation inversely proportional to the energies of the particles. In most cases the reflected rays of different velocities do not lie in planes, as they give curved images on the plate, and in the cases where a straight line is formed the deviation is not inversely proportional to the energy but is a linear function of the reciprocal of the velocity. Charges would not be expected to accumulate on the crystal because of the secondary electrons liberated by the bombardment of metal parts near it, and its uncharged condition is shown by the fact that those rays which just pass over the crystal without hitting it are undeflected. The small penetration of the ions into matter, as compared with electrons of the same equivalent wave length, suggests that energy changes at the surface or inside the crystal will have to be taken into account in a complete theory. The important factor in determining the angles may be a quantity analogous to a refractive index which would depend on the energy of the ion and its alterations.

Small changes in the angle at which the incident rays hit the crystal produce a regular series of changes in the direction of the deflected rays. At nearly grazing incidence on one of the calcite crystals with the rays parallel to an edge of the cleavage rhomb, there was a fan shaped arrangement of the reflected rays in eight or more radial lines of different intensities. As the angle was made steeper, the lines formed by the reflected rays of various velocities shifted towards the normal to the crystal surface and became curved, the intensities altered, and new curved lines appeared at the sides, making the patterns more complex and more symmetrical. This change was produced by an increase of only one degree. With a second calcite crystal which was turned so that, at grazing incidence the rays made an angle of about fifteen degrees with an edge of the cleavage rhomb, clear patterns were obtained which had an unsymmetrical character. These patterns, as well as those from the diamond, also changed in a regular manner with small increases in the angle of incidence. The dependence of the angles of reflection on the angle of incidence and on the velocity of the rays suggests very strongly that a theory of the phenomenon will have to contain other elements besides particles and the forces exerted on them by electric and magnetic fields.

A Point in the Theory of 'Critical Illumination' in the Microscope

IT is extremely difficult to give any general theory of the formation of the image in the microscope, inasmuch as the action differs with every different object and with the arrangement of the illumination. On the other hand, it is possible to give a satisfactory account of particular cases which throw light on the various 'simplifications' which have from time to time been put forward. Modern views are represented in a recent discussion on the Abbe theory (*Jour. Royal Mic. Soc.*, **49**, pp. 123-142 and 228-264, 1929).

A case which allows of simple treatment is that in which the illuminating system is imagined to be projecting the image of an axial point source symmetrically into the object plane. It may be assumed that the illuminating lens is free from aberration and that it has a rectangular aperture.

The distribution of amplitude in the plane then follows the usual law

$$a = \text{constant} \times \frac{\sin u}{u},$$

which is plotted in the thick curve of Fig. 1. Note that the amplitude may change sign, but the phase remains constant. The broken curve shows the relative intensity, represented by the square of the above function. As is well known, the central maximum is very large in comparison with the lateral maxima, which rapidly decrease in intensity. Similar results are found for the distribution of amplitude and intensity along the diameter of the 'Airy disc' characteristic of a circular aperture.

If A_i is the 'numerical aperture' of the illuminating

cone, the distance h between the central maximum and the first dark minimum ($u=\pi$) is given by

$$h=\frac{0\cdot 5\lambda}{A_t}$$

We may select a case where a grating, typified by a row of very small apertures, lies symmetrically in the

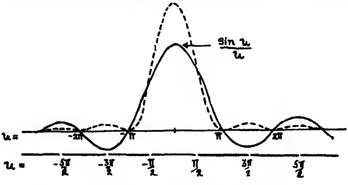

FIG 1 —Values of (sin u)/u, full curve, and (sin u)²/u², broken curve

object plane Then, selecting the spacing of these apertures as distant from the axis on each side by the intervals corresponding to

$$u=\pi/2,\quad 3\pi/2,\quad 5\pi/2,\ \text{etc},$$

it will appear that the amplitudes of the portions of the illuminating interference pattern exposed by the apertures are proportional to

$$2/\pi,\quad -2/3\pi,\quad 2/5\pi,\ \text{etc},$$

on each side

Consider now the central pair of apertures If each aperture is very small, the amplitude of the vibrations diffracted into various directions by one aperture will be fairly uniform The amplitude effect of the two in a direction taken in an axial plane containing the row of apertures and at an angle θ with the normal to the 'grating' will be

$$\text{amp} = 2a_1 \cos\frac{\pi x \sin\theta}{\lambda},$$

where a_1 is the amplitude due to one acting singly, and x is the spacing

The effect of the second pair is $2a_2\cos\dfrac{3\pi x\sin\theta}{\lambda}$

Thus the series representing the effect of the whole row becomes one of the type

$$f(\phi)=\frac{4}{\pi}\left(\cos\phi-\frac{\cos 3\phi}{3}+\frac{\cos 5\phi}{5},\ \text{etc}\qquad\right),$$

which is at once recognised as the Fourier expansion of 'unity'

The resultant effect of the series is seen in the distribution of amplitude in the back focal surface of the objective of the microscope, which follows the Fourier graph, Fig 2, in which the amplitude changes suddenly from plus one to minus one at the values of ϕ given by $-\pi/2$, $\pi/2$, $3\pi/2$, etc The sharpness of the transition is determined by the number of terms in the series, in our case by the number of lines in the grating free to transmit light, not by the number which are visibly illuminated

The regions of constant amplitude with their sharp boundaries correspond to the (touching) diffraction 'images', of the condenser pupil formed by the objective, and if the light is unrestricted, the full resolving power, proportional to the number of elements, is thus seen to be valid although only one or two of the central elements are illuminated in any marked relative intensity

I have chosen one of the simplest possible cases to deal with above, but the discussion can be extended to the more general cases of gratings disposed unsymmetrically to the illuminating 'pattern', and hence to gratings with finite apertures In all cases which I have examined so far, the sharply bounded diffraction images appear Therefore the idea underlying the so called critical illumination of the microscopist, that is, that the sharply focused condenser or illuminator destroys the effective coherence relations between the different parts of the object plane, is somewhat fallacious Of course the extension to the practical case involves the illumination by a source of finite area, and an indefinite number of overlapping Airy discs appear in the object plane, so that the discussion of the above type of coherence can often be short circuited (as can be shown in certain cases) in favour of a shortened 'equivalence principle' However, the fundamental features of the optical action in such cases is very generally misunderstood, and many physicists have maintained that the resolving power of the grating would be greatly diminished in such a case as the above in spite of Huygens' principle Whereas the usual 'Abbe theory' contemplates phase relations only between sets of homologous points or lines, the actual process involves phase relations over definite areas The discussion of the consequences of these ideas is outside the scope of a short letter

In order to test these conclusions practically, I have removed the eyepiece of a spectrometer and mounted a piece of process screen with about 200 lines to the

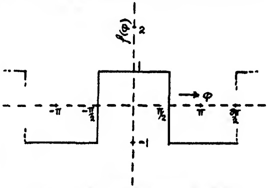

FIG 2 —Fourier expansion of unity (cosine series)

inch in the plane of the spectrum, so that the lines of the grating are parallel to the monochromatic slit image, which is carefully focused in the 'grating' It is not difficult to ensure that not more than one grating element is appreciably illuminated In spite of this the grating is found to produce sharp diffraction images of the aperture of the telescope objective of the instrument An interesting variation is to use the whole spectrum so that every element is apparently illuminated by a different wave length The diffraction, of course, persists

In view of the importance of such considerations in the theory of the microscope, I hope to discuss them more fully elsewhere, and I may add that Mr G F Rose has performed a number of very interesting experiments confirming the principle, which he will also describe

Atmospheric Light Columns from Artificial Lights

THE light columns observed by Mr Currie (NATURE, April 5, p 526), though rather unusual phenomena, have been described previously Once in France and twice in Italy, during the War, I noticed that gun flashes at distances of the order of 15 kilometres appeared as narrow vertical streaks of light centred about 10° 15° above the horizon The occasion in France (Nov 6, 1916) was a most striking one, a note giving the details was published after the War in the *Quar Jour Roy Met Soc*, 45, pp 366 368 (1919) About 9 30 P M on that evening there were visible, in addition, parts of a lunar halo of 22°, a horizontal circle or mock moon ring, and a halo of 90° During the remainder of the evening continual gun flashes produced a weird and unnatural effect as of vertical slits opening and closing suddenly in a dark curtain with a fiery background Later in the same evening a still more remarkable spectacle was presented in that, as a result of enemy action, a large ammunition depot, some 15 km distant from the point where I was stationed, was set on fire The fire (or fires) appeared also as great vertical streaks in the sky, with a dark patch at their centre, the altitude of this dark centre, measured by theodolite, being 32½°

The meteorological situation at the time was that northern France lay under the warm front of an advancing depression, and the sky by this time (11 P M) was overcast with thin alto stratus cloud, deteriorating, through which the moon still shone dimly The optical phenomena produced on this evening by the coincidence of a modern bombardment and a great ammunition fire with the peculiar meteoro logical and optical situation which produces mock moons, etc, have possibly seldom been equalled in history Even in less sensational form, the pheno menon of vertical light columns from artificial lights is apparently seldom seen in western Europe, at least, even knowing of its existence, I have not often seen it

Again, Prof Carl Stormer states (in *Geof Pub*, vol 4, No 7, pp 57 58) that he saw "a singular atmospheric optical phenomenon", near Oslo on Feb 5, 1922, when spectroscopic examination enabled a column of red light to be distinguished as not being an auroral ray It was verified later that in this case the fire had been 6 km distant It is remarked that there was diffuse thin cloud through which one could distinguish the stars, and that this cloud must have consisted of ice crystals and have been at a height of about 3000 metres Prof Störmer told me recently that he has not on any other occasion seen such a phenomenon

A H R GOLDIE

Edinburgh, April 10

MR HUGH NICOL's explanation (NATURE, May 3, p 671) of atmospheric light columns from artificial lights is not merely an extension of mine but an alternative My explanation, the orthodox one, is that the columns are due to the *reflection* of light from laminar crystals, his suggestion is that the columns are due to *diffraction* by laminar or acicular particles

I do not think the diffraction hypothesis can be accepted The laminar crystals which are in the majority when phenomena like sun pillars occur are not microscopic objects The diameters of flat crystals without rays were measured by Dobrowolski He found, for example, that at $-6\ 3°$ C the average diameter was 1 7 mm The cloud particles which pro duce diffraction phenomena, coronæ, are much smaller, having diameters of the order 0 02 mm

The most satisfactory demonstration that reflection does take place from crystals with horizontal surfaces comes from aeronautical observations It some times happens that the aeronaut flying over a cloud sees on the cloud a white patch, the under sun When he comes to a break in the cloud and catches a glimpse of a sheet of calm water below, he realises that the direction of the brightest part of the under sun is just that of the image of the sun in the water

As we are obliged to admit the effectiveness of re flection in this case, there is no need to doubt that the same cause is operative in the other

Telosynapsis or Structural Hybridity in *Œnothera*?

IN a recent article[1] I have put forward a hypo thesis which I consider provides an explanation in terms of segmental interchange and parasynapsis of (i) the occurrence of ring formation in *Œnothera*, (ii) its inheritance on selfing and crossing, and (iii) the occurrence of mutant forms differing in properties of ring formation from their parents These seem to be the essential requirements of a working hypothesis expressing the relationship of *Œnothera* with other plants and animals Further, the premises on which the hypothesis is based have been defined very fully in later articles[2 3 4, 5]

Two of Prof Gates's pupils, Miss Sheffield[6] and Mr Catcheside,[7] have defended his earlier views and criticised this hypothesis on general grounds, without, however, providing any evidence that the hypothesis is incompatible with earlier observations Their objections are directed against my first paper and would, I feel, be removed by a study of the theoretical principles enunciated with some precision and a great amount of detail in the later ones[2, 3 4, 5] which they do not quote It seems superfluous to define these principles again, for there is little to add and nothing to take away

Catcheside,[7] however, has also made a new observa tion, namely, that a ring of 21 chromosomes is formed in a triploid plant, this he concludes "com pletely disposes of the hypothesis of segmental inter change, adapted (*sic*) by Darlington as a basis for parasynapsis in *Œnothera*" Mr Catcheside has been good enough to show me his preparations The critical structures seemed to me susceptible of being interpreted, not as a ring of 21 chromosomes, but as consisting of various configurations of the kind observed by Håkanssen in his account of triploid *Œnothera*[8] Thus the associations I made out were the following (i) unpaired chromosomes, (ii) rod pairs, united at one end, (iii) ring pairs, united at both ends, (iv) chains of three and of four chromo somes, (v) branched chains of chromosomes (with triple union), (vi) ring pairs associated (by a triple union) with one end of a third chromosome Mr Catcheside has given a formula, based on my hypo thesis, with which these types agree

In view of the difficulty of interpretation of dia kinesis figures in triploid *Œnothera* (cf Catcheside's figures 35 and 36), I think the novel conclusion that he has arrived at is a little precipitate Earlier workers on triploid *Œnothera* have often hesitated to come to any decisive conclusion with regard to the delicate question of the association of the chromo somes Gates,[9] for example, has contented himself with saying that "the chromosomes are scattered for a considerable distance along the long axis of the spindle", and later[10] that the 21 chromosomes are "somewhat scattered along the spindle as is usual in many Œnotheras" These difficulties led Gates to

conclude[9] "that there is usually no metaphase, strictly speaking"

P S—Since writing the above I have received a paper by two of the leading authorities on this subject in the United States[11] who "have compared the chromosomal phenomena in *Datura* and *Œnothera* and have shown that segmental interchange is a possible basis of circle formation in both genera" Further, these workers have been able to determine the type of configuration that would be shown by a hybrid, from a knowledge of the pairing properties of its parents' chromosomes and the genetical properties of their characters In four cases tested these determinations (one of them a prediction) were shown by observation to be correct

Those who are familiar with the sterile speculations prompted by the theory of telosynapsis will notice a welcome change in the close reasoning now being profitably applied to the chromosome analysis of *Œnothera* C D DARLINGTON

The Integuments of Whales

IN whales the integuments may be supposed to serve a double or treble purpose the outer layers—the epidermis and the pars papillaris of the dermis or cutis vera protecting the underlying parts, and the deeper—the thick and oily pars reticulata or 'blubber' preventing the loss of heat, and at the same time diminishing the specific gravity of the body and reducing its tendency to sink

In the Greenland whale (? also in the Atlantic whale) the epidermis is thicker than in the 'fin whales', and in the Delphinapteridæ (that is, in the narwhal and white whale) it is thicker, although not to the same extent, than in other 'toothed whales' Moreover in the Greenland whale and in the Delphinapteridæ a pars papillaris which is tough and does not yield oil is present, a condition not met with in the 'fin whales' and in many of the toothed whales'

Are the integuments thicker in the calf than in the adult ? The answer appears to be in the affirmative the epidermis in the young sperm whale is $\frac{3}{8}$ in in thickness against $\frac{1}{8}$ in in the adult, according to Beale, and in the calf of the Greenland whale nearly 2 in against about half that thickness in the adult, according to Scoresby

An epidermis 2 in thick is remarkable, but Scoresby makes the same statement in his "Journal of a Voyage to the Greenland Sea in 1822", and in the log book of his 1811 voyage preserved in the Whitby Museum

In the blue fine whale (*B Sibbaldi*) the blubber is known to be thin and imperfectly formed at birth (see Turner, *Trans Roy Soc Edin*, vol 26) Assuming that this is also the case in the 'right whales', might not the great thickness of the epidermis in the calf of the Greenland whale be a protection against the coldness of the Arctic waters until the blubber has reached its normal character and thickness ?

As mentioned in Buckland's "Notes and Jottings", p 352, and recently by Sir Sidney Harmer (see NATURE, Feb 22, p 286), the 'inner skin' or pars papillaris of the narwhal and white whale were at one time used in making leather, but, so far as I know, the corresponding layer of the skin of the Greenland whale, although tough and $\frac{1}{4}$ in thick, according to Scoresby, was never put to a similar purpose The whalers looked on it as valueless and threw it overboard together with the thick 'black skin' or epidermis attached to it Not so the Eskimo, they held it in high esteem as an article of diet 'Maktuk', the Eskimo name for the rejected part of the whale's integument, is, according to Low ("Cruise of the *Neptune*", p 261), usually eaten boiled "when cooked it has the appearance of thick black indiarubber and is soft and gelatinous while its flavour approaches that of the clam" The corresponding parts of the narwhal and white whale were cooked and eaten in the same way ROBERT W GRAY

Search for an Inactive Isotope of the Element 84 (Polonium)

THE elements 81 (thallium), 82 (lead), and 83 (bismuth) have both radioactive and inactive isotopes, whereas the elements 84 92 are only known in an active form Several attempts have been made to find inactive isotopes of the latter elements Aston, using his mass spectrograph, tried to discover a stable isotope of radon in the atmosphere, and Hahn made extensive researches to find an inactive isotope of radium All these attempts failed

We have recently tried to extend the series of inactive elements by searching for an inactive isotope of the element 84 (polonium), which follows bismuth Through the work of the discoverer of this element, Mme Curie, and her co workers, as well as of Marckwald and of many others the chemical properties of polonium were found to be intermediate between those of bismuth and tellurium Hence it is obvious that if a stable isotope exists, it must be associated in Nature with tellurium or bismuth

We looked for the elements 84, therefore, in the following tellurium and bismuth minerals Hessite, calaverite, nagyagite, tetradymite, and bismuth glance as well as native bismuth The minerals were dissolved, and a known amount of polonium added as radioactive indicator On removal of the polonium from the solution, it was to be assumed that any isotope present in the solution would accompany the active polonium By special methods devised for the purpose, it was possible to regain the added polonium electrolytically on molybdenum electrodes, the deposit weighing only about 1/10 mgm X ray investigations, carried out by the secondary ray method to avoid the possible volatilisation of the substance under the action of the cathode rays, have shown that the deposit cannot contain more than 1/2 per mille of the element looked for The X ray line searched for was polonium $L\alpha_1$, the wave length of which was calculated from Moseley's law to be 1111 X U All the lines on the plate could be identified as belonging to lead, bismuth, silver, mercury, or tungsten As we started with about 400 grams of each of the minerals mentioned, 1 gm of each mineral cannot contain more than 10^{-7} gm of the element in question This negative result is in agreement with generalisations arrived at by Dr A S Russell

There is thus very little hope of finding an inactive polonium isotope, or of extending the series of radioactive elements which now exists beyond 83 (bismuth)

The Oldest Record of a Slug

MISS ALICE MACKIE, writing from Egypt, sends me a photograph showing a couple of slugs represented on a wall at Karnak (Fig 1) These figures are of course well known to Egyptologists, but probably not to malacologists They appear to represent the species *Veronicella nilotica* (Cockerell, *Nautilus*, January 1910, p 108), which was found by the Nile above Khartoum In my original account I could only give the coloration as shown by alcoholic material Mrs G B

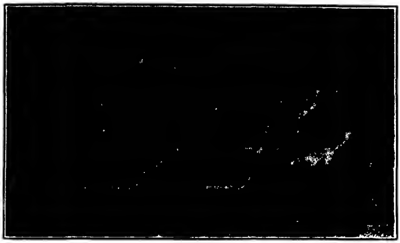

FIG 1

Longstaff found a specimen among papyrus on the river bank at Hillet al Nuwer, an islet on the Bahr el Gebel She noted that the living animal was very dark grey above, beneath dirty yellow turning to deeper yellow anteriorly [1] This agrees sufficiently with the Luxor figures, which are shown to be dark above and pale below As this is the only slug of the kind known from this region the identity is reasonably certain

Polarisierte und gerichtete Röntgenstrahlung aus einem Kristall

DURCH mehrere experimentelle Untersuchungen habe ich festgestellt, dass die Atome der Elemente Wasserstoff und Helium eine ausgezeichnete Achse besitzen, in Bezug auf welche die Gleichgewichtslagen ihrer Elektronen angeordnet sind Auf Grund spektraler Analogie kann man folgern, dass auch bei den schweren Elementen die Elektronen an der Atomoberfläche in Bezug auf eine ausgezeichnete Achse angeordnet sind

Analog sind im Innern und auf dem Grunde der Elektronenhulle der schweren Atome die Elektronen in Bezug auf eine ausgezeichnete Achse angeordnet Dies lässt sich aus einer Erscheinung folgern, welche ich kurzlich aufgefunden habe, es ist die Erscheinung der Polarisation und der gerichteten Intensitätsverteilung der K Strahlung eines Elements aus einem Kristall Die sekundäre K Strahlung des Brom Atoms, welche infolge der Absorption primärer Röntgenstrahlung von monoklinen γ, γ Dibromanthrazenkristallen emittiert wird, zeigt namlich folgende Eigenschaften in Bezug auf die Achse, welche senkrecht zur Symmetrieebene steht, ist in einer Richtung, welche senkrecht auf dieser Achse steht, die Intensitat der sekundaren K Strahlung der Bromatome des Kristalls grosser als in einer Richtung von kleinem Winkel gegen jene Achse, ausserdem ist diese Strahlung der Bromatome zum Teil in der Weise polarisiert, dass die Intensitat der elektrisch parallel jener Achse schwingenden Strahlung bis zu 20 per cent grosser als die Intensität der senkrecht dazu schwingenden Strahlung ist

Aus diesen Eigenschaften der K Strahlung der Bromatome aus Dibromanthrazen lassen sich folgende Schlusse ziehen 1 die Achsen der chemischen Molekule in dem Dibromanthrazenkristall liegen parallel zu einander, 2 die Valenzachsen der Bromatome in diesem Kristall sind einander parallel, 3 die Elektronen der untersten und der nachsthöheren Schale des Bromatoms, welchen die K Strahlung zugeordnet ist, besitzen in Bezug auf eine ausgezeichnete Achse bestimmte Lagen

Ein ausfuhrlicher Bericht uber die vorstehende Untersuchung wird voraussichtlich in den *Annalen der Physik* erscheinen

The Ancestry of Man

THE theory I have been advancing during the last two years that man is not descended from the apes, but from a primitive common anthropoid stock which gave rise to the apes as well as to our own direct ancestors, has gradually come about from the intensive study of fossil man the world over as well as from our recent and more extended knowledge of the anatomy and the habits of the apes This new knowledge reveals data entirely unknown to Darwin, and he to day would be among the first to grasp the new outlook and give it his unbiased consideration I regret to find that advanced and entirely unauthorised reports of my presidential address before the American Association for the Advancement of Science at Des Moines were interpreted as disloyal to Darwin s theory of the descent of man More extended knowledge of the data on which the new point of view is founded will cause such criticism to subside, as disloyalty to the main features of Darwin s theory of the descent of man is unthinkable

It seems that in human palæontology new ideas of time and space, as well as of heredity and of the principles of descent or phylogeny, are compelling us to recast or reconsider all the older ideas to which we fell heir at the close of the nineteenth century I regret that pressure of other work compels me to postpone the assembling of fresh facts and the meeting of many of the arguments which are now being advanced by several authorities for the older point of view Like all other questions of descent, the problem of human ancestry can only be settled by fresh palæontological discovery In view of the fact that anthropoid ape remains are very rare and that primitive human remains are still more rare, we may have to wait for several decades before the fortunate discovery is made The ancestors of man were the most clever of all animals and, therefore, the first to avoid natural burial and fossilisation

Scattering of X-rays by bound Electrons

IN 1923, Compton gave a theory with experimental verifications of scattering of hard X rays by free electrons, and in a subsequent paper he considered theoretically the case of modification of radiation scattered by bound electrons (Compton "X rays and Electrons", p 286) in which the latter may be removed from one orbit to the other Recently, I have observed that a part of the monochromatic X rays in passing through carbon undergoes a change in frequency and appears on the longer wave length side of the primary radiation Copper $K\alpha$ radiation was allowed to pass through carbon soot and the transmitted radiation was analysed by a calcite crystal fitted up in a Siegbahn spectrograph A current of 8 m a was passed through the X ray tube at a peak voltage of 28 k v In addition to the original copper $K\alpha$ radiations and other lines in the tungsten L series, a new diffuse broad line of wave length 1592 X U ($\nu/R = 572$) appeared on the photographic plate This new line appears to have a more or less sharp edge on the short wave length side The wave length of this line was compared with those of other lines the presence of which might be expected from the X ray tube excited under the given condition and was found not to coincide with any one of them The time of exposure was varied from 8 to 14 hours in different cases and all of them showed the same effect

The origin of this line may be explained by the fact that the copper $K\alpha$ radiation in passing through carbon loses a part of its energy equal to that of removing the electron from the K shell either to the optical level or to infinity The frequency difference between this line and the original copper $K\alpha$ lines is 20 1 (in ν/R) whereas the value of carbon $K\alpha$ is 20 4 (in ν/R Soderman, *Zeit f Phys*, 52)

It may be mentioned here that the possibility of this type of radiation was also predicted by Kramers and Heisenberg, and it shows a certain similarity with the Raman effect in molecules

Nickel $K\alpha$ radiation produces a similar effect on passing through carbon Further, this effect has also been observed in the case of oxygen and nitrogen for copper $K\alpha$, nickel $K\alpha$, nickel $K\beta_1$, tungsten $L\alpha_1$ radiations, the measurements of which with photographs will be published in due course B B RAY

The Identity of Colloidal Particles in Soap Sols and Gels

DR M E LAING MCBAIN and Prof J W McBain found about ten years ago that several properties, for example, the conductivity, lowering of vapour pressure, concentration of sodium ion, etc, of the sols and gels of sodium oleate are identical, and from this they came to the conclusion that the colloidal particles in the two states are identical in nature and amount

It is well known that light scattering gives us an accurate idea of the delicate changes in the colloidal particles in sols and gels, and is therefore a very significant property of colloids During my investigations on the scattering of light in soap sols and gels I found that the intensity of the light scattered by gels of sodium oleate is distinctly greater than that in sols at the same temperature (NATURE, Nov 2, 1929, p 690) In a recent letter to NATURE (Jan 25, 1930, p 125) Dr M E Laing McBain and J W McBain report that they have succeeded in preparing samples of the same solution of sodium oleate, some of which were fluid sols and others typical jellies, but the light scattering of which was identical within the limits of experimental error They further suggest that the enhanced intensity of the scattered light in the gels observed by me might be due to a partial curding or crystallising out

It may be permissible to point out here that J W McBain appears to have previously observed a slightly enhanced opalescence during the formation of gels from soap solutions (cf McBain's article in J Alexander's "Colloid Chemistry", vol 1, p 140), though the other properties, such as electrical conductivity and lowering of vapour pressure, remain unaffected K KRISHNAMURTI

Intensities in Band Spectra

PROF E CONDON (*Phys Rev* 32, p 858, 1928) has shown that on the basis of the new quantum mechanics, certain nuclear transitions associated with electronic transitions are more probable than others The actual intensities of the lines emitted depend upon the integral of the electric moment and the wave functions of the initial and of the final states The evaluation of this integral can be approximately carried through for symmetrical diatomic molecules The intensities of the lines associated with vibrational electronic transitions may therefore be calculated and expressed in terms of the change in separation of the nuclei during the transition

The intensities calculated by this method agree very well with experiment especially in the case of the alkali molecules The calculated intensities for Na_2 and K_2 at the positions (1 2) and (2 1) in the band spectra double entry table for intensities are very small, thus being in good agreement with the experimental intensities given by Fredrickson and Watson (*Phys Rev*, 30, p 429, 1927) The occurence of a large number of transitions between high quantum states for iodine is also explained There are certain regular deviations from experiment in the case of hydrogen that have not as yet been explained The complete calculations will be published in the *Physical Review* ELMER HUTCHISSON

The New Planet

I SEE that, in the notice which appeared in NATURE announcing the discovery of the new planet, it was suggested that the object might represent the outermost member of the family of planets formed from a portion of the sun drawn out by the attraction of the star the approach of which caused the catastrophic formation of the planetary system, or, as it was put—the new planet might be formed from the tip of Sir James Jeans' cigar Since then the further particulars of the orbit appear to indicate that it is cometary in character, being eccentric and inclined at a considerable angle to the ecliptic These two divergencies from the characteristics of the previously known planets, coupled with its great distance, would appear to be better explained by the theory of capture At least, it may be said that the capture theory deserves consideration If capture is possible, the new planet might be regarded as the first of a new series Further, if the capture theory were actually established, by implication it would be probable that the majority of the stars have captured planets

Angler-Fishes *

By Dr C TATE REGAN, F R S

THE fins of fishes are formed of a membrane supported by rays, which are generally flexible and jointed But in one great group of fishes—the perch group—some of the fin rays, and particularly the front rays of the fin on the back, are converted into strong, sharply pointed spines, weapons of attack and defence It might be thought that these specialised structures would be end products of evolution, but that is not so, for in various offshoots of the perch tribe the spines are modified for other purposes In the flat fishes, which swim by undulating movements of the body and the long marginal fins, the spines are reconverted into articulated rays—an example of reversible evolution In the sucker-fishes, which attach themselves to sharks, turtles, and other marine animals, the spinous dorsal fin is transformed into a laminated adhesive disc placed on top of the head In the angler fishes the spinous rays of the dorsal fin have become slender and flexible, and the first is placed on the head, and forms a line and bait

The angler fish found in British seas has a large flat head, and a wide mouth furnished with sharp depressible teeth The bait is a flap of skin—sometimes white in colour—placed at the end of the line, near the mouth The angler lies on the bottom—and waves about the bait, which is perhaps better termed a lure, for it is not meant to be seized—and so entices other fishes near enough to be caught

In the seas of other parts of the world there are other anglers more or less similar to ours In some of these, as in *Lophiomus naresii* from New Guinea, the skinny flaps that look like weeds, and help to conceal the lurking fish, are much more developed than in the British species

Another group of anglers includes a number of small fishes, compressed in form, and often brightly coloured and marked with patterns of stripes or spots They are found in warm seas, many inhabiting the crevices of coral reefs One lives among the *Sargassum* weed, where its coloration of mottled brown on yellow renders it inconspicuous

The two groups of anglers so far described include fishes that live in the light, they have a coloration that harmonises with the ground on which they lie, or the rocks and weeds amongst which they rest, and their lure is a flap or a tassel at the end of the line A third group includes the anglers that live out in the ocean, and deep down in the dark, generally from about 100 fathoms to 500 fathoms below the surface, not at the bottom, but in mid-water These are uniformly coloured, generally blackish Their lure is luminous, the swelling at the end containing a glandular sac with a luminous secretion, the sac is partly enclosed in a pigmented cup, lined inside by a peculiar membrane that acts as a reflector, the light shines out through the mouth of the cup, and there is some evidence that it can be turned on or off at will Generally the mouth is large, and the teeth are strong, sharp, and depressible inwards

Another peculiarity of the oceanic anglers is the extraordinary distensibility of the stomach In the depths of the ocean meals are scarce, and the angler does not want to refuse one because it is too big There are several examples known of anglers that have swallowed fishes two or three times their own length and several times their own weight, two of these had just begun to digest the fish they had swallowed, and then took baits and were hooked and caught on lines! Others have been carried upwards by the struggles of their victims when these were first seized, and have been found at the surface of the ocean, alive but helpless I believe that these could not have escaped their fate, for their teeth are so arranged that they hold the victim that is struggling to escape, but lie down and allow a little more of it to pass inside every time its efforts relax, so that eventually it is completely engulfed, and makes a considerable alteration to the figure of its captor

In *Linophryne* the teeth are stronger than in any other angler In *L arborifer* the large luminous lure is carried by a short stout line, and below the chin is a large branched barbel, or beard The use of this appendage is unknown, it may be luminous, or the little swellings on the terminal branches may be sensory organs, perhaps giving warning of the approach of other fishes In other species of *Linophryne* the beard is different in structure, and the lure may have a series of filaments on each side of the bulb

Edriolychnus has the skin translucent, although the stomach is pigmented, the luminous organ is sessile, without any line *Gigantactis* is remarkable for the long fine line, in one species four times as long as the fish itself One is reminded of a fly fisherman The movements of the small lure may imitate the swimming movements of a small luminous animal

The line is a fin ray, and like other fin-rays is articulated to the end of a basal bone, this lies in a hollow on top of the head, but in *Gigantactis* its end projects In *Dolopichthys* the basal bone projects more distinctly, and in some other anglers the whole of it may be permanently protruded, and it may increase in length, forming a rod

Lasiognathus (Fig 1) is a complete angler, for it has not only a rod and a line, but also a triangle of hooks, like those used by a pike fisherman In this extraordinary fish the upper jaw is connected to the head by a membrane, the prey, perhaps brought to the mouth by the hooks, must be completely enclosed by a downward movement of the upper jaw, when the membrane connecting it to the head forms the sides of a pouch, the teeth are bristle like, of no use for piercing, but meeting across and closing the gap in front of the lower jaw,

* Friday evening discourse delivered at the Royal Institution on Mar 7

when the prey is inside the mouth I suspect that this fish may feed on Pteropods, which are small enough to be taken in whole, and would offer a good hold for the hooks

There is a considerable diversity among the anglers of the ocean The lure differs greatly in size and form, and may be sessile on the head, or

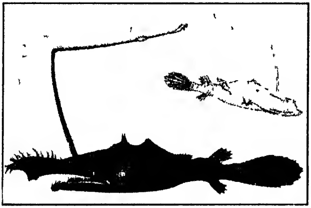

FIG 1—*Lasiognathus saccostoma* Natural size *

at the end of a short or a long line, and the line may or may not be connected with a rod, one fish even has hooks, as well as a rod and line We can get some idea of the meaning of this diversity if we reflect that human anglers specialise, there are salmon fishermen, trout fishermen, pike fisher men, and roach fishermen, each using a different sort of rod, line, and bait or lure Moreover, human anglers may use a variety of baits for the same fish, the trout fisherman, for example, may use artificial flies, spinning minnows, or worms, not to mention other methods It would also be of advantage to the anglor fishes to display a variety of lures, for if all fished with the same bait, in the same way, the inhabitants of the ocean might come to look upon it as a danger signal

The typical members of the group have a uni form coloration, a luminous lure, a large mouth, strong teeth, and a very distensible abdomen This is an example of correlated adaptations, these characters are related to the habits and con ditions of life of these fishes, and can scarcely have been evolved by accident, which is a modern theory of evolution that has some popularity

Further correlated adaptations have developed within the group In *Himantolophus* the lure is very complicated in structure, with numerous tentacles, ending in luminous tips In young examples of this genus, about 2 inches long, the lure is simpler, and the mouth smaller, than in the adult At a still earlier stage, as in all these anglers, there is no line or lure, it grows out from the head These young fishes, with relatively small mouth and feeble teeth, and with the lure absent or little developed, live nearer the surface than the adults, and feed on minute organisms But some retain these juvenile habits throughout life, they never grow to more than two inches long, and the line and lure do not develop *Lipactis* is very similar in structure to a young *Himantolophus*, but has no lure, somewhat larger eyes, and much larger nostrils, indicating that it seeks its food by smell and sight The species of *Rhynchoceratias* differ in their pincer like jaws, and some by still larger nostrils The final stage in this series—*Aceratias*—differs from *Rhynchoceratias* in having the eyes directed forwards (Fig 2), and the snout is shortened in relation to stereoscopic vision, as in man This little fish differs consider ably from the typical anglers of the ocean, but its modifications of structure are all related to the adoption of a new habit, search for food by smell and sight

Neoceratias (Fig 2) is probably related to *Gigantactis*, it has also lost the line and lure and developed the olfactory organ, but on a different plan, one nostril being at the end of a tube This curious fish has teeth outside its mouth, on the surface of the head, each is long, slender, hooked at the end, and inserted in a muscular papilla, so that it is independently moveable One may imagine the ends of two or three teeth coming together to catch something, and then passing it on to the other teeth, until it gets inside the mouth

Now comes the most remarkable thing of all All these free swimming oceanic angler fishes, black and mostly rather terrible in appearance, are females The only males of this group known are

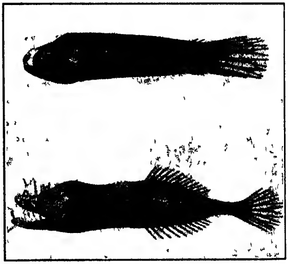

FIG 2—Above, *Aceratias macrorhinus* (× 2), below, *Neoceratias spinifer* (× 3)

dwarfs parasitic on the females A pair of fishes was taken in a trawl to the south of Iceland, they belong to a genus—*Ceratias*—distinguished by the spiny skin, and by the very long rod and short line The wife is 40 inches long, her husband is only 4 inches long, so that she is a thousand times his weight He is attached to her in the mid ventral line The male (Fig 3) has a general similarity to the female, but he has no line and bait, and no teeth He is attached to her by

* The figures are taken from two sets of picture postcards issued by the British Museum (Natural History), entitled 'Oceanic Angler fishes', and sold at 6d a set of five cards, with leaflet

means of outgrowths in front of the snout and of the lower jaw, which meet in front of the mouth and unite with a prominence on the skin of the female The union is so complete that it is difficult to say where one fish begins and the other ends, the connecting tissue is fibrous and full of blood vessels, the general direction of which is from one fish to the other, and the male is a mere appendage, nourished by the continuity of his blood system with that of the female He is quite incapable of feeding himself, for his mouth is closed in front and has no teeth, and his digestive system is reduced to a vestige But he has a heart, and gills, so that he is able to breathe, water for respiration enters through the mouth Another large female *Ceratias* was so fortunate as to possess two males, attached close together on the side of her abdomen arrangement, which has the advantage that the mouth has more room for the intake of water for respiration

These fishes are unique amongst backboned animals in having dwarfed and parasitic males, and unique among all animals in their method of parasitism, for in no other animal is there a union of the blood systems of host and parasite The nearest approach is the embryo of the placental mammals, where also parasite and host are of the same species

Now if we consider the habits and conditions of life of these fishes we can understand the evolution of the dwarfed and parasitic males The oceanic anglers are feeble swimmers, they float about waiting for their prey, and they are necessarily few in numbers as compared with the more active fishes that they attract with their luminous lure

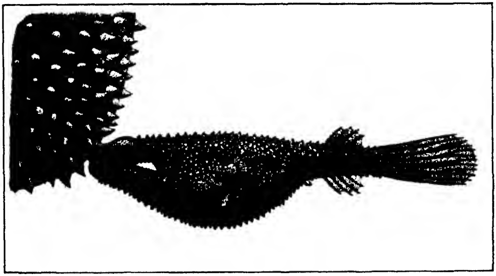

FIG 3 —*Ceratias holboelli* (male) Natural size

In these fishes the eggs are shed in the sea, and the males must be free when they are first hatched, and attach themselves if they find a female, first holding on by the mouth, and then becoming grown to her

In *Photocorynus* a female three inches long has a male only $\frac{1}{8}$ of an inch long attached to the top of her head above the right eye In *Edriolychnus* a female about 3 inches long has a fully adult male, $\frac{3}{8}$ of an inch long, attached under the spine of the præoperculum, and upside down The attachment of the male *Photocorynus* is of the same type as in *Ceratias*, by means of outgrowths in front of the snout and the lower jaw, whereas in *Edriolychnus* the main attachment is inside the mouth, which is choked up In both we must suppose that the male first nipped a piece of the skin of the female between his jaws, and that the ends of the lips fused with the papilla so formed Then if the tongue pressed against and fused with this papilla inside the mouth, the *Edriolychnus* arrangement would result, but if it were pushed forward between the branches of the lower jaw to effect a union with the female below the mouth, subsequent growth would give the other They live a solitary life, and they are in the dark Imagine such a fish, out in the middle of the Atlantic, perhaps half a mile below the surface, How could it find a mate ? But there may be thousands of males in a brood, hatched out at the same time from the eggs shed by a single female, and if these at once look for females, the chances of finding one are much greater than if they waited until later, when their numbers had diminished If they are lucky enough to find one they unite with her and develop at her expense, if not, presumably they perish

These extraordinary habits of the males have led to the degeneration of the organs they no longer need—the lure, the teeth, and the digestive system

The males of these oceanic angler-fishes are another example of correlated adaptations, of several independent changes of structure related to new habits These cannot be explained by the theory of evolution by accident—of changes of structure being due to changes in the germ-cells, that have no relation to habits and environment They fit in better with the theory that the actions and reactions of the animals themselves result in modifications of structure that become hereditary

The Geological History of the Pacific Ocean *

By Prof J W GREGORY, F R S

THE Pacific Ocean, as the greatest geographical unit on earth, with an area greater than that of all the land, presents the difficulties as well as the attraction of its size Its broad trigonal shape, nearly 10,000 miles wide from New Guinea to Peru, forms a striking contrast to the relatively narrow trough of the Atlantic, and the differences in size and shape render the recurrence of the same structural and biological units, which is so conspicuous with the opposite coasts of the Atlantic, less likely with the Pacific Its 3000 islands give little evidence as to its geological history, for most of them are composed of comparatively young volcanic ejecta or coral rock

The first striking feature of the Pacific is its apparent unity Its surrounding lines of volcanoes, the so called 'girdle of fire', its unstable marginal earthquake zone, the parallelism of its bordering mountain chains to its shores, the features which led Suess to describe its coasts as so different from those of the rest of the world as to constitute the Pacific Coast type, and the association by Prior and Harker with this type of a special suite of rocks, have all supported the conclusion that the Pacific Ocean has a geographic and geological unity which indicates its permanence throughout geological time This view, urged by Dana in 1846, has been adopted by many geologists, such as Russell Wallace, and palæontologists such as W D Matthew, and is supported by the recent verdict (1929) by Professor Schmidt of the Zoological Museum, Leningrad, that "The Pacific was formed in very ancient times and has undergone no important changes"

This belief in the permanence of the Pacific has been rejected by many authorities The existence of a Pacific continent was advocated in his presidential address to the Geological Society sixty years ago, by Huxley That the Pacific is the oldest ocean is accepted by some authorities, as von Huene, who reject its permanence In 1899, however, I argued against the Pacific Ocean having been permanent, and expressed the view that "the Pacific Ocean may have undergone great changes later than the other oceans" To that opinion I still adhere

Faith in the unity of the Pacific was strengthened by widely accepted theories of its origin The view that the Pacific Basin is the hollow left when the moon was torn away from the earth is untenable, as the moon is 37 times too big and 20 per cent too heavy The standard geological theory of the origin of the Pacific is that of Suess, who inferred from the parallelism of the surrounding mountains its unity of origin and from the marine Triassic rocks on the coasts its Triassic age

That the margins of the Pacific have been greatly altered is certain All authorities on the geology of the East Indies agree that they are fragments of a continuous land, which lasted throughout the Palæozoic and extended far into the Pacific This ancient Malaysia was continued northward as the Cathaysia of Grabau by which China extended eastward into the Ocean Australia, it is generally accepted, was once continued eastward to Fiji and New Zealand, while Asia extended, south of Japan, to the line of the Liu Kiu and Ladrone Islands

On the American side the former occupation of the eastern Pacific by land—the Schuchertland and Burckhardtland of von Ihering—is necessary to explain the stratigraphy of western America, the coarse conglomerates in Chile, and the sudden truncation of the structural grain of South America in Peru and in Ecuador near Paita

On the northern side the Pacific was once occupied by the land bridge from Mongolia to the United States, south of the Bering Sea, which was used in four different epochs by large quadrupeds To the south the replacement of sea by land is affirmed by all those who believe in the connexion of Australia and New Zealand to South America either directly or by Antarctica

A marginal reduction of the Pacific is, however, not enough, for many botanists, zoologists, and palæontologists, from very different lines of evidence, insist that the range of plants and animals, living and extinct, requires the existence of extensive lands in the Central Pacific, and probably of land lines nearly or wholly Trans Pacific, such as the Archigalenis of von Ihering

Such striking coincidences in structure as occur on the opposite sides of the Atlantic are not to be expected with the Pacific, and it may be impossible to disprove that the community of organisms in America and Asia is not due to passage across the Bering Sea but in many cases that route is improbable, as it was not in existence at the time required, or was too far north to be in a suitable zone of latitude Many zoologists claim that the chief Pacific islands have been peopled either by inhabitants who developed in the Central Pacific or reached the islands there by migration across a land connecting them with the continent to the south west that occupied Polynesia

The geological evidence is fully consistent with this conclusion It indicates not a persistent Pacific Ocean, but the occupation of its site by a succession of narrow seas separated by land and with a predominant trend west and east Thus in the Lower Cambrian the Olenellus Sea to the north was separated from the Redlichia Sea to the south west, in the Middle Cambrian one sea spread from the Himalaya to the Rocky Mountains, and an arm of it, in the Upper Cambrian, overspread eastern Australia The whole of the southern Pacific from New Zealand to South America may have been land, for the only Cambrian in South America was an arm of the Atlantic

The Ordovician in Pupiao in southern China

* Presidential address to the Geological Society of London on Feb 21

has "scarcely any trace of an American element", the fauna there is European China and western America had no direct marine connexion

In the Devonian the East Indies and the China Sea were occupied by a land that extended into the western Pacific and bounded the sea by which the European fauna reached south eastern China and Tongking In the Middle Devonian the sea with the Flabellites fauna lay along western South America and in the valleys of the Amazon and Mississippi, but it did not reach Australia, where, in the Upper Devonian, the Chemung fauna of New York invaded New South Wales the absence of this fauna from Asia and California shows the separation of the north western and south eastern Pacific seas

The Carboniferous had the same separation of the Asiatic and West American marine faunas and evidence of land is given by *Gigantopteris*, a member of the Gondwana flora, which is found in southern and eastern China and in Texas, and doubtless entered both from a Pacific land

The Trias has a wide range around parts of the Pacific, but was deposited in separated seas—an Arctic Ocean with a gulf to British Columbia the western end of a southern European sea which reached Venezuela and South California, the eastern end of the same sea extended past the Himalaya to New Zealand It is represented in New Zealand by a distinct province which was in a gulf and was not the opening to a Pacific Ocean Evidence of trans Pacific lands in the Trias is given, according to von Huene, by the affinities of the Triassic reptiles of South America to those of India

The Jurassic was the time of the main development of the Pacific continent of Haug The Liassic sea of the North Pacific was separated from the contemporary seas in Central and South America The Malm fauna of Chile ranged westward to the Himalaya, but was different from that of the North Pacific and the European fauna in the Antillean region The Pacific region in the Upper Jurassic according to Uhlig was occupied by faunas of four geographical provinces

In the Cretaceous shallow water connected California and India, while later a land separated the Senonian faunas of California and Japan from that of Chile and New Zealand The North Pacific was crossed by the giant Sauropods in their range between Mongolia and Montana, and a land route in a suitable latitude was used twice later by large quadrupeds The South Pacific was crossed in the Cretaceous by reptiles, that migrated between South America and Asia, as the route via North and Central America was not then available Lands west of America allowed the diffusion of the Dakota flora (Turonian) southward to the Argentine

In the Kainozoic Era the trans Pacific lands seem to have lasted until the Oligocene or early Miocene, since the alligator, various reptiles, amphibia, insects, crayfish, land mollusca, primitive mammals, etc, indicate migration routes across the tropical and warm temperate zones Land plants do the same, for Asa Gray showed that the floras of China and the southern humid areas of the United States have much in common *Gordonia*, one of the plants found in both areas, helps to fix the date of the migration, as it has been recently discovered by Berry in the Miocene of the Rocky Mountains

The occurrence of similar animals and plants on opposite sides of the southern oceans has been explained by their origin in a northern land or their independent evolution The northern monopoly of evolution is opposed by the theory of Ernst Schwarz of the southern origin of the mammals, and the evidence of the development of various animals, including some freshwater fish (vide Regan) and many plants in the southern land The evidence of parasitology renders the alternatives to the spread of some animals across the southern Pacific, according to Launcelot Harrison, "merely grotesque"

The life of the Pacific islands, according to many authorities, can only be explained by the existence of extensive Pacific lands on which developed a Eu Pacific fauna and flora These lands must have been connected with Polynesia and Australasia, and were probably united to the former extension of the Andes to the north west of Peru, according to Steinmann his Chimu andes extended to Hawaii and Polynesia, and were cut off from South America at the end of the Eocene

Lands survived across the Central Pacific apparently until the Lower Kainozoic, but as the higher mammals and birds characteristic of the Upper Kainozoic are distinct on opposite sides of the Pacific, the land bridges were destroyed before these animals could use them

Darwin's theory of coral islands—now established by the boring at Funafuti, gravity observations on Jaluit, the widespread presence of mid Kainozoic foraminiferal limestones, the drowned nature of the coasts of many of the islands, and the botanical evidence from the Marquesas of their subsidence for thousands of feet—implies the sinking of a belt across the Southern Pacific during the Upper Kainozoic

The evidence of the sedimentary rocks that the crust subsides to amounts up to 50,000 feet is opposed to the extreme form of isostasy, which denies the possible uplift of an ocean floor The arguments in favour of that view, based on a sub oceanic heavy stratum, as proved by the distribution of igneous rocks, gravity observations, and the speed of earthquake waves, rest on such doubtful assumptions that geologists should be guided by the direct geological evidence

The long Altaid and Alpine mountains were doubtless continued across the Atlantic and the Pacific by at least raised belts The ending of the Altaid line in the south eastern part of the main island of Japan, and of the Alpine lines in southern China and the East Indies indicate their former extension into the Pacific Its floor must have been disturbed by the forces that crumpled strips across the whole length of Eurasia into fold mountain chains, by the mutual pressure between the northern dome of the world and the protuberant tropical belt

News and Views

Congratulations and good wishes are offered to Dr George Claridge Druce, who will be eighty years of age on May 23. The story of his earlier years has been told by Dr Druce himself in the introduction to the "Flora of Buckinghamshire" (1926), the third of his series of floras descriptive of the Thames valley counties. The autobiography tells of difficulties successfully overcome by hard work and perseverance, and is an interesting record of the zeal and industry with which from early boyhood Dr Druce has, almost literally, pursued the study of our British flora, and has gained a knowledge of the rarer plants in their native habitats which is unique. This has been achieved in the intervals of an exacting business life—that of a pharmaceutical chemist. For many years Dr Druce has been honorary curator of the Fielding Herbarium at Oxford, and, in association with a former professor, Dr S. H. Vines, has published accounts of the historic collections at the University, notably the Dillenian and Morrisonian herbaria. The field botanist is indebted to him for a modern edition of the best used handbook on British plants—Hayward's "Botanist's Pocket Book"—and Dr Druce has also himself compiled a "List of British Plants."

Since 1904, Dr Druce has been the moving spirit of the Botanical Exchange Club, the annual report of which supplies records and critical notes on members of the British flora. In 1908 its circle of interest was extended by the formation of a society which should include well wishers in addition to active workers. Dr Druce's botanical interests are not limited to the British flora. He has travelled widely, his visits extending so far as Australia and South America. Our latest news of him was that he was botanising in Cyprus, an account of a former visit to which he recently described at a meeting of the Linnean Society. That Dr Druce should have received an honorary M.A. degree and later the Sc.D. of Oxford is evidence of the esteem in which his work is held and the position he has won in the University town in which he has for many years lived and worked. A further recognition was the fellowship of the Royal Society, to which he was elected in 1927.

It is now well known that certain forms of vomiting are primarily caused by depletion of the body's store of carbohydrate; in such conditions the administration of an easily assimilable sugar is an important part of the treatment. All carbohydrates are absorbed after digestion as monosaccharides and ultimately converted into glucose or glycogen; hence for quickest absorption without the need for preliminary digestion glucose is indicated. It is useful in the prevention of cyclical vomiting in children, as a source of food in starvation during illness, in the cure of insulin hypoglycæmia, and has been recommended in surgical shock, chloroform poisoning, and asthma. The vomiting of sea sickness is frequently preceded by acidosis; the administration of glucose may prevent it, or may abolish it if it has already occurred. There is evidence that certain toxic agents exert a less deleterious action on the liver when that organ contains a good store of glycogen; glucose is the simplest form of carbohydrate to administer to ensure rapid filling of this store. Pure medicinal glucose can be obtained in the form of a white powder from Messrs. The British Drug Houses, Ltd., London, N.1; for the preparation of a sterile solution suitable for subcutaneous, intravenous, or rectal injection, it is also issued in a concentrated sterilised solution in sealed tubes.

The earthquake of May 5, which was recorded at Kew Observatory at 13 hr. 58 min. 11 sec. G.M.T., was the strongest, indeed the only great destructive earthquake, ever felt in the south of Burma. The centre seems to have been near Pegu, the ancient capital of the country. Of this city of 14,000 inhabitants, the greater part is destroyed, the pagoda, the municipal offices and the main street being in ruins. After the earthquake, a fire broke out in the most congested quarter of the town and an area of about two square miles was swept by the flames. As in San Francisco, Tokyo, and Yokohama, they spread unchecked owing to the destruction of the water mains. The number of persons killed in Pegu is estimated roughly at from 600 to 1000, not an excessive number seeing that the earthquake occurred at night. At Rangoon, about 45 miles to the south-south-east of Pegu, 46 deaths are reported, while many buildings are seriously injured. The total number of shocks felt in Rangoon up to 1904 is given by Montessus de Ballore as only five, of which one in 1888 was strong enough to throw down a few chimneys, and another, 1894, to unroof or shatter some, but not many, houses. Farther to the north, in the district surrounding Amarapoora and Ava, shocks are much more frequent, while that which occurred on Mar. 23, 1839, must be reckoned as one of the world's great earthquakes. It may be of interest to add that the burned out areas of Tokyo and Yokohama in 1923 contained about 7 square miles and 3 square miles respectively, while that covered by the great fire of London in 1666 was not more than two thirds of a square mile.

In 1898 the British Association met in Bristol, and in the following year a University College Colston Society was formed, on the lines of the Colston societies already in existence commemorating the work of Edward Colston, but for the express purpose of supporting University College, Bristol. After various slight changes of title, the society still exists as the Colston Research Society, a unique association of citizens for the promotion and assistance of research in the university of their city. A brief history of the Society and record of its work has been prepared by Dr Morris W. Travers. For a number of years the Society's activities took the form of an annual appeal in the president's name, as a result of which about £500 a year was handed over to the Council of University College, Bristol. In 1908 a part of the Society's

funds was diverted to the promotion of the scheme for a University of Bristol, and with its foundation the Society used its funds to finance research in the University An experiment in the form of industrial research fellowships was inaugurated in 1922, and six industrial firms each agreed to subscribe £150 for the support of as many research fellowships for one year, the donor having the right to choose the line of research adopted The scheme proved difficult to work in the University laboratories and has not been repeated In 1927 it was announced that a fellowship had been established in connexion with cardiac research being carried on in the University, thus reverting to one of the original aims of the Society Last year the Society received a sum of £5000 from Mr R H Mardon to form a trust fund for the endowment of research, and Mr Mardon also made himself responsible for the additional charges for incorporation of the Society which his gift necessitated The citizens of Bristol can look back on their steady support of research and higher education with pride and satisfaction, and it may be hoped that their Colston Research Society will be copied in other university cities of Great Britain

THE thirty sixth James Forrest Lecture of the Institution of Civil Engineers was delivered on May 5 by Prof R V Southwell, who took as the subject of his address—"Aeronautical Progress, 1914 to 1930" This was the first opportunity the Institution has had for viewing in perspective the extraordinary advances which have been made in aerial locomotion since the period prior to the War, and was all the more apt since the last lecture dealing with the subject was given by Dr Lanchester in May 1914, to an audience ignorant of what the future held in store for it Prof Southwell stressed the remarkable fact that the kernel of all we yet know of fundamental aerodynamic theory was to be read in the 1914 lecture by such as could understand Dr Lanchester had been at great pains to give estimates of the gains that might be expected to accrue from improved design in speed, range, etc, and while his forecast of the rate of future progress has naturally been surpassed by actual achievement under the accelerating influence of the War, Prof Southwell insisted that he could find no direction in which he underrated what was practicable, with the possible exception of the internal combustion engine This view was supported by a brief summary of the progress made during the last sixteen years Turning to some theoretical aspects of the subject, Prof Southwell praised the influence which the Advisory Committee for Aeronautics has exerted both on the industry and in the direction of scientific research under the guiding wisdom of Sir Richard Glazebrook It seems remarkable that this new wing should have so organised itself as to provide a continuous channel between pure scientific research and its direct application to industry when so many fields of industrial development of much older date have not yet succeeded in establishing anything like this continuity The remaining part of Prof Southwell's lecture was taken up with a critical scrutiny of the more modern developments on the theoretical side, stressing in conclusion that there are many lessons to be learned by older branches of engineering from the newer progress, by those who are prepared to translate the new developments into the language of the non aeronautical engineer

DR FAY COOPER COLES, retiring vice president and chairman of Section H of the American Association for the Advancement of Science, in his address at the meeting held in December last at Des Moines, paid a warm tribute to the educational system for natives established by the British in the former German territory of Tanganyika The subject of the address, which is printed in *Science* for Mar 7, was the relation of anthropology to Indian and immigrant affairs—a subject upon which Dr Coles is peculiarly competent to speak in virtue of his residence of four years among the natives of the Philippines while collecting and recording information on behalf of his museum The reference to the work of the British was quoted to afford a contrast with the methods adopted by the American administration in dealing with Indian affairs It was pointed out that the United States has at its disposal a mine of information and a great research organisation, yet instead of having the most advanced native policy in the world, Indian affairs are under the control of a Board of Commissioners, few of whom have been recognised as authorities on Indian life and customs, while the Indian Office has often been entrusted to men ignorant of and indifferent to Indian custom He referred to ill advised attempts to suppress Indian rites instead of moulding them gradually so as to bring about the adaptation of the Indians to modern civilisation as is being done in the case of the natives under British rule Dr Coles also referred to the practical value of anthropology in relation to immigration Now that immigrants are drawn predominantly from the south and east of Europe rather than the north west, anthropological studies would afford that knowledge of the cultural background of the incoming peoples which is essential if their absorption into the State is to be facilitated and they are to be prevented from consolidating into compact communities perpetuating the Old World feuds and customs which, in present conditions, delay their participation in American life

AT a recent meeting of the Geological Society of America, Col Lawrence Martin, chief of the Division of Maps at the Library of Congress, announced that two consultants, in geology and geography respectively, have been added to the Library services The specialists at the Library, termed consultants, as distinguished from the incumbents of the several 'chairs', have lately been increased for a period by a grant from the General Education Board which, by providing small honoraria, has enabled six such specialists to be added to the service The essential difference between the incumbents of 'chairs' and the research consultants is that the former are engaged in the administration of divisions of the Library of Congress, as well as in the interpretation of the materials under their custody, while the consultants serve in a purely individual and advisory capacity, rendering counsel in response to suggestions and inquiries, by visit or

by correspondence The geologist and the geographer who, for part of the present year, are to be associated with this advisory service as consultants are Prof A C Lane of Tufts College, Mass, who will come within the group provided by the grant of the General Education Board, and Prof A P Brigham of Colgate University, Hamilton, N Y, whose service, however, will be purely honorary This consultant service is purely experimental, its continuance depends on the use made of it

IN the British Broadcasting Company's regional scheme, five twin radio transmitting stations are to be constructed, each of which will be capable of radiating simultaneously two programmes on different wave lengths The five centres will be located in Scotland, North England (industrial), London and south east England, the Midlands, and the south west of England The Midlands station at Daventry and the London station at Brookmans Park, are already in operation In a paper read to the Institution of Electrical Engineers on May 7, P P Eckersley and N Ashbridge gave some of the considerations which led to the choice of these sites, and gave also a detailed description of the Brookmans Park broadcasting station In choosing this site, account had to be taken of the fact that for several years listeners in the neighbourhood of London had been accustomed to listen from a two kilowatt transmitter in Oxford Street To erect a fifty kilowatt transmitter on the same site would produce an intolerable 'wipe out' If they had chosen a site eastwards on the Thames estuary much of the service area would have been over the North Sea In a southerly direction the erection of masts on the top of the North Downs, which would have been a good site, was prevented by civil aviation regulations The site finally chosen lies on the east side of the Great North Road, on the London side of Hatfield It is in the centre of a flat field 34 acres in extent Diesel engines are used to produce the 500 kilowatts required, and very special precautions have been taken to prevent a break down as continuity of supply is essential If any essential valve breaks down, it can be replaced in about fifteen seconds

THE raw materials required by the Osram Works at Hammersmith come from all parts of the world In an article in the General Electric Company's bulletin for February, an interesting account is given of the materials used for Osram lamps The metal tungsten from which the filaments are made is obtained from scheelite, a whitish yellow stone of rough texture which is found in north eastern Australia In its rough state it is shipped round the Cape of Good Hope to London, where in the Osram works it undergoes the processes of crushing, grinding, washing, acid treatment, and heating The final result is the fine and very heavy black powder, which is pure tungsten It is then pressed, hammered, and drawn into the familiar lamp filament Shellac, which is one of the essential ingredients forming the cement which attaches the lamp cap to the glass bulb, comes from India The insects which form it breed in countless numbers in the valley of the Ganges They absorb the flowing sap from young shoots of young trees and then exude a resinous secretion over their whole bodies The twigs bearing the insects are gathered and from them commercial shellac is produced The nickel and copper used in the special leading in wires which conduct the current in and out the lamp bulb come from Canada The tin for solder comes from Malay The sand, soda, and lime used for making the glass of the bulbs is got in England, and so also is the minute amount of iron which helps to make the alloy used for the leading in wires The diamonds used for the dies through which the filaments are drawn come from South Africa The sources of all the raw materials required for the manufacture of the electric lamps lie in British territory

IN our columns of Oct 19, 1929, p 629, mention was made of the fact that the Imperial Agricultural Research Conference had recommended that the Low Temperature Research Station at Cambridge should issue from time to time lists of elaborated titles of useful publications in the field of food investigation and a brief review of the first of these lists was given We have now received the second part of the first volume of this index (Department of Scientific and Industrial Research Index to the Literature of Food Investigation Vol 1, No 2, September 1929 Compiled by Agnes Elisabeth Glennie Pp iv + 154 London H M Stationery Office, 1930 2*s* net) The arrangement of the sections and subsections is similar to that in the previous part It is proposed to include in the first number of each annual volume a brief review of the previous year's progress in the subject of food investigation This bibliography should be extremely useful to all workers on the production and preservation of different articles of food, by putting them in touch with work being carried out in other countries than their own

THE restoration of Avice's cottages to form the Portland Island Museum has been completed, and we learn from a communication from Mr H J Sansom and Dr Marie C Stopes, honorary secretary and honorary curator, respectively, of the Museum, on behalf of the Museum Committee, that all the expenses of restoration have been fully paid up The Museum is now ready to receive antiquities and specimens associated with Portland Particularly welcome would be old prints and maps of Portland, books containing references to Portland, either scientific, historical, or purely literary, well authenticated furniture, coins, etc, pre historic remains and fossils found in Portland, preserved specimens of the existing flora and fauna, photographs of famous buildings built of Portland stone, legends, folk songs, song games, old customs, etc, written down by Portland folk Glass-fronted display cases are wanted and also money for an equipment fund As the building is now ready, it is hoped to hold the opening ceremony during the last week in July of this year Specimens and exhibits should if possible be accompanied by a letter giving the fullest available information about each, and should be addressed to the Portland Island

Museum, c/o Mr H J Sansom, Pennsylvania Castle, Portland

There has been in the past some little confusion in regard to methods of specifying access of daylight into buildings The method adopted is based on the use of either of two factors, the 'daylight factor', which is the ratio of the internal illumination to the illumination of a horizontal surface exposed to a hemisphere of sky, and the 'sill ratio', which is the ratio of the internal illumination to the illumination of a horizontal surface exposed to half a hemisphere of sky (as is the case for a surface resting on the window sill) The second of these factors is necessarily double the first In the series of papers, technical papers on illumination research, issued by the Department of Scientific and Industrial Research, it was intended to use the sill ratio In 1928, however, international agreement to make use of the daylight factor was attained, and accordingly this method is to be used in all future publications of the Illumination Research Committee The only existing publications of the Committee in which values of the sill ratio are employed are those on "The Natural Lighting of Picture Galleries" (No 6) and "The Penetration of Daylight and Sunlight into Buildings" (No 7) In both cases the values should be halved so as to express them in terms of the 'daylight factor'

Two discoveries of special interest in the anthropological field are recorded in the recently published Report of the National Museum of Canada for 1928 Dr J Wintemberg has found a camping site of the extinct Beothuk Indians on the north side of Belle Isle, and a camping ground of the Iroquois near Kegashka Both discoveries add to the territory known to have been ranged by these tribes The interesting tribes of the Beothuk, who formerly lived in Newfoundland but have long been extinct, are thus shown once to have occupied the east corner of Labrador, a fact not hitherto known, while the Iroquois discovery is several hundred miles east of the known range of their forays Although these are the most interesting of the discoveries made by the museum staff in the field during the year, excellent work was done by other expeditions Dr Harlan I Smith was collecting archæological and ethnological specimens in British Columbia and taking motion pictures of the Salish, Blackfoot, and Cootenay Indians, Mr C M Barbeau was studying French Canadian arts and crafts in Quebec, Dr J C Boileau Grant conducted anthropological investigations on Cree and Chippewayan Indians on Lake Athabasca, and Mr C B Osgood travelled on the Mackenzie River, where he wintered with a band of Hare Indians on Great Bear Lake

The late Mr J D Logan presented to the trustees of the National Botanic Gardens at Kirstenbosch, South Africa, forty acres of land near Matjesfontein in the Western Karroo, where the interesting succulents in which the Karroo is so amazingly rich may be cultivated under natural conditions Prof R H Compton, director of the Kirstenbosch Gardens, has a brief article upon this interesting garden experiment in the *Kew Bulletin*, No 2, for 1930 This Whitehill Garden was seen by many of the visiting botanists during the recent meeting of the British Association and much interest was aroused The district is extraordinarily rich in species, Prof Compton has collected approximately 400 species of flowering plants and ferns in the garden itself, or on Karroo rocks in the immediate vicinity With a winter rainfall which probably averages only 5 inches per annum, these plants include a number of the striking succulents for which this region of the Karroo is famous The area was enclosed by a goat proof fence when first selected in 1920, but it was only in 1925 that it was possible to appoint a curator The gardens are financed entirely from private subscriptions and no public body makes any contribution to its support As Prof Compton says, therefore "progress is slow and the future precarious", but the plants in this garden are so extraordinarily interesting that it is earnestly to be hoped that this uniquely interesting experiment in botanical gardening will prove a permanent success

At the anniversary meeting of the Royal Society of South Africa, held on Mar 19, the following officers were elected *President* Dr W A Jolly, *Honorary Treasurer*, Dr L Crawford, *Honorary General Secretary*, Dr B F J Schonland

The Secretary of State for the Colonies has made the following appointments in the Colonial Agricultural Services Mr A E Haarer, district agricultural officer, Tanganyika Territory, to be agricultural lecturer, Tanganyika Territory Mr A B Harper, to be produce inspector, Nigeria

It is announced in *Science* that the Rumford Premium of the American Academy of Arts and Sciences was presented on April 9 to Dr John S Plaskett, director of the Dominion Astrophysical Observatory, Victoria, B C, in recognition of his researches on stellar spectroscopy

A discussion on magnetism is to be held by the Physical Society on Friday, May 23, at the Imperial College of Science, Imperial Institute Road, South Kensington, S W 7 The meeting will consist of two sessions, 3 4 30 P M and 5 15 7 P M, and the discussion will be opened by Sir Alfred Ewing, with a contribution on "Ferro Magnetism and Hysteresis" Other contributors to the discussion include Dr E C Stoner, Prof H S Allen Prof C G Darwin, Mr W Sucksmith, Mr F C Powell, Prof W Peddie, Prof P Weiss and Dr R Ferrer Prof W Gerlach, Dr P Kapitza, Dr W L Webster, and Dr L F Bates Admission is free without ticket

Mr R A Watson Watt, writing from Datchet, points out that the note in Nature of May 10, p 717, on halo phenomena of May 1, did not refer to the really rare occurrence of the halo of 46° He adds "About 17 h G M T on May 1 I saw from Datchet the 22° halo, two exceptionally brilliant mock suns, with short arcs of the mock sun ring, and the upper two thirds of the 46° halo, which was more brilliant and more definitely coloured than on any other of the three or four occasions on which I have seen it"

WE much regret to announce the death on May 13, at sixty eight years of age, of Dr Fridtjof Nansen, the distinguished Arctic explorer and naturalist

AT a general meeting of the members of the Royal Institution, held on May 5, it was announced that the Managers had received and accepted from the Trustees of the Rockefeller Foundation an offer of a donation of £20,000 for endowment of research in the Davy Faraday Laboratory, on condition that the sum of £50,000 for the same purpose should be secured by the Royal Institution from other sources before June 30, 1933, with an additional payment of £1000 per annum up to a total of £3000 for maintenance of research in the Laboratory until such time as the capital payment should be made The thanks of the members were returned to the Trustees of the Rockefeller Foundation for their generous proposal

THE Second International Congress for Sex Research will be held in London in the house of the British Medical Association, Tavistock Square, on Aug 3–9 Among the subjects to be discussed at the general meetings are puberty and maturity, physiology of the sex glands, hormone therapy Membership is restricted to professional biologists engaged in research on, or teaching in accredited institutions, anatomy, anthropology, botany, medicine, physiology, psychology, sociology, veterinary science, or zoology and to members of the medical profession Those wishing to take part in the Congress should apply to the Congress Secretary, Department of Animal Genetics, King's Buildings, The University, Edinburgh

THE Council of the Royal Society of Edinburgh has made the following awards Keith Prize for the period 1927–29, to Dr Christina C Miller, for her papers on the slow oxidation of phosphorus trioxide, published in the *Proceedings* within the period of the award, and in consideration of subsequent developments on slow oxidation of phosphorus, published elsewhere, Neill Prize for the period 1927–29, to Prof E B Bailey, in recognition of his valuable contributions to the geology of Scotland, two of which have recently appeared in the *Transactions* of the Society under the titles of (1) "Perthshire Tectonics Loch Tummel, Blair Atholl, and Glen Shee", and (2) "Schist Geology Braemar, Glen Cluny, and Glen Shee", James Scott Prize for the period 1927–30, to Prof Niels Bohr, who will deliver an address, in terms of the award, on May 26 next

A CHANGE has recently been made in the administration of the one time Laura Spelman Memorial Fellowships A Social Science Research Training Committee, under the chairmanship of Sir Josiah Stamp, has been in existence for two years, awarding scholarships intended to encourage quantitative and exact treatment of social and economic problems This Committee has now been merged for purposes of advice in the field of economics with the Fellowship Advisory Committee of the Rockefeller Foundation for the Social Services in Great Britain and Ireland Applications for fellowships should come, in all cases, not from candidates themselves but from a competent academic or other authority familiar with the candidate's qualifications All correspondence should be addressed to the secretary of the Committee, Mr N F Hall, University College, Gower Street, London, W C 1

WHEN the Society of Glass Technology, which has its headquarters in the Department of Glass Technology of the University of Sheffield, visited Aachen in May 1928 to hold a joint meeting with the Deutsche Glastechnische Gesellschaft, an invitation was given to the German society to pay a return visit to England The invitation has been accepted and the return visit will take place on May 26–June 3 next The party is expected to number about sixty Social functions and visits to works and laboratories have been arranged, starting at Sheffield, and including Chesterfield, Castleford, Knottingley, St Helens, Stourbridge, and London June 2 will be devoted to joint meetings of technical committees of the two societies On June 3 joint general meetings will be held at the Institution of Mechanical Engineers, London, at which all interested will be welcome

THE retirement of Prof H F Newall from the chair of astrophysics at Cambridge, which he occupied from its creation in 1909 until last year, provided an opportunity for recognising in a suitable way his great services to astrophysics, and it was agreed by a large body of subscribers that a portrait of Prof Newall be presented to the University to commemorate the founder of this new and active department of astronomical research at Cambridge On Saturday last, May 10, in the Master's Lodge of Trinity College, the portrait, painted by Mr Fiddes Watt, was presented by Sir J J Thomson to the University and accepted by the Vice Chancellor (the Master of Magdalene College) Sir Frank Dyson, the Master of Trinity College, the Vice Chancellor, and Sir Joseph Larmor spoke warmly of Prof Newall's work, and Prof Newall acknowledged the kindness of the subscribers both in England and abroad The portrait is to be hung in the director's room of the Solar Physics Observatory

A VERY complete summary and survey of the hospital service in the United States is given in the *Journal of the American Medical Association* for Mar 29 (vol 94, No 13, pp 921 991) The total capacity of all hospitals and sanatoriums is given as 907,133 beds and 47,939 bassinets, and it is suggested that there is an over supply of general hospitals Data are given of the staffing, laboratories, X ray departments, number of beds, and average patients per bed, and also of approved clinical laboratory service

A VOLUME of 'collected' papers, 48 in number, by members of the staff of the London Hospital and Medical School, has been issued under the title "Researches published from the Wards and Laboratories of the London Hospital during 1929" (London H K Lewis and Co, Ltd, 7s 6d net), all of which have appeared in current journals and transactions A wide range of subjects is dealt with—clinical medicine and surgery, bio chemistry and physics, physiology, pathology and bacteriology, and zoology Some of the papers are of much interest and importance, particularly one by Dr Donald Hunter recording

a case of over function of the parathyroid gland caused by a parathyroid tumour, with rapid restoration to health on its removal The volume is issued by a 'selection committee', of which Mr Hugh Cairns is honorary secretary

MESSRS Dulau and Co, Ltd, have just issued a catalogue (No 176) of upwards of 700 second hand works on botany and horticulture Copies of the catalogue can be obtained free upon application

APPLICATIONS are invited for the following appointments, on or before the dates mentioned --A principal of the Government Technical Continuation and Commercial School, Kingston, Jamaica - The Secretary, Board of Education, Whitehall, S W 1, or, for Scottish candidates, The Secretary, Scottish Education Department, Whitehall, S W 1 (May 24) An analytical chemist under the Marine Biological Association of the United Kingdom—The Director, Marine Biological Laboratory, Plymouth (May 27) A technical officer in the Admiralty Technical Pool, with experience in the design of telephones, bells, buzzers, and similar electrical instruments used in low power signalling systems—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (May 27) An assistant lecturer in political science at the London School of Economics and Political Science--The Secretary, London School of Economics, Houghton Street, Aldwych, W C 2 (May 29) An assistant lecturer in biology at University College, Nottingham —The Registrar, University College, Nottingham (May 29) A lecturer in charge, with training in engineering and workshop practice, for branch of the Witwatersrand Technical College, near Johannesburg —Chalmers and Guthrie (Merchants), Ltd, 9 Idol Lane, E C 3 (May 31) A sanitary inspector under the Sudan Medical Service —The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S W 1 A principal of the proposed Department of Business Administration at the London School of Economics—F W Lawe, 44 Hans Crescent, S W 1 A lecturer on hygiene and physical training at the Training College, Truro—The Principal, Training College, Truro A chief lecturer in the electrical engineering section of the engineering department of the Halifax Municipal Technical College--The Principal, Municipal Technical College, Halifax A full time lecturer in mining and engineering subjects at the County Technical College, Mansfield —The Principal, County Technical College, Mansfield An assistant chemist at the South Eastern Agricultural College, mainly for arsenic estimation by the electrolytic method—The Secretary, South Eastern Agricultural College, Wye, Kent A zoologist and an algologist at the Port Erin Marine Biological Station—The Registrar, The University Liverpool

Our Astronomical Column

Conjunction of the Planets Venus and Jupiter— An interesting spectacle for the naked eye will be provided by the conjunction of the planets Venus and Jupiter on May 17 The nearest approach of the two bodies will occur at 7 P M when their distance apart will be only 1¼° This will, however, be nearly two hours before sunset The two planets will set at about 11 o'clock (Summer Time) and should offer an interesting configuration during about an hour and a half preceding that time The higher object of the pair will be Venus, which will be a little above and to the left of Jupiter This will provide an excellent occasion on which to estimate the difference of colour and magnitude of the two orbs

Comet 1927*d*—M Ebell gives the following elements of this comet in *B Z* No 21

T 1930 June 12 7904 U T

$$\left.\begin{array}{ll}\omega & 187°\ 20\ 13\\ \Omega & 81\ 27\ 11\\ i & 20\ 24\ 44\end{array}\right\}1930\ 0$$

$\log q$ 0 01283

Ephemeris for 0^h

	R A	N Decl
May 16	16^h 59^m 43^s	37° 18′
20	17 31 6	36 27
24	18 15 37	33 56
28	19 17 52	27 54

The comet is approaching both sun and earth, so is likely to become brighter It is only 8¼ million miles from the earth on June 3

The Lowell Planet—Prof Stroobant has found an image on the plates taken at Uccle Observatory in 1927 which very probably belongs to the Lowell planet He is fairly certain that it is a heavenly body, not a flaw on the plate, and it fall accurately on the trajectory of the planet

The position is as follows for the equinox of 1927 0

1927 Jan 27^d 21^h 27^m 41^s U T, R A 7^h 1^m 59 7^s, N Decl 21° 17′ 59 5″, magnitude, 15 to 15 5

On comparing this position with those computed from the two parabolas deduced by Prof Banachiewicz and Dr C H Smiley, it is found to lie 0 7 of the way from the receding parabola to the approaching one, the separate ratios being 0 695 from the R A 0 714 from the Decl, the former has three times the weight of the latter Hence, if the identification is correct, the body is approaching the sun, and the eccentricity may be estimated as about 0 4 The observations in 1930 favoured *recession* rather than *approach*, but the observed arc was not long enough to settle the question

'Wolf's Numbers' for 1929 -No 122 of *Astronomische Mitteilungen* contains the counts of sunspots, made during the year 1929 by 55 observers at various stations, from which the Wolf, or relative sunspot, numbers are deduced Tables are given for (1) daily values for the sun's whole disc, (2) daily values for a central zone the diameter of which equals half that of the disc, (3) monthly values for the whole disc The 'number' deduced for the year 1929 is 65 0, the corresponding values for the years 1923–28 inclusive are—5 8, 16 7, 44 3, 63 9, 69 0, 77 8 Table 3 shows that the least active month of 1929 was September (34 4), and the most active, December (108 0) On no day of the year was the sun free from spots Advance data, corresponding to those given in Tables 1 and 2 of the above publication, are included in the quarterly circulars issued from Zurich by Prof Brunner under the auspices of the International Astronomical Union

Research Items.

Chumash Prehistory.—In 1927 and 1928, Mr. Ronald L. Olson spent some weeks excavating in the neighbourhood of Santa Barbara, California, and on Santa Cruz Island. The more important finds are reviewed and comparison between the sites of the two areas made in vol. 28, No. 1, of the *University of California Publications in American Archæology and Ethnology*. In both cases difficulty was experienced in finding burials that had not previously been rifled by relic hunters. The sites on the area facing the ocean front are of the familiar shell mound and kitchen midden type, varying in size from an insignificant scattering of a few thousand fragments up to deposits twenty feet thick. On the islands the sites are larger and more abundant. It is probable that they were occupied only seasonally and not all the year round. In all the mounds there is a progressive diminution in number of objects as the bottom of the mound material is approached, especially noticeable in the bottom two feet. This is due mainly to a decrease in shell and bone objects. Differences in pattern and style in the objects are scarcely noticeable. Mortars, pestles, metatés and mullers, flint work, fish hooks, and barbs and ornaments, if present at the various levels, show uniformity throughout. One mainland site, however, showed that there was a change in the prevailing method of grinding when the lower strata were laid down; metaté and muller were used almost exclusively, but later gave way to mortar and pestle. Post-European objects were found on these sites. It is probable that shell heaps yielding metatés and mullers are the oldest. The stratigraphical evidence points to (1) An early mainland period; (2) An intermediate mainland period; (3) A late mainland period. On the islands an early island period equates with the last phase of the early mainland and the beginning of the intermediate. A late island period occurs in which European objects are found. The sites yielded no evidence of oceanic contact, though canoes and circular shell fish hooks were found.

Human 'Missing Links'.—In the Smithsonian Report for 1928, Gerrit S. Muller deals with this topic as illustrated by *Pithecanthropus erectus* and *Eoanthropus dawsoni*. The author commences by giving a general statement of the question at the present time, and points out that there is a considerable divergence of opinion on the subject. The two types are essentially different in that the *Pithecanthropus* remains consisted of an ape-like skullcap, ape-like teeth, and a man-like femur, while *Eoanthropus* furnished a man-like brain case, man-like teeth, but an ape-like lower jaw. He then discusses whether an agreement on the position of the two forms is possible. Instead of giving an answer, he takes each type in detail and gives a full summary of all the published opinions on the various different points in connexion with them. The paper is illustrated by photographs of all the actual remains or casts thereof without any attempts at reconstructions. Perhaps the most valuable part of the paper is a complete bibliography of all the memoirs or articles in which the two forms have been discussed.

Special Skin Affections Due to Common Plants.—It is probably common knowledge that some persons are especially sensitive to a substance contained in the little glandular hairs upon the Japanese primula, and through contact with this plant may develop a painful inflammation of the skin, which may last for months, or even years, unless the cause is rightly diagnosed and appropriate treatment employed. An article by K. Touton, of Wiesbaden, in *Die Naturwissenschaften* for Feb. 7, 1930, enumerates an astonishing number of less well-known cases of skin affections which have been traced in a similar way to the special sensitivity of the victims to the particular plants. In some cases, of course, prolonged exposure to the causal conditions may be necessary, as in the yellow colour of the skin, due to deposition of carotin, produced by continued indulgence in oranges, or the skin affection in the left hand sometimes occurring in the orangeries amongst the orange pickers. The author concludes his account of a long list of skin troubles caused by various familiar cultivated plants with the suggestion that on another occasion he may direct attention to some forty other plants, with which man comes frequently into contact, which have also been proved to exert a stimulating effect upon the human skin in some cases.

The Basis of Colour Changes in Animals.—Prof. G. H. Parker has published a useful summary of the state of knowledge concerning chromatophores (*Biol. Rev.* and *Biol. Proc. Cambridge Phil. Soc.*, vol. 5, p. 59, 1930). Active colour changes in animals are conspicuously developed only in the cephalopods, the crustaceans, and the cold-blooded vertebrates, and in each group a distinctive type of chromatophore has arisen. All these animals have well-developed eyes, and it would seem that in all these groups the eye plays a most important part in initiating the colour changes. But it is no direct reaction, for even in highly organised instances the chromatophoral responses partake of the nature of a reflex rather than of a higher nervous response, and must be regarded as indicating a reactive capacity of relatively low order. The colour responses may be excited through the direct stimulation of chromatophores by external influences, through hormones, or through nervous impulses, but the first is the least common of these modes. Although the biological significance of the chromatophore systems in animals is by no means obvious, it seems certain that in many creatures they are utilised in developing protective or aggressive coloration, while in others they play an important part in behaviour during the breeding season, in heat regulation, and in other such subsidiary functions. These views, however, await experimental confirmation.

Rattlesnakes of the Western United States.—Scale counts and comparative measurements made on well over a thousand specimens of rattlesnakes from most of the western States and northern Mexico, have led Laurence M. Klauber to revise the relationships of species and subspecies in that region (*Trans. S. Diego Soc. Nat. Hist.*, vol. 6, No. 3, p. 95, 1930). The general tendency of his investigation is to show that these areas are peopled by a series, seven in number, of subspecies of *Crotalus confluentus*, and that California and Nevada forms hitherto ranked with the tiger rattlesnake (*C. tigris*), also belong to *confluentus* as connecting links. One result of the new ranging of subspecies is that in certain cases two subspecies of the same species have overlapping areas of distribution without showing any intergrading forms. By some, such a condition is supposed to be impossible, but the author does not see why it should not occur, and thinks that overlapping of conspecific forms is most likely to occur in regions, such as that west of the Rockies, relatively contorted both topographically and climatically.

Philippine Camphor.—In the *Philippine Journal of Science*, Vol. 41, No. 2, February 1930, Augustus P. West and H. Taguibao give the result of the examina-

tion of young trees of the laurel camphor, *Cinnamomum camphora*, which have been planted by the Philippine Bureau of Forestry since 1910, with seeds obtained from Japan In Formosa and Japan the bulk of the crystalline camphor is obtained by a crude process of distillation from the wet wood of old trees, the leaves containing mainly camphor oil In these young trees in the Philippines, very little camphor was found in the wood, but the leaves yielded 2 7 per cent on the dry weight The authors point out that some of the trees examined contained practically no crystalline camphor in the leaves, but these trees yielded a lævo rotatory camphor oil distinct from the camphor oil of commerce, which is dextro rotatory and occurs along with the crystalline camphor The authors discuss the possibility of obtaining supplies of camphor from the Philippine trees able to compete with the synthetic product made from the pine tree turpentine, which contains usually about 70 per cent pinene They point out also that the Philippine pines (*Pinus insularis*) may be a valuable source of this synthetic competitor, as they appear to yield a turpentine rich in pinene

Hybridisation in the British Flora —Messrs E M Marsden Jones and W B Turrill, of the staff of the Herbarium, Kew, have a very clear note on this subject in the *Gardeners' Chronicle*, Mar 15 Their general conclusion, based on taxonomic observation and breeding experiments with common plants of the British flora, is that "hybridization is one, but only one, of the factors of organic evolution" They describe the origin of a tetraploid hybrid, a 'culti species' which breeds true, by crossing under controlled conditions *Saxifraga rosacea* with *S granulata* The same hybrid has been recorded as occurring naturally on the Continent They compare the behaviour of the two genera *Silene* and *Centaurea* In *Silene* natural hybridisation, effective in maintaining new forms, seems to occur only *within* the species, amongst the various forms included in this taxonomic group The two species *S maritima* and *S vulgaris* will cross readily and do hybridise in Nature, but the resultant hybrid forms seem to have no permanence in Nature and are only found in limited regions where the habitats of the two species overlap In *Centaurea*, on the other hand, in the '*nigra*' group, hybridisation between certain taxonomic species is extremely frequent and seems to be responsible for the existence of a large number of these taxonomic units, which are either hybrids, segregates, or the results of back crosses to one parent The authors conclude definitely that the chief cause of polymorphism among the British knapweeds is hybridisation and that plants considered as distinct species by a specialist on the genus are hybrids The distinction between this inter specific hybridisation in *Centaurea* and the intra specific hybridisation in *Silene* obviously cannot be over stressed, as it depends, in part, upon the relative extent to which specific analysis has been applied by the taxonomist within a group of allied forms in two different genera

A New Ordovician Gastropod —With great difficulty sufficient material has been obtained by Mr E Kirk to justify the description of a new Ordovician gastropod from the Great Basin region of Nevada (*Proc U S Nat Mus*, vol 76, art 22) *Mitrospira longwelli*, n gen et sp, is highly characteristic of a fairly narrow zone in the upper portion of the Pogonip beds Despite its sinistral aspect, the author gives reasons for considering it to be an extreme hyperstrophic example of a dextral shell allied to *Maclurites*, for one species of that genus in the Pogonip at times shows a slight eversion of the whorls giving a slightly convex outline to the lower surface So far, no antecedent form to *Mitrospira* has been met with and the only other known gastropod with which it may be compared is *Palliseria*, Wilson An interesting feature shown by vertical sections is that the apical whorls were progressively filled with secondary deposits of lime during the life of the animal, very similar to that which occurs in certain species of *Natica*

The Tango (Japan) Earthquake of Mar 7, 1927 — Although the Tango earthquake of 1927 has been more closely studied than perhaps any other earthquake, Prof S Nakamura has added some interesting facts in a paper recently translated into English (*Science Reps of the Tohoku Imp Univ*, vol 18, pp 419 472, 1929) The two faults along which displacements occurred have been described in these pages (NATURE, vol 122, p 36) The author visited the Japan Sea coast ten days after the earthquake The previous sea level was well marked by lines of living shell fish and sea weeds, showing that the coast had been elevated from a point 1¼ miles east of the seaward end of the Gomura fault to a point about 7 miles to the west of it The maximum uplift, of 2 feet, occurred about the middle of this distance Some idea of the intensity of the shock is given by the maximum acceleration of 4500 mm per sec per sec at Mineyama, a town almost completely destroyed by the earthquake Many observations on the rotation of objects were made, and it was found that the anti clockwise rotation prevailed near the Yamada fault and the clockwise rotation near the Gomura fault The shear along the former fault was clockwise and along the latter anti clockwise

Climatic Changes in Central Asia The theory of the progressive desiccation of western Central Asia has been supported by Sir Aurel Stein, Prof E Huntington and others who have examined the evidence on the spot It has, however, been rejected by other travellers, including Dr Sven Hedin and Prof J W Gregory In a paper in the *Geographical Journal* for April, Lieut Col R C F Schomberg discusses the climatic conditions in the Tarim basin, and comes to the conclusion that changes in aridity and distribution of population have been caused not by climatic changes but by natural deviations in the course of streams The soft friable nature of the soil lets stream courses change easily Any slight increase in the volume of a stream may throw it off its course and mean the abandonment to aridity of large areas Again, a river cutting downwards tends to be impeded and so diverted by its banks caving in The abandonment of cultivation may be caused not only by a river changing its course, but also by the level of the water falling, as the bed is cut downwards, and becoming too low to be available for convenient irrigation Col Schomberg discusses also the value of evidence obtained by the existence of dead tamarisk and other trees which have often been cited as evidence of weather conditions in the past He finds this evidence somewhat perplexing, since at times a luxuriant growth of new tamarisk occurs side by side with many dead bushes

Absorption of Sound —When standing waves are set up in a pipe having a source of sound at one end, and a reflecting diaphragm at the other, the relative amplitudes of the changes of pressure at nodes and antinodes will be determined by the extent to which the energy reaching the diaphragm is thrown back into the pipe Some measurements of the absorption coefficients of a number of materials by this method are described by A H Davis and E J Evans in the

April number of the *Proceedings of the Royal Society* A loud speaker was used as the source of sound, and the standing waves set up in an iron tube 30 cm in diameter and 250 cm long, the end of which was closed by a steel disc supporting the test specimen in a wooden ring The change of pressure through the tube was found by means of a second smaller tube, connected to an external electrical registering system The materials investigated were mostly those which are fairly good absorbers of sound, and records were obtained of the effects of the thickness of material and method of mounting, as well as of the effect of variation of the frequency of the sound The important consequences which may accompany a change in the state of a specimen are well illustrated by some results given for a cane fibre board 1 1 cm thick For a frequency of 1200 cycles per second it was found that the ratio of the absorbed energy to the incident energy was 0 07, when the board was drilled with 480 holes per square foot, each hole being 5/32 inch in diameter, this ratio was increased to 0 53

Jet-Wave Rectifiers —In a paper read to the British Association at Leeds in 1927, Prof Jul Hartmann described a jet wave rectifier he had invented for converting alternating current into direct current The alternating current flows along a thin jet of falling mercury which is put into synchronous oscillation with the current The end of the jet makes connexion alternately with two contact pieces connected with the opposite ends of a transformer winding The positive pole of the direct current is taken from the middle point of the transformer winding and the negative pole from the nozzle end of the jet The rectified current in the jet wave can be quite large, as mercury is a conductor The jet is cut by a tungsten knife placed between the two contact pieces The commutation is accompanied by a transient arc, and to reduce the energy losses in the arc was one of the main problems in designing the device The contact pieces are mounted in a chamber kept filled with hydrogen, because, with the possible exception of helium, this gas is the only one which is able to absorb the energy of the spark in the small time available for this to take place The duration of the spark in atmospheric air is about ten times as long as its duration in hydrogen Commercial rectifiers having an output of 200 kilowatts at 550 volts have been developed at the municipal power station of Copenhagen Experiments were tried on a large scale with a jet wave rectifier working in parallel with rotary converters Severe short circuits caused practically all the converters to fall out of action, but the jet wave rectifier continued to act during the short circuit and afterwards The author, in his paper to the Institution of Electrical Engineers read on Feb 13, points out that the jet wave rectifier provides a means for the production of very high direct current voltages at a reasonable cost He thinks that a 100 kilowatt direct current rectifier can be made from a hundred very simple jet wave commutators connected in series

Machine Telegraph Systems —Telegraphy and telephony are now comparable, as both can bridge the distance between two points on the earth's surface The valve amplifier with loaded conductors has done this for telephony, and the regenerative repeater, loaded conductors, and the valve have done it for telegraphy The paper, therefore, on machine telegraph systems which was read to the Institution of Electrical Engineers by H H Harrison on Mar 27 was a timely one He pointed out that although inland telegraphy, at least in Europe, is in a bad way financially, international telegraphy is remunerative In Europe, inland telegraphy is controlled by government departments, but in America, where it is successful, it is conducted by two privately owned companies The success, however, is mainly due to the fact that America is a land of long distances This and other economic factors enable the telegraph not only to survive but also to flourish in spite of the growth of its rival In Europe, a factor in favour of telegraphy is the difference in local times As we move eastward, an hour has to be added to the time for every 15° of longitude It is possible to telephone to America during normal business hours between 2 and 5 P M Greenwich time Talking eastwards must proceed in the morning, commencing at 9 A M, but it cannot be carried out farther east than China This difference in local time constitutes the only factor operating against world wide telephony The sole effect on telegraphy is to cause a change in the direction of the traffic, which flows eastwards and westwards alternately except when the working days overlap Either wired or radio telegraphy is bound to survive The most serious problem that remains to be solved is how to make inland telegraphs pay in countries where distances are comparatively short The principal obstacle is the cost of retransmission at the various stations, and this will probably be solved by making all these operations automatic

Turbo-Generator at Hell Gate Station, New York — There are many advantages in using very large turbine generators in central stations, and it is difficult to see what cause will ultimately limit their size Working steam pressures are also continuing to increase A pressure of 1200 pounds per square inch a few years ago was considered quite outside the practical working range Now it is well established and turbine builders are preparing for the coming of pressures up to 3000 pounds per square inch More than a year ago, a 165,000 kilowatt, two unit set was installed by Brown Boveri of Baden in the Hell Gate Station, New York In size it far outstrips all other electrical apparatus In the *Westinghouse International* for February, a description of this machine is given It is 91 5 feet long, 40 feet wide, and rises 27 5 feet from the floor It weighs 1300 tons, and would light a million homes at once or provide excellent illumination for a highway twice round the world A notable feature is the high speed of the rotor, which makes 1800 revolutions per minute Per unit generated it is more compact and cheaper than smaller turbines The necessary ventilation is provided by three vertical type blower fans which are placed below and between the generators This effects a considerable saving in the floor space No less than 275,000 cubic feet of air per minute are supplied to keep the electric generators cool when fully loaded Further details of this turbine are given in the *Brown Boveri Review* for January

Chemical Effects of X-rays —Clark and Pickett, in the February number of the *Journal of the American Chemical Society*, describe the action of X rays on several chemical systems known to undergo photochemical change in ultra violet light Most of the changes, if any, were very small The most sensitive reactions found besides the oxidation of ferrous to ferric salts were a series of aldehyde-ketone condensations Colloidal lead used in the Blair Bell technique for cancer therapy was studied from the points of view of preparation, stability, coagulation by X rays, production of secondary X rays, and catalytic effects in reactions subject to irradiation The conclusion was reached that the specific chemical effect rather than the action of producing secondary X rays *in situ* in the tissues is indicated

The *Snellius* Expedition

By Commander P. M. VAN RIEL, Chief of the Oceanographical Department, Royal Netherlands Meteorological Institute, Leader of the Expedition.

IN view of the lack of knowledge concerning the inland seas between Asia and Australia, the Society for Scientific Researches in the Dutch Colonies and the Royal Dutch Geographical Society at Amsterdam planned an oceanographical, geological, and biological expedition to those parts for the years 1929–30. The field of research, shown on the accompanying chart (Fig. 1), embraces the deep basins in the eastern part of the Dutch colonies with the adjacent regions of the Pacific and the Indian Ocean which they connect. The area is nearly as large as that of the Mediterranean and the Black Seas combined. The conditions are very different from those in the open ocean and render this part of the Archipelago a region of great interest for oceanographical, geological, and biological work.

In view of these joint interests the scientific staff is composed as follows: an oceanographer leader, with two oceanographers (one chemical, one physical), a chemist, a geologist, and a biologist. The scientific equipment of the research vessel (H.M.S. *Willebrord Snellius*, a surveying ship of 1200 tons) was transported while she was being built in Holland. By the co-operation of the East Indian Government and the Navy Department at Batavia, this ship is being withheld from her ordinary surveying work and put at the disposal of the expedition for fifteen months. The naval staff is composed of a commander, four naval officers, a naval engineer, a doctor, and a paymaster.

The main purpose of the expedition is to acquire more data concerning the physical and chemical properties of the sea water, the horizontal and vertical circulation in the various layers, the configuration of the bottom and its deposits, and the distribution of the plankton. Moreover, biological and geological investigations ashore and on coral reefs form part of the programme.

The investigations of ocean temperatures, the salinity and the amount of oxygen of the water, the determination of currents by calculation and direct measurements, and the meteorological observations directly connected with oceanography, are in charge of the leader of the expedition, assisted by Dr. H. J. Hardon and Mr. H. C. Hamaker. Commander F. Pinke and his officers and men are responsible for a considerable amount of work, of which echo soundings, the determination of the position of the ship, and laboratory work form the principal part.

The chemical investigations are in charge of Dr. A. B. Boelman. The determinations are to be such as will help and complete the oceanographical, geological, and biological work, not such as would be of purely chemical interest; hence determinations of salinity, oxygen content, alkalinity, and pH were chosen. The first is only of oceanographical, the second of both biological and geological interest. As already mentioned, these two are under the direct supervision of Dr. Hardon. Alkalinity measurements belong to the geological side, those of the pH to all three together. Up to the time of writing no opportunity had occurred for determinations of the phosphate content. It is hoped that it will be possible to make some phosphate determinations in the future, for these, together with quantitative plankton fishing, afford valuable information on the biology of the seas.

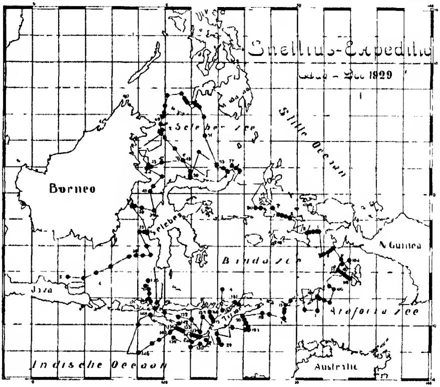

FIG. 1.

Data of importance for geology are obtained by the echo soundings that are made at frequent intervals during the sailing, and by wire soundings with a bottom sampler at each station. Dr. Ph. H. Kuenen, the geologist, is responsible for the latter.

The task of the biologist, Dr. H. Boschma, is confined to investigations which may help to give a better understanding of geological phenomena. At sea the biological work consists of the collection of plankton—surface catches at nearly every station, and, occasionally, catches with closing nets or large tow nets for macroplankton. Every now and then (twice or thrice a month) a couple of days are spent ashore together with Dr. Kuenen, then collections are made of the animals inhabiting the reefs and the shore. The results of the investigations ashore are mostly of local interest, but these observations

on reefs and reef islands will no doubt prove to be of more general importance when viewed as a whole

To the small number of existing wire soundings off the shelves many thousands of echo soundings are being added These will enable us to make corrections on the present depth chart

The track of the ship during the first five months is plotted on the chart (Fig 1), the dots representing the position of the stations In most cases observations have been made along cross-sections of the troughs between the isobaths of 200 m, so as to allow calculation of currents in various layers by the methods of dynamical oceanography

Interesting results have already been obtained concerning the physical and chemical properties of the sea water in the deep basins which are separated by rather shallow sills Direct current measurements have been made at two anchor stations (39° and 135°, depth 2300 m and 1200 m respectively), where the influence of the tide near the bottom was observed (135°) Moreover, investigations have been carried out at these stations concerning the variations in the properties of the sea water, probably due to internal waves

Optical Rotatory Power

THE Faraday Society's second General Discussion on "Optical Rotatory Power" was held in the rooms of the Chemical Society, Burlington House, London, on Friday and Saturday, April 25 and 26 In addition to English workers in this field of research, the Society had the pleasure of welcoming a large delegation of their foreign colleagues, from France, Germany, Italy, Belgium, and Switzerland The foreign guests included Prof R Betti (Bologna), Dr Bretscher (Zurich), Prof E Darmois (Paris), Dr R Descamps (Brussels), Dr Drucker (Leipzig), Prof P P Ewald (Stuttgart), Dr Werner Kuhn (Heidelberg) Mme Liquier Milward (a pupil of Prof Cotton, now resident in England), Dr R Lucas (Paris), and Dr K Wolf (Karlsruhe) Papers were also received from Prof G Bruhat and Prof A Cotton (Paris), and Prof R de Mallemann (Nancy), who were unable to attend the meetings

An introductory address by Prof Ewald on the physical aspects of optical rotatory power was listened to with interest, and will be read with still greater interest when it appears in print This was followed by a paper on "The Wave Mechanics of Optical Rotation and of Optically active Molecules" by Mr G Temple, of Trinity College, Cambridge Up to the present, wave mechanics has contributed but little to the theory of optical rotatory power, but it appears likely that the challenge provided by this discussion may result at no distant date in the development of a satisfactory method of formulating the older experimental results in terms of the newer theory At present, some confusion has arisen from attempts to identify the symmetrical and antisymmetrical forms of the molecule, as they exist in hydrogen and in ammonia, with the dextrorotatory and lævorotatory forms of an optically active compound Since these forms differ in energy content, they must therefore differ (at least slightly) in rotatory power This conclusion is, however, directly contrary to the well established postulates of Pasteur, and to the doctrine, held universally by all workers during the past hundred years, that enantiomorphism implies an absolute identity of properties, except when these are reversed in sign, but not in magnitude, by reflection in a mirror This anomaly is one that must be removed as soon as possible, if the newer theories are to prove their equality to or superiority over the old, and Dr Kuhn (whose simple model of an asymmetric molecule seems likely to provide a bridge between theory and experiment) has already suggested that, instead of being identified with the symmetrical and antisymmetrical solutions of the wave equations, the dextro and lævo forms should each be represented by a combination of these two solutions, with an appropriate difference of phase, so that the precise equality of the mirror image is restored

The theory of wave mechanics also postulates that all optical activity is unstable and only of transient duration, but without specifying whether the half-life period is to be reckoned in millions of years or in millionths of a second Under these conditions, it is impossible to check the theory against experiments, which have established the apparent permanence of optical activity, but, since racemisation (or the related phenomenon of inversion of one of a series of asymmetric carbon atoms, as in the mutarotation of the sugars) is so often found to depend on a catalyst, many physical chemists would envisage the process as one that occurs normally only in complex molecular systems, although the inversion of pinene vapour has been claimed as an example of an uncatalysed reaction The racemisation postulated by the theory of wave mechanics is therefore apparently a phenomenon of a different order from those which have been studied by chemists

Dr Werner Kuhn, who contributed a paper on "The Physical Basis of Optical Rotatory Power", has achieved unique success in deriving from theoretical physics results which are sufficiently simple to be of immediate practical value In particular, whilst Drude's simplified equation for rotatory dispersion is valid only in a region of complete transparency (his complete equation has not yet been tested against experiment), Kuhn's equation is valid right through the region covered by an absorption band Drude's equation has the merit of having made it possible for the first time to resolve the rotatory power of unsaturated compounds into partial rotations of high and low frequency, which are often of opposite sign, but this analysis is obviously less exact than that of Kuhn, and it is of interest to know that the discrepancy which the writer has observed repeatedly between the characteristic frequencies deduced from direct measurements of absorption and (with the help of Drude's equation) from measurements of rotatory dispersion, can be predicted from Kuhn's equation, in which this discrepancy does not occur

The three following papers, by Dr K Wolf, Dr H G Rule, and Prof R Betti, were all concerned with the influence of polarity on rotatory power, a subject on which Dr Rule has published a long series of papers in recent years Dr Wolf in a paper on "The Principle of Free Rotation in Optically Active Molecules" described the measurements which he has made of dipole moments, for example, of the active and meso forms of tartaric acid and its esters, in order to find out whether 'free rotation' occurs about the central bond He concludes that it does not, but this result can be attributed in some cases to the chemical effect of subsidiary valencies, and further experiments are contemplated on compounds in which this factor is unlikely to be operative Prof Betti, who contributed a paper on "Optical Rotatory Power and Chemical Constitution", has prepared a series of derivatives of the base, $HO\ C_{10}H_6\ CH(C_6H_5)\ NH_2$, and in order to eliminate the effects of rotatory dispersion, has calculated the 'absolute' molecular rotations of his compounds He has thus been able to establish a graphical relation,

first between the rotatory power of an alkylidene derivative, $HO\ C_{10}H_6\ CHPh\ N=CHX$, and the dissociation constant of the corresponding acid $X\ COOH$, and *secondly* between the rotatory power of the compound and its dipole moment One of his curves leads to the remarkable conclusion that, if the dipole moment were reduced to zero, the rotatory power of the compound would also disappear or become very small

In the section of the discussion dealing with apparatus and methods, only the paper of Dr Descamps on "Ultra violet Polarimetry" was communicated to the meeting

The papers of Prof Darmois and of Mme Milward dealt with the effects of neutral salts on the rotatory power of (1) tartrates and tartaric esters, (2) asparagine The tartaric esters always show a depression of rotatory power, but in the case of the salts an exaltation is sometimes observed These effects are attributed to the deformation of the tartaric radical, and to variations in the hydration of the tartaric ion In the case of asparagine, it was suggested that neutral salts act by turning the molecule into a *zwitterion*

$$NH_2\ C_2H_3(CONH_2)\ CO\ OH \rightleftharpoons \overset{+}{N}H_3\ C_2H_3(CO\ NH_2)CO\ \overset{-}{O}$$

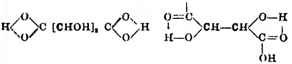
This effect was interpreted as depending on the polarisation of the molecule under the influence of ions bearing charges of opposite sign

Issues of a more controversial character were raised in the discussion of the origin of the variations of optical rotatory power in solution Measurements of rotatory dispersion have proved that the anomalous rotatory dispersion of ethyl tartrate can be expressed as the sum of *two* simple partial rotations of opposite sign, but, in order to explain the effects of temperature, Dr Lucas has had to assume the presence of *three* modifications of the ester He has also postulated that these may depend on the existence of three maxima of stability in the 'free rotation' of one half of the molecule relative to the other It was unfortunate that, in the absence of Prof G Bruhat and of Prof T S Patterson, the opposite view (which regards all the anomalies of tartaric acid as normal attributes of the molecule, HO CO CHOH CHOH CO OH) was defended only in writing Dr R Lucas had no difficulty in showing that the variations of rotatory power with concentration and temperature are not, as Bruhat suggests, theoretically incompatible with a dynamic equilibrium between various isomeric forms of the acid, since this deduction is only valid if the solvent is regarded (as in the early history of the theory of electrolytic dissociation) as equivalent to empty space It has also been established, by experiments on compounds such as ethyl acetoacetate and benzoyl camphor, that the equilibrium concentrations of dynamic isomerides are displaced by changes of solvent, perhaps in response to variations in the relative solubility of the various forms

In defence of Arndtsen's theory, that the anomalous behaviour of tartaric acid is due to the presence of more than one form of the acid, Dr P C Austin urged that the real problem is not so much to explain the existence of the anomalies, as to account for their complete disappearance in certain derivatives of tartaric acid which contain the complete electronic system of the acid, but with the addition of certain radicals, as in methylene tartaric acid or borotartaric acid Until some attempt is made to explain these well-established facts in terms of the normal structure of tartaric acid, it can be claimed that Arndtsen's hypothesis (even although it remains only a hypothesis) is the only one that covers the experimental data which are now available

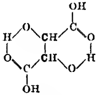
Some discussion arose as to whether the impedance of free rotation by the development of positions of maximum stability, as suggested by Lucas, would be sufficient to account for the variations of rotatory power of the different forms, and, in particular, for the reversal of sign that is required to explain the anomalous rotatory dispersion of tartaric acid and its esters According to van 't Hoff's theory of optical superposition, no change of rotatory power would be produced by free rotation about the central bond, but it was generally agreed that some modification of rotatory power might be produced by a mutual induction between the polar groups in the two halves of the molecule The writer expressed the opinion that, in view of the known tendency for carbonylic oxygen and hydroxylic hydrogen to interact (as pointed out by Pfeiffer in 1913 in the case of o hydroxy anthraquinone) it was unlikely that tartaric acid would be an exception to this rule It is therefore almost inevitable that isomeric forms of the acid should be produced according as the carbonyl radical interacts with the hydroxyl group of its own acid radical, or with one or other of the alcoholic hydroxyl groups, which are attached directly to the asymmetric carbon atoms, giving rise to systems containing rings of 4, 5, or 6 atoms, as follows

I II



4 atom rings 5 atom rings

III



6 atom rings

The proportions in which these would be present would depend on the relative stability of the various rings, and their rotatory powers would be likely to show greater contrasts than any that could be produced by the impedance of free rotation of the two halves of the molecule in formulæ I and II

The remaining part of the discussion, dealing with the chemical aspects of optical rotatory power, was largely non controversial in character Dr W H Mills gave an admirable account of the conditions under which molecular dissymmetry of the most varied type can give rise to optical activity His own study of impedance of free rotation by steric hindrance in the naphthalene series, following on Kenner's discovery of optical activity arising from a similar impedance in the diphenyl series, is of special interest as a case in which thermal agitation alone might suffice to produce a momentary removal of the constraint and so give rise to racemisation without the aid of a chemically active catalyst Dr J Kenyon then contributed two papers, on "Relations between the Rotatory Powers of the Members of Homologous Series", and, with Dr H Phillips, on "Some Recent Developments in the Study of the Walden Inversion", which also did not lead to any keen discussion, since they were mainly a record of well established facts

After the meetings in London, almost all the foreign guests made the journey to Cambridge, where a

reception was given in the Laboratory of Physical Chemistry, at which Prof and Mrs Wiegner of Zurich were also present In addition to exhibits of polarimetry, refractometry, ultra violet and infra red spectroscopy, photochemistry, electron bombardment, molecular rays, and a number of exhibits in branches of physical chemistry less directly related to optical rotatory power, the adjoining Magnetic Laboratory was thrown open to inspection by permission of Sir Ernest Rutherford, and Dr P Kapitza was able to show the production of liquid and solid hydrogen, which has been suspended in Great Britain since the death of Sir James Dewar T M LOWRY

Archæology and Bible History

PROF JOHN GARSTANG'S Friday evening discourse on "The Historicity of the Books of Joshua and Judges" delivered at the Royal Institution on May 9, apart from the intrinsic interest of any topic relating to the archæology of the Bible, was notable as affording some further examples of the way in which recent archæological investigation has served to confirm tradition The discovery of evidence in Mesopotamia tending to substantiate the authenticity of the story of the Flood in the Bible and in Sumerian legend is a case in point, and Prof Garstang himself referred to the confirmation of the Homeric account of Achæan activities in Asia Minor afforded by recent Hittite discovery

Repeatedly when visiting sites under excavation in Palestine since the War, Prof Garstang has been deeply impressed by the sense of material reality underlying the narrative in the Books of Joshua and Judges It is now generally agreed, as the result of critical textual study, that these books in their present form were composed and amplified by various schools throughout a period of seven hundred years For the purpose of his discourse, Prof Garstang dealt only with the archæological problems raised by the older portion of the text, and it was with the specific object of studying these problems that his excavations at Jericho, Ai, and Hazor were undertaken in 1928 In addition he revisited every identified site mentioned in the oldest sources No radical flaw was found in the topography and archæology of these documents

The results of Prof Garstang's investigations as summarised in his discourse are of profound interest and of singular significance in their bearing upon the historicity of these Bible narratives All the identified sites mentioned in Joshua and Judges i to v, such as Gezer, Megiddo, Bethshean, and Hazor, flourished in the Bronze Age, and for the most part were positions of strategic importance The names of no less than twenty four cities of the Canaanites in the age of Joshua are identical with those mentioned in the annals of Pharaohs of the xviiith Dynasty, especially from Tothmes III to Akhenaten, that is from 1475 to 1375 B C Among the cities which the Israelites could not capture were Bethshean, Megiddo, Acco, Gezer, Jerusalem, and Gaza These are found to be organised centres of Egyptian authority It thus becomes clear that the background of the exploits of Joshua was that disclosed by the Egyptian records of the fifteenth century B C

Prof Garstang's excavations at Jericho, Ai, and Hazor in 1928, and further investigations at Jericho early in the present year, fully bear out this interpretation It has been found that each site shows traces of destruction near the middle of the late Bronze Age or about 1400 B C Ai and Hazor were abandoned as from that time, and Jericho was not rebuilt for centuries At Bethel and Debir layers of destruction have been disclosed which are to be dated at the end of the fifteenth century Bringing these results into relation with the tradition that the Exodus took place 480 years before the building of Solomon's temple, that is, about 1447 B C, the date of Joshua's invasion of Canaan would fall about 1407 B C This tradition has been mistrusted, but if the later additions to the Book of Judges are disregarded, the discrepancies disappear

Thus, Prof Garstang concludes, all available archæological and literary evidences point to the same date in the middle of the late Bronze Age, and the historical and topographical allusions in the Books of Joshua are found to be in accord with the material results of investigation Further, Israel's position under the Judges falls into the frame afforded by Egyptian chronology and the record of Egyptian relations with Canaan The records of both books were founded on fact

University and Educational Intelligence

BIRMINGHAM - The University having been associated with the Birmingham General Hospital as constituting the Birmingham centre of the Radium Commission, 1 gm of radium has been lent by the Commission to the General Hospital and 0 5 gm to the University The radium lent to the University is to be used for the production of radium emanation (radon) and a small building for this purpose is being erected as part of the Physics Department under the control of the Poynting professor of physics, Prof S W J Smith The radon produced is to be distributed to all hospitals which are at the present time recognised by the Faculty of Medicine as teaching institutions connected with the University Certain other institutions in the area, on making application to the Faculty and furnishing evidence of suitability, will also be supplied

CAMBRIDGE —Dr W E Dixon, of Downing College, has been reappointed reader in pharmacology

MANCHESTER —A bronze plaque of the late Prof W H Perkin, presented by former students and friends, will be unveiled in the Chemistry Theatre of the University on Saturday, May 24, at 11 A M, and friends of the late Prof Perkin are invited to be present

The Council has accepted the offer of Mr James Grier and Mr Harry Brindle to institute two silver medals in pharmaceutics The medals will be offered annually for competition to the students of the chemist and druggist course and of the pharmaceutical chemist and B Sc in pharmaceutics courses

OXFORD —The sixth annual report of the Lewis Evans Collection was presented to Convocation on May 6 by the curator, Dr R T Gunther, of Magdalen College It contains an account of the restoration work on the Old Ashmolean Building which has been carried out by the University Chest, and records the installation of the new armorial windows on the main staircase A long list of accessions to the Collection is included, and the report goes on to point out that if the original 'Officina Chemica" in the basement, at present used for the storage of books, could be made available, it would be possible to refit "the most historic laboratory in Britain with its own apparatus", much of which was used there by Charles Daubeny a hundred years ago The report ends with a record of the lectures and research work undertaken and the publications issued during the past year, together with a note as to the financial needs of the Collection

On the motion of Dr F W Pember, Warden of All Souls', Congregation has passed a decree authorising a grant of £50 towards the expenses of an expedition organised by a body of undergraduates who propose to make during the present year an ecological survey of Lapland and western Norway

Historic Natural Events

May 18, 1680 Hailstorm in London —According to Dr Hooke, about 10 30 the sky grew very dark and there was thunder, very near Soon after there began to fall "a good quantity of hailstones, some of the bigness of pistol bullets, others as big as pullets' eggs, and some above 2½ inches and near 3 inches over the broad way, the smaller were pretty round, and white like chalk or sugar plums, the others of other shapes"

May 18–19, 1888 Thunderstorms —On the night of May 18–19, a thunderstorm passed across England and southern Scotland from south to north at the rate of 50 miles per hour On May 19 there was a series of isolated thunderstorms In Glasgow the storm was described as 'the most awful occurrence of the kind which has been recorded in the annals of the Observatory' It was accompanied by torrential rain and hailstones as large as pigeon's eggs Much damage was done by lightning in several parts of the country, and people were killed at no fewer than ten different places in southern Scotland and northern England

May 19, 1780 'Black Friday' or The Dark Day' – In New England on May 19, 1780 the sky was cloudy and the sun was just apparent and of reddish hue in the early morning Then it rained slightly and thundered and the darkness grew, so that large print could not be read, nor could business be transacted Schools were dismissed, and all work ceased Fowls went to roost as at night, frogs began to pipe, night birds sang and cocks crow The darkness began to clear at 1 30 P M and by 3 15 P M the light was as usual for a thick cloudy day

May 19, 1809 Hailstorm in London —A violent thunderstorm began about 5 P M accompanied by hailstones an inch in diameter Carried by a strong south wind, they destroyed a great number of sky lights and south windows, and collected in great drifts The stones travelled with such speed that they left clean round holes in the glass, like bullet holes

May 19, 1811 Whirlwind near Sheffield — A whirlwind, accompanied by hailstones up to five inches in circumference, tore up seven trees by the roots broke others in the middle, and unroofed many buildings Nearly all the water was carried out of a mill dam and dispersed in the air

May 21, 1846 The Beginning of the Notably Hot Summer –This date was the beginning of the Notably Hot Summer' and severe drought which continued until Sept 23 From the effects of this amazing summer, many horses and some men died, and many kinds of provision were much spoiled, whether bread, meat, cheese, butter, ale or wine, and many other articles were greatly injured The corn harvest was very early, and the wheat crop good This was, for continuance, the hottest summer since 1780, if not since 1750, but 1818 and 1826 were rather similar

May 21, 1890 Refraction Phenomena —The rising sun at Brunn in Bohemia was observed to take a series of remarkable shapes before it finally rose well above the horizon and became circular The earliest form was a conical tower with a flat cap, changing through cylindrical to urn shaped The next stage showed the form of a mushroom complete with a short stem, and finally the stem became detached and gradually disappeared The whole series of changes occupied eight minutes

May 24, 1681 Drought —Under this date Evelyn records 'There had scarce fallen any rain since Christmas" On June 11 he adds, "It still continued so great a drought as had never been known in England In the Rector's Book of Clayworth, Notts, June 18 "Barley found dry in ye fields, having lain so, ever since sowing time", and in his summary of the year It was a very dry and drought year fro ye beging of April [the Rector's year began on April 1, old style] to yo 20th June, not having raynd, except on ye 7th of May" At Towneley in Lancashire the rainfall this year was only 76 per cent of the average

May 24, 1783 Dust Haze From May 24 until almost the middle of August there was an unusually dense and very persistent high fog over the whole of Europe Asia Minor, Syria, Iceland, and many other countries This was probably due to volcanic dust from the eruption of Laki, Iceland The weather was greatly disturbed in Europe there was a persistent southerly wind and great heat and the Nile flood was abnormally low The following winter 1783 84, was very long and very rigorous over the whole of Europe and in North America Gilbert White records hard frost so late as April 2

Societies and Academies

London

Physical Society, May 9 **E J Williams** (1) The induction of electromotive forces in a moving liquid by a magnetic field and their application to the investigation of the flow of liquids Preliminary experiments on the flow through straight tubes show that potential differences of the order of 10^{-4} to 10^{-8} volt set up by a magnetic field in a moving liquid consisting of an aqueous solution of copper sulphate can be satisfactorily measured —(2) The motion of a liquid in an enclosed space The increase of resistance of a column of mercury in a magnetic field is due to the internal motion of the liquid produced by the action of the ampere forces between the magnetic field and the electric current traversing the mercury The hydrodynamic significance of the results of such experiments is considered, e m f 's as small as 10^{-8} to 10^{-7} volt induced by a magnetic field in moving mercury, can be accurately measured —**E Simeon** The generation of sound by the siren principle The paper discusses various undesirable features of the simple siren considered as a sound source for technical work, and describes a siren with a reasonably pure note, the intensity of which can be kept constant throughout a range of pitch from about 70 to about 7500 cycles —**L Hartshorn** Surface resistivity measurements of solid dielectrics The paper describes (1) a new form of electrode suitable for surface resistivity measurements on insulating materials in sheet form, and (2) a method for the determination of the 'volume leakage' correction for any system of electrodes Data are given on the volume leakage correction for the various types of electrode in general use, and on the leakage resistivities' of materials commonly used in the construction of laboratory instruments

Paris

Academy of Sciences, Mar 31 —**Mesnager** Must the solution of the problem of the cylinder given by Saint Venant sometimes be rejected? A criticism of a recent communication by Henri Villat and Maurice Roy Without questioning the mathematical work, the author is not in agreement with the practical interpretations deduced —**Marcel Brillouin** Dynamical tides with continents The law of depth and the attraction of the ring —**C de La Vallée Poussin** The conformal representation of plane areas multiply connex —**Paul Pascal and René Lecuir** The chemical and magnetic study of complexes derived from the triazine nucleus —**A Tonolo** A physical interpretation of the tensor of Riemann and of the principal curvatures of a

variety V_2.—**Mohamed A. Haque**: The magnetic double refraction of ethyl alcohol, of water and of aqueous solutions of nitrates.—**F. Baldet**: Observations, with the large Meudon telescope, of the celestial body discovered at the Lowell Observatory. A trans-Neptunian planet, with the distance and diameter given by the discoverers, should shew a planetary disc of about 1·0", of the same order of magnitude as the satellites of Jupiter, and this should be easily visible with the large telescope of the Meudon Observatory (83 cm. objective), which has a separating power of 0·17". Observations on four days, one under exceptionally good conditions, failed to shew any trace of a disc.—**E. Henriot** and **Mlle. A. Marcelle**: The direct measurement of the ratio of the absolute retardations in double refraction by deformation.—**B. Bogitch**: The preparation of blue glass and the decomposition of sodium sulphate by silica.—**M. Prettre** and **P. Laffitte**: The inflammation and combustion of carbon disulphide. For percentages of carbon disulphide vapour varying between 1·3 and 34·0 by volume, the temperatures of inflammation vary linearly between 138° C. and 338° C. For mixtures containing more than 10 per cent of carbon disulphide, luminescence of the gaseous mixture is observed before inflammation, but this is always less intense than that observed in the case of carbon monoxide. In all the experiments there was noticed a slight brown deposit on the walls of the apparatus: this was shewn to be the monosulphide, CS or a polymer.—*Marcel Godchot* and **Max Mousseron**: New methods of formation of 2: 5 dimethyl piperazine. Three new methods are given, the first two starting with 2: 5 dimethylpyrazine: catalytic reduction with hydrogen in presence of nickel at 150°-160° C., reduction with hydrogen in acetic acid solution with platinum as the catalyst: the third method, the simplest, is the reduction by hydrogen in presence of platinum in acetic acid solution of isonitrosoacetone.—**F. François**: The action of selenoxanthydrol on ureas and carbamic esters. The typical reaction between xanthydrol and ureas and carbamic esters occurs when the oxygen of the pyrane nucleus is replaced by sulphur or by selenium.—**Paul Gaubert**: The dehydration of heulandite.—**Henri Vincienne**: Stratigraphical and tectonic observations on the southern termination of the Crédo chain.—**Henri Mémery**: The winter of 1930 and solar activity.—**H. Buisson, G. Jausseran,** and **P. Rouard**: The transparency of the lower atmosphere. The results of direct measurements of atmospheric absorption over distances of 600 metres and 2500 metres for wave-lengths varying from 5780 to 2482. It is hoped to extend the results to smaller wave-lengths.—**Link** and **Hugon**: Direct measurements of atmospheric absorption.—**V. N. Lubimenko** and **Mme. Rauser-Černooussova**: The fossil remains of chlorophyll in marine mud deposits. Observations published in 1921 suggested that the pigment of chlorophyll, in the absence of oxygen, possesses great stability and might be preserved as a fossil substance. Results are given in the present paper confirming this view. Four specimens, of varying age, one belonging to the Tertiary age, gave alcoholic extracts containing chlorophyll, as shown by spectroscopic examination.—**Jakob Eriksson**: The hibernation of *Puccinia Ribis* is the vegetative state in the winter buds of the plant acting as host.—**J. des Cilleuls**: The phytoplankton of the Loire in the course of the summers of 1928 and 1929. Owing to the exceptional warmth and dryness of the summers of 1928 and 1929 the plankton of the Loire was unusually abundant, recalling a lake regime. Analogous observations were made on the plankton of the Elbe, near Dresden, and also near Hamburg, during the dry summer of 1904.—**Pierre Dangeard**: The mobility of certain cells of *Porphyridium cruentum*.—**Raymond-Hamet**: The physiological analysis of the intestinal action of Uzara.—**Georges Truffaut** and **V. Vladykov**: The microflora of the rhizosphere of wheat.—**J. Vellard**: Antivenomous vaccination. Results of experiments on the production of vaccines exerting a protective action against the bites of poisonous snakes.—**J. André Thomas**: A neoplasic reaction due to the degenerescence of the ovocytes and sometimes of the bristles in *Nereis diversicolor*. The formation of conjunctive tissue from the newly formed amibocytes.

ROME

Royal National Academy of the Lincei, Jan. 19.—**T. Levi-Civita**: Characteristics and bicharacteristics of Einstein's gravitational equations (2).—**U. Cisotti**: Dynamic actions of circulatory currents around a bilateral strip or an arched strip. The considerations advanced in an earlier note are illustrated by two concrete examples.—**V. Nobile**: Intermediary trihedra of reference for stellar dynamics; criteria of choice.—**L. Cambi** and **A. Cagnasso**: The reactions between ferrous compounds and nitric oxide (2). Nitric oxide undergoes association with ferrous salts having anions of slight electro-affinity and of a high degree of oxidisability (such as the carbonate, hydrogen carbonate, and acetate), giving first nitroso-salts with groupings (NO') having a halogen-like function unlike that of hyponitrous acid, into which such groupings undergo subsequent transformation. This transformation is effected by decomposition with silver salts in a neutral or feebly acid medium, or by a sufficient increase of the pH value, such as is caused by addition of excess of the alkali salt of the same acid as is present in the ferrous salt used.—**R. G. Harrison** and **P. Pasquini**: Grafting experiments with *Clavelina lepadiformis* (Muller).—**L. Petri**: Experimental reproduction of *mal del secco* of lemons. This disease, which causes serious damage to lemon plantations on the eastern coast of Sicily, is the result of attack by two distinct fungi. The wood is first attacked by *Deuterophoma*, which causes tracheomycosis or adromycosis, which is shown externally only by partial or total yellowing of the leaves and cortical tissue. This primary phase of the disease renders possible subsequent antracnosis of the buds and young branches, the cause in this case being infection with *Colletotrichum glœosporioides* Penz. The disease may be produced by artificial inoculation with the two organisms.—**Rina Baldoni**: Systems of principal normals to a variety at its π_2 (1).—**S. Cherubino**: A general theorem on real Abelian varieties.—**N. Cioranescu**: Approximation of a function by another function belonging to a given linear functional, and approximation of any vectorial field by an irrotational field.—**H. Lewy**: The unicity of the solution of Cauchy's problem for an elliptical equation of the second order in two variables.—**A. Lusis**: Investigation of the permutable functions of the first species with a given function.—**Maria Cibrario**: The non-existence of congruences W of certain hyperspacial straight lines.—**R. L. Gomes**: Isoenergetic movements.—**B. Finzi**: Dynamic actions relative to plane irrotational currents of viscous liquids. The analytical formulæ recently deduced are applied to the determination of the dynamic actions exerted on a rigid profile enclosed by a regular current.—**G. Viola**: Fluctuations of the light curve of U Cephei. The various hypotheses capable of explaining this phenomenon are discussed.—**G. Scagliarini** and **P. Pratesi**: Potentiometric determination of alkaline sulphides. The interaction of sodium nitroprusside and an alkaline sulphide results in the formation of a complex salt comprising one molecule of each of the reagents. Investigation of the curve of electrometric titration of

decinormal solutions of the two compounds reveals a well marked point of flexion corresponding with equivalence of the solutions This result furnishes the basis for a method of determining sulphides, even in the presence of large proportions of other salts —Z Jolles and J Krugliakoff Investigations on diazo hydrates, azoxy compounds, and nitrones It was recently found that normal diazohydrates exhibit all the properties characteristic of an energetic oxidising agent Further experiments show that the same is the case with the analogous compounds, α and β azoxy compounds, nitrosophenylhydroxylamine, and nitrones —M Anelli A geological section of the Reggian Apennines — G B Cacciamali Problems of Lombardy tectonics (with reference to investigations on the sub soil) —S Di Franco The lava from the eruption of Etna in 1928 Study of the different lavas of Mount Etna shows that these may be grouped into seven types The lava from the eruption of 1928 is dark grey, tending to reddish, and moderately heavy, and is analogous microscopically to those of the later eruptions and also to some of the older ones It contains pheno crystals of plagioclase, augite, and olivine, disseminated in a basic mass composed of plagioclase, augite, magnetite in abundance, and vitreous substance in small proportion It belongs to type III of the author's classification —G Mezzadroli and E Vareton Further investigations on the action exerted by a radio oscillator for ultra short waves (2 3 metres wave length) on the germination of seeds and on the growth of plants (2) Experiments on cotton, beans, peas, and maize show that when seeds and plants are subjected to the action of these waves, the germinators being placed between the coils of the receiving oscillating circuit, the effect is even greater than that observed with an interposed Lakhovsky oscillating circuit or with systems of Lecher wires in the zone of greatest intensity

The Radcliffe Observatory and its Proposed Removal

THE British National Committee for Astronomy of the International Research Council has pronounced definitely in support of the proposal to transfer the Radcliffe Observatory, Oxford, to South Africa, rather than to another site in England This was the view taken at a meeting of the Committee held on May 9, when it was also resolved "that the establishment in South Africa, under English control, of a new observatory equipped with a large reflector, and adequately endowed, would not only be in the best interests of astronomy, but is almost an imperative necessity in the interests of British scientific prestige" The resolution appears in full in our correspondence columns this week over the signatures of sixteen of the seventeen members of the Committee present A glance at the list of names should be sufficient to convince anyone that leading astronomical opinion in Great Britain is decidedly in favour of carrying on the scientific work of the Radcliffe Observatory in South Africa instead of continuing it in England

Dr John Radcliffe, whose name the Observatory bears, was a successful Court physician who died in 1714 leaving a fortune estimated at £140 000 His will provided for the building of a library in Oxford and the salary of a librarian, for travelling fellowships, for rebuilding the front of University College, Oxford, and some other purposes When the bequest of £40 000 allocated to the library became available upon the death of Radcliffe's sisters, the trustees built the Radcliffe Library and later the infirmary The residue of the real and personal estate remaining after the payment of various legacies and bequests was to be used by the trustees for "such charitable [purposes] as they in their discretion shall think best" There is no mention of astronomy in Radcliffe's will, and it was not until more than fifty years after his death that the trustees decided that the practical study of this science might be regarded as a charitable purpose and that they could therefore make provision for it

The Savilian professorship of astronomy was founded in 1619 by Sir Henry Savile, Provost of Eton Shortly after Dr Hornsby succeeded to the chair in 1762, he appealed through the Chancellor of the University to the Radcliffe trustees for funds for an observatory, and in 1771 they secured a lease (and in 1820 the freehold) of nearly nine acres for the building and grounds adjoining the Radcliffe Infirmary, which was opened a year earlier Shortly afterwards the building was put in hand, the trustees

having previously agreed to purchase the instruments suggested by Hornsby These were completed and delivered in 1773 and are still in the observatory The building was not, however, finished and furnished until towards the end of the eighteenth century Several additions have since been made, including a building for an equatorial telescope in 1903

From the foundation of the Observatory until 1839 the Savilian professor and Radcliffe observer was a joint office, but the University then elected a successor to Dr S P Rigaud without consulting the Radcliffe trustees, with the result that the trustees appointed an observer of their own, and the chair of astronomy has since then been separated from the post of Radcliffe observer

The trustees then asserted their independence, as they can in their discretion with the sum which will be at their disposal if the Charity Commissioners consent to the proposed sale of the present site of the Radcliffe Observatory for the use of the Radcliffe Infirmary As the Observatory has been in existence for more than 150 years, it is reasonable to assume that astronomy has a substantial vested interest in the sale of property which it has possessed for so long a period It seems too late now to urge that as astronomy is not mentioned in Radcliffe's will, the sum available from the sale of the Observatory site should be used for other than astronomical purposes Probably the trustees will give consideration to any such claims which may be advanced, but it scarcely seems possible now to dispute their legal right to continue to use for astronomy the benefaction which they have administered for so long for the promotion of that branch of science

Assuming, therefore, that the trustees have a substantial sum at their disposal, there seem to be two points of view as to how this might be used—one that of Oxford itself and the other that of science, which knows no geographical limitations and welcomes facilities for increase of natural knowledge anywhere It must be acknowledged, of course, that every scientific department at Oxford could make good use of the fund for the development of fields of inquiry which they are unable to explore because of lack of resources, but we wonder whether any department would be inclined to hand over to a separate branch of science an endowment which it had held for a century and a half In comparison with other subjects, astronomy is very poorly endowed in Great Britain or the British Empire The suggestion that it might now transfer to other departments of science one of its few endowments cannot, therefore, be seriously entertained

The position at present is that the Charity Commissioners have the proposed sale of the Observatory site under consideration Even if consent is given, the future site of the Observatory cannot be definitely settled for many months yet The present intention of the Radcliffe trustees, for which they hope to obtain legal sanction, is to move the activities to a site on the high veld in South Africa, in view of the excellent observing conditions there and the pressing need of more work on the southern stars Dr Steavenson is at present testing the seeing at a site outside Pretoria, using the same method as is being employed in the search for a site for the 200 inch reflector in California If the Observatory goes to South Africa, it is planned that it should be equipped with as large a reflector as the trust can afford, possibly a 72 inch, as there is an immense field of spectroscopic work, which such a telescope alone can do, awaiting to be done to complement similar work in the northern hemisphere

From the point of view of progress of astronomical science, the advantages to be gained by the establishment of an observatory in South Africa are beyond dispute Practically all the most important astrophysical work is now done with large reflectors, like the 72 inch telescope used by J S Plaskett at the Dominion Astrophysical Observatory, Canada His work on the rotation of the galaxy and the interstellar cloud especially needs to be extended to the southern sky

It would be easy to mention many other profitable lines of work for which a large reflector is required in the southern hemisphere, and also where observing conditions are more favourable than in England All observing work requiring long exposures, and all photometric work, is carried on here with difficulty and disappointment on account of uncertainties of weather, and this is harder on large telescopes than on small It is indeed unnecessary to labour the point that a big reflector is urgently needed for line of sight and other spectroscopic work, and that from many points of view the most appropriate site for such an instrument is on the high veld in South Africa, where the American universities of Harvard, Yale, and Michigan, as well as the Smithsonian Institution, have already established observing stations, and where the University of Leyden is also to have an observatory through a grant of £20,000 from the Rockefeller Institute

There should be no difficulty in arranging for a close relationship between the University of Oxford

and the Radcliffe Observatory wherever it may be The University has an observatory of its own, and the professor of astronomy, Prof H H Turner, strongly advocates the proposed removal of the Radcliffe Observatory to South Africa Such an outpost where young English astronomers could go for experience, and to which the professors at Oxford might send students, would be most useful, and friendly co-operation of this kind between the University and the Radcliffe Observatory would be easy to establish A good deal of the measurement of spectroscopic and other photographs could no doubt be carried on at Oxford, leaving the astronomers at the Observatory in South Africa free for observational work Oxford has received so much from South Africa that it might now appropriately welcome the transfer to that country of an observatory which cannot usefully extend its work under present conditions, either of site or of instruments Existing work would, of course, be continued before the removal took place We understand that if and when the sale of this site is completed, the Radcliffe trustees will take a lease for five years of the observatory buildings and part of the grounds to enable the completion of the programme of work on the proper motions of faint stars in the Kapteyn selected areas (about 30,000 stars are involved) started by Rambaut twenty years ago The actual observatory buildings would remain as a brilliant example of classical architecture, it is Sir William Morris's wish that they should be used for post graduate work in connexion with the University School of Medicine

Theoretical and Applied Colloid Chemistry

(1) *Elektrochemie der Kolloide* Von Prof Dr Wolfgang Pauli und Dr Emerich Valkó Pp xii + 647 (Wien Julius Springer, 1929) 66 gold marks

(2) *Die Kolloide in Biologie und Medizin* Von Prof Dr H Bechhold Funfte vollig umgearbeitete Auflage Pp xii + 586 + 7 Tafeln (Dresden und Leipzig Theodor Steinkopff, 1929) 32 gold marks

(3) *Équilibres superficiels des solutions colloïdales études de biophysique moléculaire* Par Dr P Lecomte du Nouy (Monographies de l'Institut Pasteur) Pp 228 (Paris Masson et Cie, 1929) 32 francs

(1) THIS imposing volume attempts, as the preface states, to base an electro-chemistry of colloids on the modern theories of electrolyte solutions It is the outcome of careful investigations continued for many years, beginning with proteins and gradually extended to many inorganic sols

The book falls into three main sections an introduction, which is a concise summary of the relevant chapters of modern physical chemistry, a general and a special electro chemistry of colloids The second section, after describing the preparation and purification of sols as well as their coagulation by electrolytes, proceeds to develop the principal theses of Pauli's theory Suspensions and colloid particles behave like electrolytes of very high molecular weight The particle consists of a neutral portion forming its main bulk, composed of insoluble and non dissociating molecules, and a small 'ionogenic' portion which is, generally speaking, a true complex compound in Werner's sense The ionogenic complex dissociates into two sets of ions, one of which is held to the neutral portion by chemical forces and imparts the charge to it, while the other forms what Pauli calls the 'counter ions' The particles may be 'isomolecular' when the neutral and the ionogenic part have the same composition, for example, in silicic acid

$$[x(SiO_2 + nH_2O)\ yHSiO_3] + yH^+$$

or 'heteromolecular', when the two parts differ in composition, as in ferric hydroxide sol

$$[x(Fe_2O_3 + nH_2O) + yFeOCl\ FeO^+] + Cl^-$$

Pauli does full justice to the earlier work of J Duclaux, who arrived at a somewhat similar 'chemical' theory by combining conductivity measurements with determinations of osmotic pressure Pauli considers the latter liable to many errors and substituted for them electrometric measurements, he also investigated sols much more highly purified by prolonged dialysis, and especially by electrodialysis than those studied by earlier workers The record of this large mass of minutely careful quantitative work deserves the most careful study To obtain complete insight into the constitution of the ionogenic complex, it is necessary to combine with the electrical methods chemical analysis, which also calls for a highly developed technique

Even this complete armoury, however, fails in some cases It is a little disappointing that it should do so with the gold sols which at first sight might seem ideal for testing the claims of Pauli's theory and its chief rival, the adsorption theory The constitution of the ionogenic complex is not definitely known, but Pauli assumes it to be an aurate or auric acid, the anion of which gives the particle its negative charge Zsigmondy and his school, on the other hand, consider that it is due

to the adsorption of OH ion On either assumption the disperse phase should contain oxygen, but careful analyses of the coagulum by both parties has failed to find any Pauli argues that the composition of the coagulum is not that of the stable particles, and that his view receives support from the analogy with hydroxide sols and more directly by recent work on platinum sols Of the adsorption theory in general he says that it "cannot be considered more than a description" Still, it seems difficult to account for the negative charge on the particles of 'pure oil water' emulsions otherwise than by the adsorption of OH ions, since no other anions are available

The reviewer must confess to a slight feeling of disappointment—probably unreasonable—on reading the application of the authors' theory to the fundamental problem of the electrolyte coagulation of lyophobic sols To attempt a theory of the stability of sols would, they say, be premature, as we have no theory of solubility, of which the stability of colloids is a special case It looks as if the experimental fact that colloidal anions, that is, negatively charged particles, give a coagulum with all cations had to be accepted like the fact that electrolytic anions give precipitates with specific cations, for example, SO_4'' with Ba The adsorption theory put forward by Freundlich to account for the valency effect is rejected by the authors, without any very clear alternative, on two grounds the empirical nature of the adsorption isotherm and the impossibility of proving that different ions are adsorbed to the same extent

It must be confessed that these doubts as to the adequacy of the authors' theory to solve all the long standing problems of colloid chemistry do not strike the reader until some time after he has finished studying their book The first impression is profound, such as a vast generalisation naturally produces on the student of a subject which has, perhaps, led a somewhat hand to mouth existence in the way of theory, a generalisation, moreover, supported by a vast array of experimental work, the implications of which are developed and argued with extreme acuteness Sometimes, indeed, the authors go beyond what the facts seem to warrant, as in a notable passage (p 296) headed "The Validity of Faraday's Law", and beginning "Faraday's law of equivalent separation naturally holds for the electrolysis of colloidal electrolytes too, provided it is referred to the products separating at the electrodes or escaping as gas On the other hand, it does not necessarily hold for the gel which separates" If the reader, quite reasonably, hopes for even a few instances which permit quantitative verification of the law and would thus provide the most striking evidence possible for the theory, he is doomed to disappointment, since a very detailed discussion of the secondary effects leads to the conclusion that a quantitative verification is scarcely to be expected

Whatever the quantitative evidence, however, it will in the end probably depend on the reader's bias whether he considers that a great attempt to develop a single theory of the constitution of aqueous sols, which excludes adsorption even as an ancillary factor, has succeeded or, indeed, can be completely successful It is certain that everyone seriously interested in the subject will have to study this book, which puts the case for the purely chemical' view with extraordinary ability and, where it becomes controversial, with perfect fairness and good temper

(2) The second edition of Bechhold's well known work appeared in 1918 and was twice reprinted without alterations The present, fifth, edition has been entirely re written, a course which has become unavoidable in view of its purpose, "to apply the results of the investigation of colloids to biology", and the enormous amount of new work done in this field in the last ten years

A short introduction to colloid chemistry forms the first part of the book The second, headed "Biocolloids", deals first with the colloidal constituents of organisms—the carbohydrates, lipoids, and proteins—and then with foods and drinks, enzymes and immunity reactions, giving a clear survey of these subjects in some 80 pages

The third part is probably the most interesting, certainly to the reader who is a student of colloids rather than of biology Assuming what nobody will contest, that living organisms must be built up from colloidal material, the author goes on to say that "Colloid and water in the organism are *one*, an organism free from water is lifeless" It is indeed in this point, the retention, distribution, and elimination of water by organisms, that colloid chemistry has contributed most materially to the elucidation of biological problems It is not necessary to recall how the theory of osmotic pressure was hailed, and even largely developed, by biologists, and how soon it failed to explain things such as—to take one example out of many—the rapid death of marine organisms in pure sodium chloride solutions isotonic with sea water We now know that the water content of organisms or of living tissues is not regulated merely, or even largely, by osmotic equilibria, but also by the specific effects of ions,

effects which manifest themselves equally in the swelling of non living and structureless material like gelatin, and have been investigated largely by this means

How far-reaching are the applications of these experimental results is shown by a very large number of examples under the sub headings dis tribution of materials and metabolism, growth, form and development, cells and tissues, respiration and circulation, resorption, secretion and excretion, and nerves Notwithstanding the large amount of literature drawn upon, the author is not content to give abstracts but always preserves a critical attitude The reviewer (with recollections of papers on " The Viscosity of Protoplasm " in his mind) is entirely in sympathy with the author's strictures on the use of the term to describe the contents of any cell, and with his comment " In looking for the *common* properties of the different protoplasms, one substitutes a uniformity which certainly does not exist, and overlooks the differ ences "

The fourth and last part is devoted to toxicology, pharmacology, and therapy, and to microscopic technique Among many other interesting sub jects it discusses the therapeutic effects of colloidal metals, which still seem to lack a complete explana tion The chapter on microscopic technique gives a good survey of the present theories of staining with due reference to the work of the Prague school

An unusually complete name index and an adequate subject matter index add to the value of the book It should have a stimulating effect on colloid chemists and provide those who have ambitions beyond further investigations on the co agulation of gold or arsenic trisulphide sols with a vast number of fascinating problems

(3) This is a practically unaltered translation of a work published in English under the same title in 1926 and reviewed in NATURE of April 9, 1927, vol 119, p 523 E H

Buckman's Type Ammonites

Type Ammonites VII By the late S S Buckman With Editorial Note, Chronological and other Tables and Index, by Dr A Morley Davies Parts 71-72 (combined) Pp 15-78 (London Thomas Murby and Co, 1930) 20*s*

THE death of S S Buckman has brought to a stop, though not to an end, one of his most remarkable works—those descriptions and figures of Jurassic ammonites, normally from English localities, which began in December 1909 under the title " Yorkshire Type Ammonites " and continued after the War as " Type Ammonites " To how many volumes the series might have extended it is impossible to calculate, so embarrassingly rich is the Jurassic ammonite fauna, and so keen was the discrimination of the author Actually the seventh volume was in progress, and it is now completed by a double part, for which sincere thanks are due to Prof A Morley Davies and his coadjutors, Dr Spath, Dr Trueman, and also Mr Tutcher, who has all along been mainly responsible for the excellent photographs They have performed a laborious task as a memorial to one who throughout his life was a single hearted student of Nature

Both format and form of the work were suggested by *Palaeontologia Universalis*, of which it was originally intended to form part In that work, produced by D P Oehlert and a committee of the International Geological Congress, the essential features were to be a plate referring to each species and bearing a photograph of the type specimen and a reproduction of the original figure, with an accompanying page reprinting the original description and adding such brief notes as might seem necessary Buckman, turning to the type specimens of Young & Bird and Simpson in the Whitby Museum, soon found that more information and discussion were necessary, and rightly judged it more convenient to issue his plates as an independent series As the work progressed, changes were introduced in the method of de scription, important discussions and occasional excursus found their way into the text, new material involved corrections, and, in short, neither the simplicity nor the original plan could be maintained

Prof Morley Davies, therefore, to bring the work to a decent cessation, has here provided a guide to its 1051 plates and its 797 species He has arranged the names of the latter in the order of stratigraphical succession, under hemeræ, and he suggests that the plates might be arranged in a like order, and divided into six volumes The letterpress, with five portraits, would form a seventh volume This list is followed by a list of the plates in numerical order with references to the hemeræ

Then follow an alphabetical list of the 407 genera, with references to plate, page, and horizon, an alphabetic list of trivial names, with references to genus, plate, and hemera, a list of names altered during publication, which, the cynics may be

surprised to learn, amount to only 4 6 per cent, a list of new names appearing first in the text, and an index to ages and hemeræ These and many other notes will make this part indispensable to every user of the work, and subscribers should apply for it without delay

Fresh-water Biology

Life in Inland Waters with Especial Reference to Animals By Kathleen E Carpenter (Text Books of Animal Biology) Pp xviii + 267 + 12 plates (London Sidgwick and Jackson, Ltd, 1928) 12s net

AN introductory work on modern aims and methods in the study of fresh-water life was much wanted, and this book is exactly fitted for the purpose It forms one of the well-known and useful series of Text-Books of Animal Biology edited by Prof Julian S Huxley, who contributes an introduction to this volume The chief object set before the worker is to study the life in inland waters by finding out all that there is to know, not only about the animals themselves and their inter relations with other animals and with plants, but also all that there is to be known about the waters which they inhabit, their physical and chemical nature, geological features, past and present, and how they affect the organisms — in fact, to study the animal thoroughly in relation to its environment

It is often said that life in fresh water has been neglected because of the more attractive life on the sea-shore which is nowadays accessible to almost everyone, but a large amount of excellent and important work has accumulated recently in connexion with fresh water biology, and there is a good foundation laid for research in many fields It is no longer considered sufficient to identify the animals one finds, one must know everything of the life as a whole in each individual area Dr Carpenter is a good field zoologist and her own work has led her to study her subject in this way, therefore she is able to show what is wanted She has produced a real natural history book, attractive and interesting, which will be of much use to all students, supplementing the ordinary text books and courses of study Much that is brought together here can be found only by diligent search in the papers of specialists The bibliographies placed at the end of each chapter are well chosen and contain most of the more important works to be consulted

Perhaps the best parts of the book are the chapters dealing with the biology of streams, rivers, and lakes Here the author is completely at home and the descriptions of the relations and reactions in all groups to so many different habitats make a most interesting whole Fresh water animals are peculiar in offering an enormous number of examples in adaptation, having to withstand numerous and various vicissitudes such as drought, torrents, and differences in physical and chemical constitution of the water in which they live Hence there are hard coated eggs surviving after the death of the parent to burst out into life when better seasons come, or special adaptations for lying dormant either in winter or in summer, special ways of living in rushing streams by clinging tightly to rocks and stones and wonderfully devised apparatus for hanging to the surface film It is peculiarly with insects that such adaptations are at their height and the entomologist has much work before him In spite of all the splendid pioneer work of the older naturalists, whose work still stands as the model of what such work should be, the present-day naturalist has not far to go to find a suitable problem for research He has only to inspect the nearest piece of water, however small, and he will probably find in it some insect the life history of which is unknown A complete survey of the tiniest pond in all its aspects throughout a year can easily occupy many years of work

Apart from the discussions on the dependence of animals on plants as food, the description of the plant life is purposely reduced to a minimum A few plants are, however, mentioned, particularly those in the plankton We should like to know what the author understands by a Peridinian The terms Peridinians and Dinoflagellates are usually regarded as synonymous, but on p 32 we read "Dinoflagellates and Peridinians", and again on p 203, "*Ceratium hirundinella* gives place to and Peridinians", although on p 197 *Ceratium*, *Glenodinium*, and *Peridinium* are given as Dinoflagellates

The last chapter treats of the biology of inland waters in relation to human life, and includes discussions on river pollution, a subject in which the author has herself done good work and which is of ever-growing importance

The illustrations are good, consisting of photographs and clear diagrammatic drawings, the latter perhaps suffering slightly from the roughness of the paper on which they are reproduced This book is recommended heartily to all interested in the biology of inland waters

Our Bookshelf

The Psychological Register Edited by Carl Murchison, in co operation with F C Bartlett, Stefan Blachowski, Karl Buhler, Sante De Sanctis, Thorleif G Hegge, Matataro Matsumoto, Henri Piéron, A L Schniermann (The International University Series in Psychology) Pp ix + 580 (Worcester, Mass Clark University Press, London Oxford University Press, 1929) 27s net

THE difficulties in compiling a "Who's Who" of any kind are twofold first, to decide who shall be included, and secondly, to obtain accurate entries The second difficulty is overcome to a large extent by obtaining particulars directly from the individuals concerned, but, as Prof Murchison remarks in his preface, it is not easy to surmount the language obstacle in dealing with a work which has to cover the whole world The first difficulty, however, is more serious In the volume before us, all full members, and also all associate members with Ph D degrees, of the American Psychological Association, which has high technical requirements for admission, are included For other countries Prof Murchison has had to depend on the nominations of the members of his editorial board, thus Dr F C Bartlett has acted for the British Empire, Dr H Piéron for Latin countries outside Italy, and Dr Z Y Kuo and Dr E Shen have furnished Chinese names

The result of this method of selection—and it is not easy to see how it could have been improved—is that the American entries occupy 296 pages of the book This is, perhaps, not so disproportionate as may seem when the volume of work on psychology carried out in the United States is considered However, the editor is of opinion that other countries are not adequately represented, partly on account of the fact that workers in psychology are often 'labelled' as physiologists, psychiatrists, philosophers, and educationists, and he appeals for additional names in order to make the book truly international in scope

The details given include name, address, date of birth, education and career, and titles of papers (with bibliographies) and published works The entries are arranged alphabetically under countries and there is a name index

Algebraic Geometry and Theta Functions By Prof Arthur B Coble (American Mathematical Society Colloquium Publications, Vol 10) Pp vii + 282 (New York American Mathematical Society, Cambridge Bowes and Bowes, Berlin Hirschwaldsche Buchhandlung, 1929) 3 dollars

IN discussing algebraic curves and surfaces we have the choice of several distinct methods Some authors rely upon Cremona transformations, by which the curve or surface is brought into correspondence with another and simpler curve or surface Others rely upon invariant theory, reducing the geometry to algebra A third school uses parametric representation It is well known how easily the properties of conics are derived by expressing the co ordinates of their points as rational or trigonometrical functions of a parameter For certain cubics, we use elliptic (that is, doubly-periodic) functions When we come to curves of higher orders we need theta functions, which are multiply periodic Some complications arise from the fact that such functions necessarily involve more than one parameter, and are connected by a large number of complicated equations

The special merit of Prof Coble's treatment is that he brings all these various methods into relationship with one another In particular he correlates his own researches, developed by means of Cremona transformations, with those of Schottky, who uses the theta functions as a starting point There are also references to apolarity and a few of the simplest ideas of the theory of groups No thorough treatment of advanced algebraic geometry can be easy reading, but Prof Coble has done as much as possible to smooth our path

H T H P

Dipolmoment und chemische Struktur Herausgegeben von Prof Dr P Debye (Leipziger Vortrage, 1929) Pp vii + 134 (Leipzig S Hirzel, 1929) 9 gold marks

REVIEWS have recently appeared in these columns (NATURE, Jan 4, p 9) of Prof Debye's book on polar molecules, and of a translation of this work into German, which has the additional merit of including an up to date list of values of this important constant The present volume deals with the same topic, and has been compiled under the inspiration of the same author, but it has taken a different form, since it includes within its covers thirteen contributions by nine authors in reference to dipole moment and chemical structure One of the contributions (from an American worker in Brussels) is in English, the remainder are in German, but include papers from laboratories in Zurich and Copenhagen, as well as Hamburg, Wurzburg, Freiburg, Karlsruhe, and Leipzig The volume will be read with interest by those who are in a position to make use of one of the most important methods of deducing the structure of molecules from their physical properties

Vorgeschichtliches Leben in den Alpen Von Leonhard Franz Pp 95 + 23 Tafeln (Wien Anton Schroll und Co, 1929) 6s

THIS book, the author explains, has been written for lovers of antiquity and lovers of the Alps It is a popularly written account of the prehistory of Switzerland from the earliest times of which traces have been found—"Die Zeit der Barenjager", as the author puts it—down to the end of the iron age While it is intended primarily to interest the visitor to the country in its prehistoric antiquities, it will be found a convenient summary of information scattered in various publications The lake villages naturally are treated in some detail The book is illustrated by 82 well selected photographs and drawings

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

The Radcliffe Observatory

I HAVE been requested by the National Committee for Astronomy to forward the accompanying copy of a resolution adopted *nem con* by the Committee at a meeting held on May 9

" In view of the large number of astronomical observatories already existing in the northern hemisphere in indifferent climates, where many important types of observational work cannot usefully be attempted ,

" And in view of the great need for comprehensive investigations in the southern hemisphere with powerful equipment ,

" And in view of the stations in the southern hemisphere already erected, or in course of erection, by several foreign observatories ,

" And fearing the danger of British observational astronomy permanently losing its position in the front rank unless greater use is made of the best climates in the British Empire ,

" The National Committee for Astronomy is of opinion that the establishment in South Africa, under English control, of a new observatory equipped with a large reflector, and adequately endowed, would not only be in the best interests of astronomy, but is almost an imperative necessity in the interests of British scientific prestige

" Such an observatory, if established, would be able to carry out work in the southern hemisphere complementary to that of the Dominion Astrophysical Observatory in British Columbia, which has so signally justified its erection

" Further, the Committee, being aware of the proposed transfer of the Radcliffe Observatory from its present site, is strongly of the opinion that the opportunity should be taken to move the observatory to South Africa rather than to another site in England, and that such a project would be an enterprise of national importance

" The Committee feels confident that if this scheme were adopted, not only would new fields be opened up, but existing facilities would be greatly improved, in particular by co operation between the Oxford University Observatory and the Radcliffe Observatory , and that this co operation would be of much greater value to the study of astronomy in Oxford if the Radcliffe Observatory were transferred to a site in South Africa than if it remained in England "

Of the seventeen members of the Committee who were present when the vote was taken, the following voted in favour of the resolution

A Fowler (Chairman), Yarrow research professor of the Royal Society and professor of astrophysics in the University of London (Imperial College), A C D Crommelin, president of the Royal Astronomical Society , C R Davidson, Royal Observatory, Greenwich , Sir Frank Dyson, Astronomer Royal , A S Eddington, Plumian professor of astronomy, University of Cambridge , J Evershed, lately director, Kodaikanal and Madras Observatories , J Jackson, chief assistant, Royal Observatory, Greenwich, H Knox Shaw, director of the Radcliffe Observatory, Oxford , W J S Lockyer, director of the Norman Lockyer Observatory, Sidmouth , E A Milne, professor of mathematics, University of Oxford , H F Newall, lately professor of astrophysics and director of the Solar Physics Observatory, University of Cambridge , Rev T E R Phillips, lately president of the Royal Astronomical Society , Lord Rayleigh, emeritus professor of physics, Imperial College of Science and Technology , R A Sampson, Astronomer Royal for Scotland , F J M Stratton, professor of astrophysics and director of the Solar Physics Observatory, University of Cambridge , H H Turner, Savilian professor of astronomy, University of Oxford

Quantitative Analysis by X-Rays

IN their interesting letter to NATURE of April 5, p 524, Prof T H Laby and Mr C E Eddy agree with many of the statements in my address to the British Association, but dissent in some respects from my conclusions According to their view, I was not sufficiently generous in stating the sensitiveness of the method The sensitiveness depends on numerous factors such as the energy applied, the time of exposure, the wave lengths to be photographed, and so on, and in a very high degree on the constitution of the sample , traces of copper present in aluminium will give an X ray line incomparably stronger than when present in the same atomic concentration in lead The state of aggregation of the sample is also of great importance , an alloy available in comparatively large amounts, which can be soldered massively on to the anticathode, and, on account of its high heat and electrical conductivity, can be bombarded very intensively by cathode rays, is much better than a sample of mineral possibly available in minute quantity only, which must be rubbed as a powder into the anticathode

As the sensitiveness is to a high degree dependent on the conditions mentioned, no exact figure covering all cases can be quoted , the determination of an element present to the extent of 1 in 10,000 is possible in many cases, and in some special ones lower concentrations still can be determined Prof Laby and Mr Eddy achieved much greater sensitiveness in their analyses than this, and they are to be congratulated on the excellent results they obtained in the analysis of copper or iron in zinc I must, however, entirely disagree with their statement that the entire X ray spectrum of an element can be obtained even at concentrations less than 0 0001 per cent If they try to determine traces of sodium in lead they will certainly encounter very great difficulties even at so high a concentration as 1 in 10,000, and if they try to analyse most mineral samples, they will scarcely be able to attain the accuracy claimed

As the intensity of an X ray line is closely dependent on the constitution of the sample, it cannot be considered an exact measure of the amount of the element present , but if a suitable reference substance be added to the sample and the assumption made that the line emitted by the latter is influenced by the presence of different elements in exactly the same way as the line of the element to be determined, then a comparison of the intensities of the two lines can be employed as a method of quantitative analysis It is only necessary to know the amount of the reference substance added and the intensity ratio of the two lines emitted by equal numbers of atoms of the two elements, which can be empirically determined

While it is convenient to compare lines of equal intensity, partly because a microphotometer is then no longer essential and partly because some of the

disturbing effects are minimised, the method is in no way restricted to these cases In some very special cases an addition of reference substance is not necessary as it is already contained in the sample to be investigated and such special cases were investigated by Prof Laby and Mr Eddy, but this method is of very restricted application and will fail in the whole domain of mineral analysis, and also in many cases of the analysis of alloys The chief field of quantitative X ray spectroscopy, however, is not those alloys which can easily be analysed by chemical methods, but the large domain of mineral analysis where the tedious processes used to dissolve the mineral can be avoided and the great difficulties with elements like niobium, tantalum, and the rare earths, and so on, can be circumvented So far as alloys are concerned, cases like the determination of traces of tungsten in steel or of iridium in platinum might be included

The success of the analysis depends greatly on the suitable choice of the reference substance As mentioned above, we have to assume that the line emitted by the reference substance is influenced in exactly the same way by other constituents of the sample as the line to be investigated If the reference substance is not chosen accordingly, this condition is far from being fulfilled When determining chromium ($K\alpha_1$ 2285 X U) the praseodymium $L\beta_1$ line (2254 X U) is a suitable reference line, but should comparatively large amounts of vanadium be present, the analysis will give a wrong result, as the absorption edge of vanadium (2265 X U) is situated between the two above mentioned wave lengths and as only praseodymium can excite the *K* spectrum of vanadium, a selective weakening of the praseodymium line will take place It was found that the presence of 4 atoms of vanadium to each atom of praseodymium alters the intensity ratio by 63 per cent

When nickel is compared with cobalt in the presence of a large excess of copper, the intensity ratio of the nickel and cobalt lines will be shifted in favour of the cobalt line, as only the cobalt edge can be excited by the copper lines We have here a case of another group of disturbing effects, namely, where strong emission lines of elements present in large amounts are situated between the absorption edge of the element to be determined and the absorption edge of the reference line In a paper in print for the *Zeitschrift für Physik*, a complete list of reference substances is given for all elements between sodium and uranium and the limitations in each case

Apart from the disturbances mentioned above, an entirely different kind of disturbance can originate from the fact that under the influence of the cathode rays a change in the composition of the mixture takes place When investigating a mixture of refractory oxides these disturbances are scarcely noticed Nor have such been noticed by Prof Laby and Mr. Eddy when analysing alloys—their alloys being soldered to the anticathode and having high conductivity for heat and electricity, this can easily be understood But when analysing minerals or chemical compounds, especially those containing components of fairly high vapour tension, very appreciable errors can be introduced To avoid these errors (which were first systematically investigated by Coster and Nishina, and whose work was corroborated and extended by Glocker and Schreiber), it is advisable in such cases to abandon the excitation of the X ray spectra by cathode rays and to excite them instead by X rays and investigate the secondary X ray spectrum

While in special cases such as the one so successfully investigated by Prof Laby and Mr Eddy, methods can be developed where the addition of a reference substance can be dispensed with, only those in which an added reference substance is employed can claim general applicability

Fine Structure of *K* Absorption Limit of Silicon Oxide

THAT the X ray absorption limits are not simple but show a rather complicated structure has been known now for some time The main difficulties in their experimental investigation are in respect of (1) amount of the absorbing substance, and (2) dispersion of the spectrograph The amount of the absorber must not be either too great or too small, otherwise the details are lost Secondly, the dispersion must be made as large as possible to bring out all the details and measure them with the usual accuracy

Fricke investigated *K* absorption limits of some of the lighter elements (*Phys Rev*, **16**, 1920) He could not get any absorption limit at all for silicon This was probably due to his using very thick absorbing screens coupled with the low dispersion which he obtained with sugar crystal Later Lindh (*Zeit für Phys*, **31**, 1925) succeeded in obtaining the *K* absorption limit for silicon both pure and in chemical combination, but no fine structure was seen in any case

Recently in this laboratory I made an attempt to obtain fine structure of the *K* absorption limit for silicon oxide without the use of an extra absorbing screen, the analysing quartz crystal itself acting as the absorber This was done at the suggestion of Prof Siegbahn, to whom I am highly indebted for it The vacuum spectrograph used was one of the latest models of Prof Siegbahn's design made in the laboratory workshop The continuous radiation was obtained with tungsten as the anticathode material The tension at which the X ray tube was worked was kept suitably low and the current density was pushed up as much as possible The rather long exposures of twenty to twenty four hours were amply

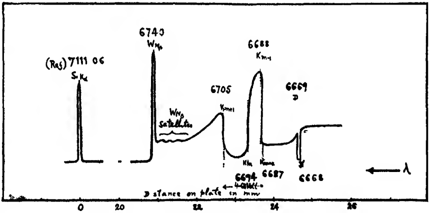

FIG 1

repaid by the extended fine structure of the K-limit of quartz recorded on the plate The blackening of the photographic plate is shown diagrammatically in Fig 1, which also gives the wave lengths in X U of the several edges

It is interesting to note that the white line between D and D' is only 0 054 mm wide, while the width of the slit was 0 091 mm Still farther to the right of DD' there are two more such lines As, however, owing to feeble intensity, their measurement is uncertain, they are not shown in the diagram From the nature of these lines it appears that they are not components of the K-absorption of silicon oxide an explanation of them must be sought in the geometry of the atomic planes of the quartz crystal The discontinuity at DD' recorded on the photographic plate arises, as Fig 2 shows, in the process of division of the incident energy I corresponding to wave-length λ into two parts, one, I_a, regularly reflected towards the photographic plate by a system of atomic planes A (l, m, n), and the other, I_t, simultaneously reflected inwards by another system of atomic planes B (l', m', n') Similar light lines having the appearance of absorption lines were observed with rock salt by Wagner (*Phys Zeit*, **21**, p 632, 1921), O Overn (*Phys Rev*, **16**, 1920, and **18**, 1921) and later on by Berg (*Naturwiss*, **14**, 1926), who extended the observations to other cubic crystals Their origin was explained on the lines indicated above

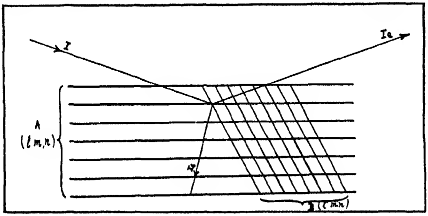

FIG 2

Finally, it may be mentioned that the value of the K absorption edge for silicon oxide as given by Lindh is 6707 5 X U, but the edge was not much separated from the rather intense tungsten $M\beta$ line registered on his plates

A detailed account of the above will be published elsewhere G B DEODHAR

The Parachor and Molecular Volume

DR FERGUSON's letter in NATURE of April 19 is a little difficult to follow At first he agrees with me that the parachor is a comparative measure of molecular volume "at temperatures such that the surface tensions are equal", yet later he says emphatically that "it is certain that the parachor is not a molecular volume"

It is evident that the term "molecular volume" must here be used in two different senses The most direct significance of this expression is the actual volume of N molecules (where N is Avogadro's number) Our knowledge of the dimensions of molecules is, however, very limited and is mainly based on collision areas deduced from gas viscosities, to convert these into volumes involves hypotheses concerning the shape of the molecule and thus introduces large uncertainties From the time of Kopp it has been assumed, implicitly, or explicitly, by many writers that the volume *occupied* by a gram molecule of the substance in the liquid or solid state under some standard condition is a measure of the volume of the molecule Comparisons of such molecular volumes have been made for the volumes occupied at absolute zero, at 0° C, at the boiling point, and at the critical temperature, hence when I used Macleod's equation to calculate the volumes occupied by liquids at constant surface tension I did not (and still do not) consider it unjustifiable to regard the result as a measure of molecular volume

The relation between the parachor and the critical volume was never put forward as an accurate physical law but as a rough test of the view expressed above Dr Ferguson's relation is undoubtedly more accurate, it is interesting to note, however, that as the complexity of the molecule increases, V_c and θ_c increase together in such a way that the ratio $V_c^{1/6}/\theta_c^{1/4}$ involving small fractional powers of these quantities is nearly constant Hence except for hydrogen and helium both my relation and Dr Ferguson's hold with fair accuracy I am indebted to Dr Ferguson for correcting my blunder with regard to the critical volume of hydrogen, both this gas and helium give a ratio of P/V_c which is much smaller than that given by most other substances

I gather from Dr Ferguson's letter that he considers the critical volume to be the most significant of all the molecular volume constants I have endeavoured to test this point by a comparison of molecular diameters deduced from gas viscosities with those calculated from parachors and from critical volumes (*Jour Chem Soc*, 1055, 1929) Spherical molecules and close packing are assumed and these hypotheses lead to considerable uncertainties The following data are taken from this paper σ_c and σ_p represent the diameter of the sphere occupied by the molecule at the critical temperature and at unit surface tension (parachor) The ratios of these quantities to σ_η, the molecular diameter obtained from viscosity measurements, are given in the last two columns

Substance	σ_η	σ_p	σ_c	σ_p/σ_η	σ_c/σ_η
Hydrogen	2 18	4 34	5 33	1 99	2 44
Helium	1 94	3 61	5 12	1 86	2 64
Neon	2 32	3 88	4 60	1 67	1 98
Argon	2 90	5 01	5 73	1 73	1 97
Chlorine	2 18	6 38	6 61	1 55	1 60
Bromine	4 12	6 75	6 81	1 67	1 69
Hydrogen chloride	4 04	5 41	5 93	1 85	2 02
Benzene	4 20	7 84	8 42	1 87	2 01
Propyl Acetate	4 67	8 42	9 31	1 80	1 99

It will be seen that the critical volumes of helium and hydrogen give abnormally high values for the ratio σ_c/σ_η, whilst the ratio σ_p/σ_η based on the parachor for these substances is more nearly in agreement with

that found for more complex molecules This may be due to the unusually large forces between the molecules of hydrogen and helium due to the presence of two electrons only in the outer shell, in most other substances the outer shell of each atom contains eight electrons and the intermolecular forces are correspondingly modified Hence the parachor, in which some attempt is made to allow for the effect of internal pressure on the volume occupied by a gram molecule of a liquid gives a rather better parallelism with the viscosity data than does the critical volume The uncertainties involved in the data and in the hypotheses used in the calculation of diameters are large and must be borne in mind when attempting to interpret the ratios given in the last column of the table The abnormality of the critical volumes of hydrogen and helium is, however, so great that I think it must be regarded as real

A Method of obtaining Stages in the Life-history of the Liver Fluke for Class Purposes

THE life history of the liver fluke (*Fasciola hepatica*) was described by A P Thomas in *Q J M S*, Lond, vol 23, N S, 1883 He succeeded in rearing experimentally the early stages of the complicated life history of this parasite by collecting eggs from the gall bladder of sheep bringing about their hatching under suitable conditions, and infecting the molluscan host, *Limnæus truncatulus*, from which he obtained both rediæ and cercariæ, using the latter for the infection of young lambs His methods, however, are not suitable for class demonstration owing to the difficulty nowadays of getting the eggs of the fluke from heavily infected sheep

During the past two years I have used a simpler method It is generally possible to obtain from the local abattoir a few specimens of adult flukes either alive or dead The flukes should be washed free from bile and mucus Each specimen is then dissected under the Zeiss binocular dissecting microscope and the contents of the uterus emptied into a flat bottomed watch glass Some of the eggs will be yellow in colour and are suitable for hatching experiments, others are white and should be discarded The yellow eggs sink to the bottom of the water, and when a sufficient number have been extracted, the fluke tissues and clouded water are pipetted off Repeated washing leaves the eggs in a clear fluid The development of the eggs can be studied under the microscope from day to day Every few days the water should be changed Warning of the hatching of the eggs is given by the appearance of cilia and of the X-shaped eye spot At first the young embryo squirms up and down within the egg shell, but about the last day before hatching it turns round as if trying to find the exit The period of development varies with the temperature, in spring it is about a month, but is less in warmer weather The eggs hatch in batches in the morning and the larvæ are phototropic By the same evening all are dead unless they have found a host

As soon as possible after hatching, a specimen of *Limnæus truncatulus* is introduced into the dish In a short time it acts as a focus around which the miracidia swarm The actual penetration can be watched under the Zeiss binocular Large numbers of the larvæ fix themselves to the tentacles, head, and mantle of the snail, so that the unfortunate and apparently unconscious mollusc is bristling with white threads, which show up well against its dark skin As many as sixty were counted on one snail, and this does not include those which entered the pulmonary chamber and were lost to view The larvæ bore like screws, and take from fifteen minutes to an hour or more to disappear within the snail

Specimens of *Limnæus* preserved at this period and afterwards sectioned show the miracidia entering the body, while snails killed after an interval of two or three weeks exhibit the sporocyst and redia stages Many of the miracidia do not develop, Thomas says they must enter the pulmonary chamber or body cavity and that they do not develop in the foot I have, however, found them in the kidney, dorsal body wall of the head and sides of the foot Thomas also states that few snails survive three weeks of artificial infection, but I have had no deaths as the result of infection, however heavy Snails were infected this year on Mar 11, and are still alive and active

Parasitism in Relation to Pupation in *Lucilia sericata* Meig

IN NATURE of April 19, p 598, Holdaway and Evans make reference to the stage in which the hibernation of *Lucilia sericata* Meig takes place Their observations show that although "both larvæ and puparia were recovered from the soil surrounding baits exposed in the autumn and examined towards the end of the season", that 87 4 to 92 2 per cent of these puparia (plus larvæ pupated within eight days of collection) were parasitised From these facts it is evident that in Toulouse, France, from which station the letter is addressed, the normal mode of hibernation of *Lucilia sericata, excluding the influence of parasitism*, is in the larval stage, and thus is similar to that found by me in North Wales in 1928-1929 (NATURE, May 18, 1929, vol 123, p 759) In the latter case, and again last winter, when observations on the hibernation of *Lucilia sericata* have been confirmed, not a single puparium appeared among the hibernating larvæ

This fact at first appears striking, since Holdaway and Evans found hibernating puparia which did not yield parasites It should, however, be noted that I was dealing with larvæ obtained direct from living sheep, and not with larvæ from exposed baits as was the case in the work of Holdaway and Evans It proved very significant that from the 5622 larvæ obtained periodically from living sheep during the survey in the summer 1928, and from the many batches of larvæ obtained from similar sources throughout the summer 1929, no parasite was bred This fact no doubt explains the absence of stimulated pupation among the hibernating larvæ, and thus, as negative evidence, supports the observations of Holdaway and Evans that pupation among hibernating larvæ is stimulated by parasitism

Further, the complete absence of puparia among these non parasitised hibernating larvæ upholds the view that in the observations of Holdaway and Evans the puparia present which did not yield parasites had been previously stimulated to pupate by a secretion or other factor operative during the oviposition of the parasite, which oviposition had been non productive

The absence, or the extraordinary rare occurrence, of parasitism among larvæ of *Lucilia sericata* obtained from the living host will, no doubt, prove an important factor in the success of *Alysia manducator* Panz in the biological control of blow flies The living sheep will obviously be a constant and important source of unparasitised larvæ The reason for this immunity cannot be the absence of the parasite from the

localities from which the larvæ were obtained for specimens of *Alysia manducator* have been observed in quantity near carrion in several districts in North Wales On the other hand, it is well known that the primary attraction of this parasite is the chemotropic action of carrion, hence it would appear that a live sheep attacked by larvæ of *Lucilia sericata* offers no attraction for ovipositing females of *Alysia manducator*, and thus the larvæ in this environment escape the attacks of the parasite

Coloured Glass as a Deterrent to House Flies

LAST autumn we received an inquiry from Mr L Macqueen Douglas, of Newpark, Mid Calder, Midlothian, who asked us whether we had any data concerning the action of coloured glass on house flies In his experience coloured class, especially blue, acted as a deterrent, and he was using it in the construction of abattoirs, etc At that time we were unable to obtain any further information upon the subject On the appearance in NATURE of April 5 of the letter from Messrs Pilkington Bros , who stated that red and yellow are the best deterrents and that blue and green are not nearly so effective, I communicated these facts to Mr Douglas He replied stating that he had carried his experiments somewhat further, and that from his experience blue glass is to be preferred to yellow for two reasons First, he found that the blue glass was completely effective in preventing the development of flies , and secondly, that the blue glass does not give an offensive look to the meat, while yellow glass gives it an unhealthy looking colour which from a commercial point of view is highly objectionable

I might add that Mr Douglas's experience of abattoirs and their construction is very extensive

A D BUCHANAN SMITH

King's Buildings,
West Mains Road,
University of Edinburgh, May 1

MESSRS PILKINGTON BROS , in NATURE of April 5, raise an interesting point regarding house flies and their dislike of light of certain hues The following observations, made during September of last year, may be of interest

Two similar small rooms were roof glazed, one with ordinary rolled plate, the other with a proprietary heat absorbing glass transmitting bluish green light Ventilators in the two rooms gave insects equal opportunities for ingress, but at the end of a fortnight the numbers of insects in the rooms were so obviously unequal that a count was made, with the following result

Type of Insect	Under Clear Glass	Under Bluish Green Glass
Flies	19	8
Moths	4	1
Wasps	4	0
Spiders	3	0

It should be added that, during hot weather, the maximum air temperature in the room glazed with rolled-plate was usually 5° or 6° F greater than that in the other room There was also a marked deficiency of infra-red radiation beneath the bluish green glass which may partly account for the results obtained

Nutritive Value of Elm Tree Bark

IN the water meadows opposite my home in Chalfont St Peter several elm trees were blown down by last winter's gales The horses and cows grazing on these meadows spent much of their time in chewing off the bark of the boughs of the fallen trees, although there was abundant young grass growing on the meadows all through the last months of a mild winter

Interested by this fact, I put two lots of seven mice, just weaned from well fed, healthy mothers of known stock, on a diet of white bread and water, and to one lot I gave some elm tree twigs every few days The mice gnawed the bark off the twigs At the end of seven weeks these mice had gained 45 gm , while the control lot had gained only 22 gm in weight X-ray photographs showed no difference in the lines of ossification of the bones in the two lots, so that the bark was not eaten for the sake of vitamin D This might be thought to be deficient in winter grass owing to the low intensity of the short ultra violet rays of the sun The fur of the mice which ate the bark had a sleaker appearance

LEONARD HILL

Ionisation in Nitrogen

EXPERIMENTS on corona discharge in carefully purified nitrogen at low pressures show that the mobility of the negative carriers is much lower than that found for electrons by Townsend and Bailey (*Phil Mag* , December 1921), as is shown by the following table

X/p	ωp	
From 10 to 40	$4\ 4 \times 10^5$	Townsend and Bailey
25	$12\ 9 \times 10^4$	Corona Experiments
20	$9\ 0 \times 10^4$	,,
15	$5\ 7 \times 10^4$	,,

X = electric force in volts per cm
ω = mobility in cm per sec per volt per cm

Since Townsend and Bailey's experiments show that electrons retain their high mobility for a considerable time, the carriers cannot all be electronic The greatest possible proportion of electrons present varies approximately linearly from 0 025 when X_0/p (at the surface of the inner cylinder) is 350 to 0 012 when X_0/p is 200

Oxford, April 23

Undercurrents in the Strait of Gibraltar

IN view of the lively discussion of the undercurrents in the Strait of Gibraltar during recent years, some observations made by H M Surveying Ship *Goldfinch* (Lieut Commander F H Walter) in 1905 with the Pilsbury Current Meter, where I was serving as Senior Assistant Surveyor, may be of interest They were not published, since they were not taken under good conditions, but they are amply sufficient to show that at a position N 53° W (True), 7 miles from Cape Spartel, the current between the surface and 200 fathoms was easterly and weak , below 200 fathoms it began to turn to the west, and observations between 250 and 290 fathoms showed currents of more than 5 knots flowing nearly west True It is hoped that it will be possible to publish the observations in full, shortly

Josiah Wedgwood and his Influence on the English Pottery Industry

By S R HIND

IN order to understand the state of the pottery industry of Britain at the time Wedgwood took up his labours, it is necessary to go back to a period some forty years before his birth in 1730 At this time the products of the Staffordshire potteries consisted of heavy, coarse ware made of local clays in the form of platters, drinking and cooking pots, butter pots, and similar articles These were crudely made, usually on the potter's wheel, ornamented in an elementary way, if at all, and glazed imperfectly by means of raw lead preparations such as galena

One great exception, indicative of the change to come, must be made on behalf of the secret manufactory of the brothers Elers, natives of Nuremberg, who had come over from Amsterdam and developed a new kind of ware at Bradwell Wood, near Burslem They manufactured a fine red stone ware out of carefully prepared local clay, the articles being lathe turned whilst partially dry, ornamented with applied designs of sharp outline, and finally salt glazed These new methods ultimately became diffused in the neighbourhood, with some loss in effect for the time being, but an enormous stimulus to progress, by the efforts of the elder Astbury

Astbury's use of washes of finer clays marked the beginning of a line of development which led to various forms of ornamentation, engobes, and glazes of composite and infinitely superior character The uses of various lead compounds, feldspar, borax, and other glaze components began to be explored and their qualities modified by a preliminary fusion or fritting

The advantages of flint in admixture with both bodies and glazes soon came into prominence Its preparation by dry grinding, following calcination, led to many cases of what we know now as silicosis, this danger was reduced very markedly by a painter named Benson, who introduced the wet grinding process Later improvements in the application of water and wind power and the use of mill runners of chert, a fairly pure form of silica, in place of granite, take us down to the early careers of Brindley and Wedgwood

Other notable advances were in connexion with plaster of Paris moulds, the use of the red clay colour trials of Thomas and John Wedgwood in controlling the firing of ovens, an increasing appreciation and importation of ball clay and pipe-clay from the south of England, the use of the slip kiln, and the introduction of biscuit firing (that is, separate firing of the body before application of the glaze) by Enoch Wood, this at a time when Wedgwood had already launched out in his early partnership with Harrison and Alders

By this time, a coarse cream earthenware, white or greyish-white and red stoneware and tortoiseshell ware, were the staple of the district The field was set for great advances, but the master-hand was lacking, and trade was even declining, owing to the competition of Delft or Dutch enamelled pottery, which was being imported in large quantities in 1759, the year in which Wedgwood commenced operations as a master potter

So much, as the briefest of summaries, must serve as an indication of the outward circumstances in which Josiah Wedgwood commenced his great work A few details as to his early life will serve as a slight guide to his reaction to these conditions Born the thirteenth child of a master potter in modest circumstances in Burslem, he received such education as could be obtained in the local schools This, however, only lasted until his tenth year, when his father died and he was put to work as a potter under his eldest brother Thomas He appears to have had the instincts of an artist and a craftsman even at this early age, and became a proficient thrower A violent interruption in the form of an attack of virulent smallpox laid him low after two years and this left after-effects, notably a weakness in the right knee, which ultimately led to the amputation of his leg Returning to work, he soon found that he could not continue 'throwing,' and had to turn his mind to other branches of the work The variety thus enforced, coupled with the suffering and meditation incident on his illness and its after effects, must have assisted the godly discipline of his mother in developing a noble and imaginative character, whose great and indeed sole objective was to excel in his craft

Wedgwood's mind having a strong experimental bent, and his brother having no desire to widen the scope of his manufactures, Josiah at the close of his apprenticeship threw in his lot with Harrison and Alders, owners of a small pottery, and later with a more progressive potter named Whieldon of Fenton Low Even this period was not uninterrupted by illness, which only appears to have tempered the true steel of the young potter, and left his energies unabated By now (1759) he had studied every branch of the manufacture of ordinary pottery and even its sale, being impatient of further restriction, he commenced business at the Ivy House, Burslem, having engaged a second cousin, Thomas Wedgwood Thomas had previously been a potter at Worcester and afterwards became his cousin's partner in the manufacture of 'useful' ware, chiefly the improved cream ware. The business grew rapidly, potters were trained to the improved methods, and by 1763 the need for increased accommodation had become so pressing that Wedgwood took over the Brick House Works (Bell House), Burslem His close application to every detail of manufacture, improvements resulting from constant experiment and subdivision of labour, resulted in what, in those days, was nothing less than mass production

Having established his manufacturing unit on sound lines, Wedgwood now turned more and more of his attention to organising his connexion with

the outside world An illness due to a further injury to his leg on the way to Liverpool led to a long stay in that town and a friendship with Thomas Bentley, out of which developed a partnership which relieved Wedgwood of a great part of the exploitation of his wares Bentley gradually transformed his business from that of a general merchant and exporter to that of pottery merchant solely Wedgwood and Bentley ultimately went into partnership in ornamental wares The latter transferred to London and supervised the sales of Wedgwood ware in the Court circle, also managing an extensive decorating works in London He secured artistic and other services and was a constant friend and adviser to his partner on almost every phase of the joint enterprise

At this period Wedgwood entered into arrangements with Sadler and Green of Liverpool, with respect to the printing of outlines of on glaze decoration according to the transfer method de vised by Sadler These outlines were afterwards filled in by hand The method was later extended to include the whole decoration Sadler and Green also possessed enamel kilns of their own for fixing such decoration, and did a thriving trade by buying ware, particularly from the Liverpool potteries, decorating it and reselling

By the time these developments had taken place, Wedgwood's improved cream ware had become an important article of commerce, restored the export trade of Great Britain in pottery and been accorded Royal patronage, in honour of which it was henceforth known as Queen's ware A further expan sion of accommodation was necessary, resulting in the purchase of a new site, and the erection of what was then a model factory and village at Etruria, near Hanley The Burslem potteries were still retained

Wedgwood had also meanwhile been actively engaged in the improvement of local conditions, notably in taking a prominent part in the develop ment of means of road and canal transport, and he reaped the benefit in the then ideal situation of his new works

A new era of prosperity now opened up The cream ware attained the height of its perfection Exports to every part of Europe and to America continued to grow Catherine II of Russia commissioned the manufacture of a stupendous set of table ware amounting to 952 pieces A large number of these had to be specially modelled, and the plates and dishes were embellished, besides the normal rim decorations, with hundreds of paintings of English castles and mansions Great use was made of the camera lucida in securing these views It is doubtful whether this form of ornamentation can be considered to be in keeping with Wedgwood's excellent and restrained taste in decoration, but as a work of art, largely intended for show purposes, the set was certainly a wonderful achievement A number of pieces corresponding to those of the set were also made for other purposes, but without the frog badge which was ordered as part of the original decoration

Wedgwood's service to English pottery went much further than such improvements in serviceable ware as have been touched upon He saw possibilities in ceramic products, of elevating the whole tone of artistic appreciation in the country and abroad In his jasper body, a unique composition requiring great skill in manufacture, but yielding the finest results, he saw the possibility of reproducing works of art at a cost which would render their wide dissemination a practical proposition Ceramics was to become to the arts as the invention of printing to the sciences Space will not permit of any but the briefest reference to the lines this development took

Excellent books exist to show the success he achieved Wedgwood concentrated on every available source of artistic material, books of drawings from the antique, collections of cameos and gems, and the original works of a large number of artists, amongst whom Flaxman, Hackwood, Webber, and Tassie are pre eminent

The black basalt body had been improved to the point of making it an admirable medium for busts and vases The jasper body, normally translucent and white, a delicate body of which the chief con stituent was cawk or barium sulphate, was controlled as to translucency, the special difficulties encountered in its firing were overcome after lengthy experiments, and blue, green, yellow, lilac, and black bodies were prepared from it by suitable additions of colouring oxides , and their agreement with one another in firing shrinkage ensured

The moulding of cameos, first with plaster moulds, was replaced by the use of the technically more perfect, but more troublesome moulds of fired clayware, and ultimately the finest results in coloured backgrounds were attained by the substitution of coloured washes or engobes for the solid coloured bodies The use of the improved lathe was called in to add fluting, chequer, and other effects The principal uses to which the new combination of materials and technique were put, lay in bas relief ornament on ornamental ware of all descriptions, portrait cameos, medallions, vases, plaques, and panels for fireplaces and cabinet-work The most famous, if not notorious, application lay in white jasper ornaments on the famous cobalt blue ground Perhaps the most beautiful to the modern eye are the few existing examples of low relief classical ornament in white on the white ground Undoubtedly, the most remarkable and difficult examples are the copies of the Portland or Barberini Vase

A few words, even in such an incomplete account as this, must be devoted to Wedgwood's association with the scientific men of his day Throughout his life he maintained as close a contact as possible with the progress of chemical and physical science He was a regular correspondent with Priestley and Darwin (Wedgwood and Darwin were both grandparents of Charles Darwin), and well known to the fraternity of the Royal Society, to which he was elected for his clay shrinkage pyrometer This was developed out of his experiments on controlling the heat in his ovens, and it remained for long unrivalled for the purpose

Josiah Wedgwood made notable contributions

to our knowledge of glazes, colours, decorations, saggars, and in fact practically every department of pottery manufacture It must be admitted that the times and conditions to which he was born conspired together to favour a rapid development of the pottery industry, and that other men of his day, Spode and Turner, for example, also made worthy contributions to that development Nevertheless, it is clear that he was their acknowledged leader and a man of the greatest generosity and natural ability

He died in January 1795 after a life dogged by ill health, but inspired to the last with the creative enthusiasm of his craft

The Importance of Cataclasms in Evolution *

By Dr G P BIDDER

A CATACLASM is the result of an exceptional drought, flood, heat, cold, volcanic disturbance, or change in constituents of atmosphere or ocean, or other change in environment which over a large area is fatal to all species or individuals saving those which are exceptionally provided, quantitatively or qualitatively, so as to survive the ordeal This definition is in strict agreement with Southey's use of the word in 1834 (Oxford Dict) We may consider the essential phenomenon of a cataclasm as the reduction, by some violent happening, of a populous region of earth or sea to sterile emptiness, which is repopulated by the few survivors of the disaster † Destruction may come upon all living beings from a volcano, or from a volcanic wave upon land and freshwater organisms, or from a pandemic disease upon only a single group of animals

Darwin recognised the importance of the cataclasm, but he rarely emphasised it, probably because diluvial doctrines had so long held the field It is now generally overlooked in theoretical discussions The possibility of a given species character or individual variation having survival value is commonly discussed from the point of view only of normal environment, without recognising that eschatological environment has equal or greater importance in the selection of races, and in regard to many characters must have been the only decisive factor

If a small heritable quantitative or qualitative difference can lead to the survival of an individual in a catholic danger which destroys all individuals of the species not endowed with such a difference, then, though the danger recurs but once in 50,000 years, that difference must eventually be stereotyped as a character of the species In the intervening 50,000 years of peace many successful variations may take place which do not include this saving difference, but they are pruned by the next similar cataclasm, the survivors of which will again all conform to type Thus cataclasmic selection may enforce specific characters which are normally useless

The position may be illustrated by considering at length the brief argument on the giraffe's neck in the sixth edition of the "Origin of Species", recalled to notice by Pycraft's interesting essay in *Science Progress* for January last Darwin says "The individuals which were the highest browsers and were able during dearths to reach even an inch or two above the others, will often have been preserved" The value of the passage is that it explains how, in the face of universal death, a very small quantitative advantage may save the individual In normal times a giraffe with a neck two inches longer might gather 1 per cent more leaves than his brother and be perhaps ½ per cent better nourished, and the *advocatus diaboli* is in his rights when he claims that this would have no survival value In the great dearth, when all on the ground is eaten and the trees are stripped up to the full height that the tallest giraffes can reach, all must die of starvation Yet if half a dozen giraffes now come who can reach two inches higher, they will find two inches of untouched leaves on every tree, and they alone may survive, to transmit their slightly longer necks to their progeny after the cataclasm ‡

On these premises, there is little positive advantage to the progeny in having a *long* neck, the advantage in a dearth is in having a *longer* neck than the rest of the population At the next similar cataclasm the survivors would be those with necks two inches longer than the now increased usual maximum of neck, and the survivors of the second cataclasm would transmit necks two increments longer than those of the original population In a dearth, two inches added to the mean or modal length of neck might add, perhaps, a few hours to the duration of dearth required to kill off the herd, but the deviational excess of the length of neck in a single individual may ensure his solitary survival through another month of dearth If this deviational excess be heritable, we have it enforced on the post cataclasmal population as an example of what we may term 'futile' evolution, defining

* Slightly modified from a paper read before the Linnean Society, abstract in *Proc Linn Soc* for Feb 6, 1930

† The word 'cataclysm' has a valuable use in its original technical significance of a widespread submergence of land This was a legitimate application of the English form of the Greek word in Matthew xxiv 38, the Vulgate Latin 'diluvium' having been reserved for the supposed post-Tertiary universal deluge The modern protean use of 'cataclysm threatens to render the word unserviceable

‡ Such transmission will obviously take place to all descendants if the two inch longer neck be a Mendelian recessive mutation, and to 8/9 of the descendants if it be a Mendelian dominant, and the survivors show a typical sample of $2DD+4DR$ Most biologists would agree that there is no transmission if the extra height is merely 'metamplc —due to especially favourable accidents of nutrition and the like But on Galton's famous law of Heredity, which declared that to the total heritage of the offspring the parents on the average contribute 1/2, the grandparents 1/4 ', etc, if we agree with Bateson (1909 'Mendel's Principles of Heredity', p 6) that there was admittedly a statistical accord between Galton's theory and some facts of heredity ' and consider that the facts as to stature in giraffes probably come into this category —then, if all the pre-cataclasmal-ancestry be assumed normal, all the post-cataclasmal progeny would have a mean which deviates from the pre-cataclasmal mean by half the deviation of the survivors through the ordeal

'utile' evolution as that which enables the species to populate an environment where it could not otherwise have lived (Futility in evolution, not cataclasmal, is shown by the useless height of the 'canopy' in forests the trees of which have long been forest-trees, competing each against his neighbour [1] In human affairs, competition between nations has produced alike the evolution of manufacturing machinery, which is utile, and the evolution of battleships, which is futile)

Of the survivors who had been exposed to the Black Death in London many would have been selected for a physiological difference which enabled them to resist a single disease Since many centuries of normal environment had not selected this difference, those who possessed it were probably inferior men in normal environment The death in a war of a disproportionate number of the best of the nation is too widely and bitterly believed to be discussed

The Black Death killed up to half the population, but we are considering especially cataclasms after which not 1 in 1000 is left alive The problem presented itself in connexion with littoral sponges I have maintained the thesis [2] that the evolution of the canal system in sponges can be shown to result in the continuously improved separation of the expelled water, which is foul and deprived of food, from the supply of fresh water taken in the accepted sequence of evolution of the canal system demonstrably resulting in a more forcible jet from the vent, carrying the used water farther away from the sponge

On the rocks of Plymouth Harbour grow in profusion the sponges *Halichondria*, *Grantia*, and *Sycon* Sycon's well known bottle-brush scheme of canals is most easily shown to result in the jet (represented by the handle of the bottle-brush) having enormously more power than its tributary currents, which pour into it radially along the bristles *Halichondria* is the sponge in which Grant discovered sponge-currents he vividly described the extraordinary power of the ejection of water from the volcano like vents of the sponge With *Grantia* I have been able to demonstrate to friends a jet some inches long, several times its own length, even from a rather unhappy sponge

These three sponges live between tide-marks in the surf and the swirl, and the power of their jets is in that environment of absolutely no value to them It is known that they have lived on similar rocks in those parts for a hundred years with a generation every year, and it is reasonably certain that they have so lived for 10,000 years, and probably very much longer It seems certain, on the other hand, that their beautifully perfect canal-system—so admirable adapted to bring them food and oxygen in still water—*must* be essential to them

These apparent contradictions are reconciled if we consider that every now and again—maybe once, maybe a few times in a century—the whole of that littoral between tide-marks may have every sponge on it killed, and perhaps nearly every living thing The most obvious means of death would seem to be if heavy rain, of the rare intensity of an inch in an hour, were to fall on the rocks during the two hours of lowest spring-tide This would certainly not happen nearly once a century, but extreme heat from the sun at low spring-tide is another possible lethal agency, and in that part of the coast low springs are at the time of day when heat is greatest Confining ourselves still to natural causes, a landslip might conceivably poison the water, or mud might, for a tide, cover a long stretch of shore

After such a denudation the sponge population would be replaced by the larvæ from sponges in sheltered submarine caves Of the enormous number of larvæ from the surf-sponges, a few will fix on every surface within a long range The young sponge in a still, shut in, cave will not grow so large or so fast as her sister among the waves, but she can live and grow *because* of her perfect current system, and her larvæ can swim to the light, out of the cave, and repopulate the shore So that for the next century or so, until the next disaster, the rocks will grow thick again with *Sycon*, *Grantia*, and *Halichondria*, which will be all descended from a few ill nourished individuals that at the time of the cataclasm lived in retreats where a powerful canal-system was necessary to life Consequently we find the shore populated by littoral sponges with an elaborate anatomy which is useless for littoral existence

We see, therefore, that cataclasmal selection may enforce a character which (1) may be of no benefit in normal life, (2) may carry, associated with it, characters selected by environment before the cataclasm and transmitted because they were possessed by the only surviving organism, while (3) small quantitative differences may have survival value in a cataclasm We may tentatively consider whether some unsolved zoological problems may not be explained by cataclasmal selection Prof Poulton [3] has suggested the interesting case of the whelks of the Red Crag, which are all sinistral He has considered the probable explanation of this to be that there was a sudden refrigeration, which killed all but one whelk which happened to be sinistral, and that her progeny repopulated the Crag * Great cold, great heat, and floods are the most widely recognised depopulating agencies in our past history it may be permitted, interrogatively rather than assertively, to sketch some possible evolutionary results of the cataclasms such convulsions must have caused

The mass-wanderings of lemmings, and in a less degree of mice, rats, and squirrels, appear explicable if we assume a mutational madness, the possessors of which were the only survivors of their kind from the glaciation of northern Europe, and their descendants the only rodents to spread themselves over northern Europe when free of ice again The most inexplicable feature of the wanderings is the

* In 1882 all the Tile-fish off Nantucket were killed, 5000 to 7500 square miles of sea being covered with dead or dying fish, estimated to number 'one billion' (query, a thousand million ?), fifty being counted in a square rod This was attributed to the temporary lowering of temperature of the water —Lucas, 1889, Report of National Museum, Washington, p 612

lemmings throwing themselves into the sea Darwin's visualisation of the glacial epoch is helpful "The inhabitants of the more temperate regions would at the same time travel southward, unless they were stopped by barriers, in which case they would perish" [4] Therefore the sane lemmings which would not throw themselves into the fjords and rivers perished in the increasing cold Wiman * describes the state of a modern wandering horde as "a sort of madness", may we not conclude that this madness was a mutation which had occurred among the lemmings at the Glacial Epoch? Unafraid, the lunatics plunged into the obstructing lake, and because it was mostly frozen got safely across, and continued their lunatic wanderings over insane distances which brought them into gentler climates where they were able to live and produce young lemmings with lunacy inherited from both parents When the ice had passed these were selected again, because only the lunatics made the return journey, the others stayed south and died as the warmth increased On this hypothesis, therefore, in the pre glacial and again in the post glacial generation every ancestor of the modern northern lemming was possessed with a wandering madness

It is worth considering whether there may not have been crises in our own ancestry through which no man lived who was not possessed with the appropriate madness, and whether this form of cataclasmal selection may not explain some features in human psychology, particularly, perhaps, in the behaviour of a crowd On the other hand, the great drought in the central steppes of Eurasia, which drove our ancestors to migrate with their herds over thousands of miles of wolf-hunted plains, may account for the difference in ability for sustained concerted action between the descendants of the stationary Mediterranean races and those of the migrants †

The 'ordeal by fire' is one which must have left its mark in countries where forest-fires or prairie-fires are common, and where, therefore, during the ages, from time to time a succession of wind-changes will have extended the conflagration until the whole great forest was burned J Weigelt [5] says that one of the chief causes of mortality among larger animals escaping a fire is their being crushed to death by fellow-animals in the stampede Is it possible that the extraordinary lateral spread of the horns of some buffaloes and oxen has enabled their ancestors in such a crisis to survive those of the herd whose horns curved upward or forward?

* Quoted by Weigelt

† An observer of lemmings of considerable authority objected at the meeting of the Linnean Society, that lemmings make no considerable migrations or traverses of water, but only scatter from infected burrows under the influence of a known bacterial disease which renders them irresistibly thirsty Another, an authority on rodents, accepted this, and denied the mass-migration of rats or mice These two authorities are in conflict with the observers quoted by Johannes Weigelt ("Rezente Wirbeltierleichen, 1927, Leipzig, Max Weg, p 43) B Högbom observed a dense horde of swimming lemmings 2 to 3 kilometres long near Tromsö, Wiman travelled through such a swimming horde for an hour, and A Högbom observed a closely packed procession of some sort of field mouse (all quoted from *Paläont Zeitschr*, 1913, Berlin, Bd. 1, p 147) Waterton was convinced that "rats move from place to place in large bodies" ("Natural History Essays" [1880], London, Frederick Warne, p 241), but he only quotes one witness Lyddekker (*Enc Brit*, 1910–11, "Lemming") bases on Collett a circumstantial description of mass-migrations of the lemmings lasting one to three years, and writes that they are "impelled by the restless or migratory instinct possessed in "a less developed degree by so many of their congeners"

I am told that in Australia the first sign of a fire in the forest is the escape of the winged things—birds and insects This gives another reason for delicate olfactory organs in insects, equally cogent with sex or food

In Australia every tree and bush is burned, and nothing remains but hot ashes—through which the seedling eucalypti rise to refill the long swath in the forest But in Siam and India the old teak-trees stand, and in Honduras the mahogany trees, and Pinchot [6] says that in the United States, "Trees whose thick bark or abundant seeding gives them peculiar powers of resistance, frequently owe their exclusive possession of vast areas purely to the action of fire" In such resistant trees bees nests might be unburned even if all the bees were killed by the smoke Is it conceivable that the use of wax for the cells by social bees, instead of salival cement, has had the survival advantage of protecting the pupæ from the poisonous vapours of the forest fire which suffocate the adults of the hive?

Is it possible that the high development of the spleen, which can now save the life of a man after moderate poisoning by carbon monoxide, may have been forced upon mammals by forest and prairie fires? It must be remembered that for selective efficiency these disasters need not be frequent if they are terribly mortal

Dr G S Carter has recently explained [7] his interesting theory that fishes took to breathing air because of the lack of oxygen in tropical swamp-water I am not aware whether the descendants of any freshwater fish in the Carboniferous epoch were represented as freshwater fish in the Tertiary rocks *A priori* it would seem possible that with the enormous extent of stagnant tropical swamps at the time of the coal measures, all their aquatic inhabitants which were not air-breathing were suffocated, and so the sole descendants of carboniferous fresh waters may be the land animals

I will touch very lightly on the question that interests me very much—the probability, when we find an enormously numerous and powerful group, such as the insects or the birds, predominantly of one design, that their ancestors went through some deadly ordeal in a fairly advanced stage of their history, from which only one (or very few) species survived, so that the orders and families of the group are variations on a highly specialised ancestor the general scheme of whose structure is preserved Elsewhere I have suggested [8] that in the case of the insects the ordeal was the violent flooding of the land (cataclysm) in Torridonian times, from which one or possibly two or three species of insects were the only land animals to survive The Silurian fossil evidence is now considered by entomologists to be negative, but on the other hand they find it difficult to explain the insects of the Carboniferous and Upper Devonian without assuming a long history behind them [9]

For the birds—is it possible that their ordeal was a sudden development of rapid movement in flesh-eating mammals, which massacred every bird

(excluding ostriches, penguins, and so on) except the one species which had learned to perch on a fine twig? I am too ignorant to judge or discuss this question, and am conscious that we have touched above on many questions as to which I am culpably ignorant, and seek and expect correction. My object, in thus inviting personal humiliation, has been to ask each biologist whether, in the groups of which he has knowledge, the recognition of cataclasmal selection may not explain otherwise inexplicable characteristics, as it appears to me to do in the littoral sponges.

Obituary

DR JAMES WATERSTON

THE death of James Waterston, which occurred on April 28, some weeks after a serious operation, is a severe blow to applied no less than to systematic entomology. For many years past Waterston's entomological interests, though largely concerned with the British Mallophaga (bird lice) and with the Siphonaptera (fleas), had centred chiefly in the, usually minute, Hymenoptera known comprehensively as Chalcidoidea, many of which are of extreme importance as being in the larval state parasitic in caterpillars destructive to crops, in the pests of stored grain, and in other harmful insects such as tsetse flies.

Born at Paisley on Feb 7, 1879, Waterston was educated at George Watson's College and the University of Edinburgh, where he graduated, with honours, in divinity, philosophy and science, and afterwards proceeded to his doctorate in the latter subject. After spending some years in the ministry of the Free Church of Scotland, during which he published many papers on ectoparasites, Waterston resigned his living in the Shetlands, and, in April 1914, joined the staff of the Imperial Bureau of Entomology; his interest in and work upon the Chalcidoidea date from this period. In May 1917, after receiving a temporary commission in the R A M C, Waterston was appointed entomologist to the Malaria Commission, Salonica, being afterwards mentioned in dispatches and demobilised after the Armistice with the rank of captain. On May 20, 1920, he left the service of the Imperial Bureau of Entomology and entered that of the Trustees of the British Museum, in which at the time of his death he occupied the position of assistant keeper (first class) in the Department of Entomology.

A good all round zoologist, capable botanist, and strenuous and enthusiastic worker at the groups of insects which more especially appealed to him, Waterston was also a prolific writer, and, commencing in the year 1903, published no fewer than one hundred and sixty-four entomological papers. While the majority of these more particularly concern the systematist, the list includes pamphlets on fleas and lice (in the British Museum "Economic" series), and a valuable paper on the bionomics of sand flies (*Phlebotomus*), issued in 1922 as one of the results of his field experience in Macedonia. Among the projects abruptly terminated by Waterston's untimely death is a monograph of the British Mallophaga, for which a portion of the text and many of the illustrations had already been prepared.

Waterston's wide knowledge was ever at the service of those who sought his aid, and few of those who did so and found him at work at his table in South Kensington can fail to have been struck with his marvellous gifts as a dissector of tiny insects. To see him disarticulate, and display on a microscope slide, the mouth-parts or genitalia of a Chalcid, which itself measured but a millimetre or two in length, was a lesson in technique not easily forgotten.

E E AUSTEN

MR HUGH S R ELLIOT

BY the lamentable aeroplane accident which occurred at Hampton in Middlesex on May 6, an able and popular writer on scientific and philosophical subjects has been removed from our midst at the early age of forty nine years. Mr Hugh Samuel Roger Elliot was born on April 3, 1881. His father was the Hon H F H Elliot, son of the third Earl of Minto, and he himself was a cousin of the present earl. He was educated at Eton and at Trinity College, Cambridge. But his career at Cambridge was cut short through the outbreak of the South African War in 1899, when he obtained a commission in the Coldstream Guards.

On leaving the army in 1902, Mr Elliot devoted himself largely to scientific and philosophical studies. His first considerable literary undertaking was to edit the two volumes of "The Letters of John Stuart Mill", which appeared in 1910. This piece of work he accomplished with conspicuous care and thoroughness, and his estimate of Mill's character and achievements in the introduction is remarkably just and discerning. Unfortunately, one can scarcely speak in like terms of the book he published two years later, entitled "Modern Science and the Illusions of Professor Bergson". While, no doubt, he did succeed in exhibiting some of the weaknesses of Bergson's philosophy, he had too little patience with Bergson's mode of thought to appreciate its real significance, and his criticism of it was for the most part superficial and ineffective. He was far more at home in the volume he wrote on "Herbert Spencer", which was one of a series edited by Basil Williams and published in 1917. In his younger days he had been a fervent admirer of Spencer, and although, after an interval of fifteen years, he had come to see that much of the 'synthetic

philosophy' was ill founded and false, the book is an interesting and sympathetic study of Spencer's work and personality A serious blemish in Spencer's evolution theory seemed to Mr Elliot to be the assumption of the transmission by heredity of acquired characters, an assumption which he took to be without justification He had already argued to the same effect in the introduction he wrote to his translation of Lamarck's "Philosophie Zoologique" This translation, which was done with great skill and accuracy, appeared in 1914

Mr Elliot had a rooted contempt for what he called 'metaphysics', which he stigmatised as "a maze of sesquipedalian verbiage, beyond the reach of science to defend or to refute" Probably he got his conception of 'metaphysics' from the treatment in "First Principles" of 'the Unknowable', which he regarded as altogether extraneous and unnecessary to Spencer's philosophy as a whole He himself defended a thorough going doctrine of materialism, according to which 'physical law' is universally dominant, and mind or consciousness is "only an inert accompaniment of material cerebral changes" In his later volume, "Modern Science and Materialism", which was published in 1919, he was, however, compelled to modify to some extent his earlier view

Mr Elliot was a forcible and trenchant writer, his books and essays were always readable, even when they failed to carry conviction He was happier in expounding scientific theories than in criticising philosophical ones, and his articles on social and political topics were characterised by keen insight and sagacity His materialistic doctrine is already a spent force, but his survey of Spencer's system and his account of Lamarck's contributions to biology are not likely soon to be forgotten G Dawes Hicks

Dr P A Wagner

The death of Percy Albert Wagner on Nov 11, 1929, at the early age of forty four years, removed from a larger sphere than that of South Africa one of the most prominent workers on the economic side of geology Conjointly, the South African School of Mines, Freiberg and Heidelberg, contributed to the determining of his career Much was accomplished in that relatively short life, principally among the platinum and diamond deposits of the Transvaal, and to a rather less extent in the geology and mineral resources of South-West Africa, for Dr Wagner seldom strayed in his investigations beyond the southern section of the continent His Memoirs on the "Fides-Stavoren Tinfields" (1921), on the "Iron Deposits of the Union of South Africa" (1928), and that exceptionally interesting work on "The Pretoria Salt pan, a Soda Caldera" (1922), are typical examples of the thorough—and also the clear and systematic—manner in which the subject on hand was treated

The salt-pan formed one of the 'Problems' dealt with in Wagner's presidential address to the Geological Society of South Africa in 1917 An earlier book on "The Diamond Fields of South Africa", written in 1915 (preceded in 1909 by a volume on the same subject published in Berlin), is still a standard work of reference "The Platinum Deposits and Mines of South Africa", in which the structure and petrography of the Bushveld Complex receive all but exhaustive treatment, is an outstanding example of the minute care with which he handled his subject, dealing with it, so far as was possible, from every point of view In describing these sulphide ores, he was in his element

Appointed Geologist for the Mineral Survey in 1918, Wagner left Government service in 1927 to undertake consulting work, chiefly concerned with platinum and diamonds, finding it necessary to crowd much writing into time which most men would have considered fully occupied with strictly professional matters In his last memoir for the Geological Survey, that on the "Iron Deposits", he laments that he had only two and a half months for the microscopic work and systematising and summarising the observations of the preceding ten years "The Platinum Deposits" was written hurriedly, but one looks in vain in either for those "obvious shortcomings" he saw himself in the earlier work The memoir on "The Geology and Mineral Industry of South West Africa" (1916) is a most useful compendium of original observations and the publications of other geologists, mostly German, but perhaps the broad outlines of stratigraphical geology were not altogether Wagner's *metier*, though one feels that had his bent led him in this direction, he would have accomplished much

As his field work was essentially South African, so Dr Wagner's publications are principally to be found in South African journals No paper of his appears under the ægis of the Geological Society of London or in the *Transactions* of the Institution of Mining and Metallurgy This is of small moment, his reputation was world wide, and even those of his profession who had never met him felt a keen sense of loss at his untimely death J P

We regret to announce the following deaths

Prof John N Cobb, dean of the College of Fisheries at the University of Washington, Seattle, a past president of the Pacific Fisheries Society, on Jan 13, aged sixty two years

Mr G C Dudgeon, C B E, formerly consulting agriculturist, Ministry of Agriculture, Egypt, well known for his interest in tropical agriculture and entomology, on May 4, aged sixty two years

Prof Stephen A Forbes, since 1917 chief of the Illinois State Natural History Survey, member of the U S National Academy of Sciences and past president of the American Entomological Society and of the Association of Economic Entomologists, on Mar 13, aged eighty five years

Dr Christine Ladd Franklin, lecturer in psychology and logic at Columbia University, and originator of the theory of colour vision known by her name, on Mar 5, aged eighty two years

Prof Max Matthes, director of the University Medical Clinic, Königsberg, one of the secretaries of the German Society for Natural Science and Medicine for the forthcoming meeting in Königsberg, on Mar 26, aged sixty five years

News and Views.

The organisation of the Wedgwood festival, held during the past week in Stoke on Trent, has been remarkably efficient Judging by the tremendous enthusiasm shown and the large attendances in the earlier items of the seven day programme, the Wedgwood bicentenary will leave a lasting impression on the minds of many thousands Commencing with suitable religious observances on Sunday, followed by a day of which the outstanding feature was the tremendous reception accorded to Princess Mary, succeeding days were allotted to transport, ceramics, industry, foreign trade, and Staffordshire Throughout the weekdays the remarkable historical pageant has been staged every afternoon in the most central park of the city The pageant was a great work of art embodying the musical, historical, and histrionic abilities of the district In a prologue and eight episodes, the history of the district was illustrated from the days when the early Britons stood in fear of the Roman legions in their midst up to the present day Perhaps the most interesting episode of all concerned the life of the great potter in whose honour the celebrations took place Incidents in the life of Josiah Wedgwood from the time when, as a youth, he worked at the bench as an apprentice, up to the latter days, when he had become a great industrial leader and an honoured man of science, were shown with a faithful representation of conditions and costumes which made the history live again

The modern claims of the pottery industry to world wide appreciation were splendidly upheld by an exhibition in Stoke on Trent of the products of some seventy firms, amongst whom are some of the most famous makers of china, earthenware, tiles, sanitary and electrical wares It is confidently asserted by independent witnesses that no exhibition of modern pottery of such variety and merit has been staged anywhere since the War The display of pottery of historical interest, exhibited in the Hanley Museum and including some of the choicest examples of jasper ware from H M the Queen's collection, was alone worthy of a special visit Included in this display we particularly noted one of the copies of the Portland Vase, an encaustic painted vase thrown by Wedgwood's own hand on the day in 1769 when the Etruria Works was formally opened, and a number of portraits in oils, of which one of Josiah Wedgwood by Reynolds is probably the most important The Ceramic Society, in issuing Part I of its commemorative volume, has produced a work of exceptionally varied interest Contributions from technical specialists the world over deal with a wide variety of important questions, whilst the prize essays on the contributions of Josiah Wedgwood to the technical side of the pottery industry embody new material of the greatest value

The opening on May 15 of the Electrical Research Laboratory at the Stourport works of Steatite and Porcelain Products, Limited, is a welcome sign that manufacturers now thoroughly recognise the importance of scientific research We agree with the remark made by Sir Philip Nash at the ceremony that in the future there will probably be a great network of international lines for power transmission This would bring power to our industrial centres at a price much cheaper than they can generate it for themselves The power must be transmitted at the highest possible voltage, and so the manufacture of porcelain insulators is necessary for our progress The new research laboratory at Stourport is equipped with apparatus for testing both the mechanical and electrical properties of the insulators There is a high voltage room, a mechanical laboratory, a fog room, and an open-air testing field The high voltage room covers 4300 sq ft and is 45 feet high It is equipped with a 500,000 volt testing alternator and two 450,000 volt testing transformers A pressure of a million volts can be obtained, and by connecting in cascade the pressure can be increased 20 per cent In addition, an impulse plant in which two high-voltage condensers are charged by a unidirectional current enables the effect of a direct lightning stroke to be imitated It is stated that in this way pressures of 1,800,000 volts have been obtained The unidirectional current for charging the condensers is obtained from a mechanical rectifier, which allows a voltage double that of the peak voltage of the transformer supplying the current for rectification to be obtained The tests are applied to the insulators under normal conditions and under artificial rain In addition, in the special room, investigations can be made under conditions of heavy fog, mist, salt spray, and artificial fouling by solid matter The mist is obtained by suspending the insulators in a refrigerator and then removing them to the higher temperature of the fog room

Prof Niels Bohr delivered the fourteenth Faraday lecture before the Chemical Society on May 8, the title of his discourse being "Chemistry and the Quantum Theory" Prof Bohr said that we owe to Faraday a large part of the common basis on which chemistry and physics are to day being built, in order to appreciate the situation in which we now find ourselves, we have to take account of the attitude of mind characteristic of physical and chemical research Two fundamental discoveries were those of the quantum of electricity and the quantum of action, characteristic of two different aspects of the atomic theory The discovery of the structure of the atom gives us a picture of the units of electricity, but the behaviour of these particles cannot be described by the ordinary ideas of mechanics and electricity The discovery of the quantum of action resulted from a study of statistical problems, as soon as we attempt to get an idea of what this quantum of action is, apart from the statistical view, we find it an impossible task Having referred to quanta of light, and to the modern view of the significance of line spectra, Prof Bohr said that the problem of utilising the discovery of the structural unit of the atom in explaining its properties is

difficult, for any reference to the mass of a particle requires reference to Newton's classical mechanics Interpretation of the properties of elements becomes possible if variations in the direction in space of the magnetic moment of the electron are postulated Progress has depended on the application of the cor respondence principle correlating quantum mechanics with classical mechanics, and has been facilitated by the introduction of the concept of wave mechanics

CONTINUING, Prof Bohr said that wave mechanics, conceived by De Broglie, has provided us with corre lation between the motion of a particle and wave propagation The electron is not the wave, nor can we discover its paths of motion, but we are able to determine whether an electron is or is not there Whenever we experiment on an atom, therefore, we always find it in one of its stationary states, this view of the existence of atoms in 'stationary states' has been confirmed by every experiment yet designed to test it The existence of a quantum of action leads to the position that we cannot obtain any knowledge concerning natural phenomena without influencing them by our observation According to our ordinary ideas, the electron has position and momentum, but when we attempt to prove that it is at a certain point, we find that we cannot do so without affecting its momentum Hence we can never get simultaneous knowledge of position and momentum Prof Bohr declared that this disability represents something quite fundamental, it implies that space and momen tum are in some degree mutually exclusive Similar limitations are concerned with time and energy, we cannot at the same time use the concepts of time and of conservation of energy In considering the station ary states of the atom, we are not concerned with time, and hence the idea has a large field of applica bility Referring to the work of Dirac, Prof Bohr remarked that it is never possible to measure the electric moment of a single electron The word 'electron' is losing its simple meaning A large part of the progress of physical science has been concerned with motion and mechanics, chemists, who have been largely concerned with properties, must follow so far as possible the concepts of motion At the conclusion of the lecture the president, Prof J F Thorpe, presented to Prof Bohr the Faraday Medal, the highest honour in the bestowal of the Chemical Society

MR H A STUYT's paper on "The Bavenda", de livered at the Royal Anthropological Institute on May 13, and Major Trevor's paper in the preceding week on certain survivals of pre European culture among the natives of Rhodesia, were both of noteworthy im portance in their bearing upon one side of the Zim-babwe controversy It has always been something of a stumbling-block, to some at least, in the way of the complete acceptance of the theory of the native origin of the Zimbabwe ruins, that while the culture as a whole is distinctly African—a point brought out very emphatically by the present exhibition at the British Museum—it does embody elements which appear, so far as known, something of a departure in Bantu cul ture, and at best scarcely cognate to the culture of the natives of to day On this point the observations of both Major Trevor and Mr Stuyt appear to throw some light For in culture and social and religious organisation the Bavenda show marked differences from the other native tribes of Rhodesia Major Trevor for example, noted the existence among the Bavenda of clay phallic altars in use in initiation cere monies, while Mr Stuyt directed attention to carved wooden dishes or bowls used for purposes of divina-tion ceremonies, which present a close resemblance to the shallow clay trays now exhibited from Zimbabwe It is noteworthy that the Bavenda make use of dry-stone wallings very similar in appearance to those at Zimbabwe One kraal also exhibited the remarkable and rare occurrence of a monolith erected upon it, again re calling a feature of Zimbabwe These, with many other similarities, are sufficient to point to the possibility of the Bavenda having occupied the Zimbabwe country Although copper working is not yet definitely associ ated with Zimbabwe, it is possible, for until forty or fifty years ago the Bavenda were copper workers

IN his Friday evening discourse delivered at the Royal Institution on May 16, Dr C M Yonge de-scribed the Great Barrier Reef of Australia and dis cussed some of the results obtained by the expedition under his leadership which has recently investigated its structure and biological associations The reefs are built up on a shallow platform which fringes the north east coast of Australia and is very wide in the south but narrows in the centre, to broaden out again in the region of the Torres Strait The reefs are most abun-dant near the outer side of this platform and so en-close a sheltered channel which forms the main steamer track from the eastern ports of Australia to the Far East This channel is dotted everywhere with islands, of which many are high, rocky, and of great beauty and were probably originally part of the land mass of Australia, while in the northern half of the Barrier there are great numbers of small coral islands These low woody islands, on one of which the Great Barrier Reef Expedition lived for twelve and a half months, are all situated on small reefs moulded into a crescent shape by the south easterly trade wind They each possess on the lee side a small sand 'cay' covered with trees and bushes, and on the exposed south eastern side, in the shelter of great banks of shingle, mangrove swamps The reefs of the Barrier can be divided into two series, outer and inner The former face the full force of the Pacific and are swept bare on the upper surface, while the inner reefs are a little higher and so exposed more by the tides and have occasionally small sand cays upon them There is a great abundance of coral on their outer slopes, which descend quickly into deep water, while on the sheltered lee of the reefs great pinnacles of living coral render navigation difficult This great series of reefs possesses many animals of economic value, while its powers as a natural breakwater have earned for the enclosed channel the title of Australia's Grand Canal, but it is a canal full of dangers, as frequent shipwrecks testify

IN a recent address to the Students' Section of the Institution of Electrical Engineers, Sir Thomas Purves, the engineer to the Post Office, gave an interesting account of ship shore telephony, the latest development of electrical communication engineering The service at present covers the Atlantic Ocean The main receiving station is at Baldock, about 30 miles north of London The site of the station is in the centre of a large flat plain, carefully chosen so that no roads are nearer than a quarter of a mile to the aerials This is to prevent interference from the short waves which are radiated from the ignition systems of motor cars The working wave length of the receiver can be varied continuously over the range between ten and a hundred metres The transmitting station is at Rugby and can be worked at several frequencies For short wave telephony it is necessary to maintain the transmitted frequency within limits of the order of one part in ten thousand Piezo electric quartz oscillators, therefore, are provided They are enclosed in an oven the temperature of which is automatically regulated within very narrow limits The transmitter supplies a high frequency carrier wave to the aerial with an output power of about five kilowatts The procedure of making a call is as simple as that of any long distance trunk call The charge for the service is £4 10s for three minutes plus £1 10s for each additional minute The connexion of Rugby to the London trunk exchange is by 85 miles of underground cable, and Baldock is connected by more than 30 miles of cable to the same exchange On a recent outward voyage of the S S *Majestic*, the useful period of 10 A M to 6 P M ship's time was adequately covered The output of the ship's transmitter was about two kilowatts The principal wave lengths used are 16, 24, and 36 metres, but in order to improve the communication at very short ranges, experiments on longer wave lengths are being made

MR H C LAMB, engineer to the Manchester Corporation Electricity Department, gives an interesting account of the development of the Manchester system of supply in *World Power* for March and April The public supply began in 1893 to an area of about one square mile It has now grown to fifty two square miles The initial supply was at 200 volts on the three wire system, as early electric lamps were only made for pressures of 100 volts In 1902 high pressure supply was started at 6600 volts, three phase, with conversion to direct current supply at substations In 1923 the Barton Power Station with its connected system of 33,000 volt underground mains was brought into use These transmission lines go to seven points where the current is transformed down to 6600 volts and then supplied to the distributing substations The coming of the 'grid' has affected the development of the Manchester system The grid in the north west of England and in North Wales can be divided roughly into three main rings and the Barton Station forms a pivotal point for them Just as the 6600 volt network became a secondary when the 33,000 volt supply was introduced, so now the 33,000 volt supply has become a secondary system owing to the introduction of the 132,000 volt grid It is difficult to say whether this is the final stage in the development or not It would be unsafe to prophesy The enormous power now being distributed and the absolute necessity of continuity of supply has led to the introduction of a very elaborate and complicated system of safety devices and fault clearing apparatus Mr Lamb recalls that, in the early days, all the mains were connected up directly with the generators without fuses or circuit breakers When faults occurred —and there were many—the engines groaned, the brushes on the commutators sparked violently, and the staff held their breaths as the fault burned itself clear

MANY suggestions are being made for supplying electricity on an economical basis to remote rural districts Several engineers are strongly in favour of increasing the permissible variation of the supply at the terminals of the consumer At present, if the supply company varies the pressure of supply by less than four per cent up or down, no legal action can be taken To give it permission to increase this variation to five or six per cent would in many cases diminish considerably the costs of distribution to the company without affecting in any way the great bulk of its consumers Only a few consumers on the outskirts of the network, and those near the station, would be affected, and probably the small alteration in the pressure would pass unnoticed The legal enactment necessary to provide for this change would doubtless insist that the saving effected would be reflected in the charge to the consumer On the other hand, the lamps of the consumers living near the source of supply would have a shorter life, although their efficiency would be increased The lamps of those living far from the station would have a long life and low efficiency When it is remembered that a variation of one per cent in the pressure means a variation of three or more per cent in the light given out, it will be seen that a variation of six per cent would scarcely be fair to those whose pressures are effected, although they might not notice it, as sudden changes rarely occur It would be very costly to treat every consumer equitably We see no objection to allowing a latitude of six per cent in special cases where the present rule makes a proposed scheme uneconomical and would be consumers know what to expect

A THOUGHTFUL paper by L Berkeley and Major Raven Hart on the effect of broadcasting on the development of music is printed in the *Nineteenth Century* for May They point out that the musician and the music lover of the future will be practically restricted to radio for their education, since for each one concert attended personally they will be provided with at least twenty by radio For those living in the country, the proportion will be much higher It may be objected that at the present time one concert attended is worth more than twenty heard by radio, but this is a passing phase Radio technique is making substantial advances every year, and soon radio

listeners will be nearly on the level of the concert goer. One effect of this will be that music which does not broadcast well will be more and more neglected. Bach broadcasts better than almost any other composer, and Wagner's music is very badly reproduced. Jazz, unfortunately, with its very often puerile harmony, comes through excellently. Luckily, however, there are great possibilities in connexion with broadcasting music. For example, when the composer desires a harp to give a solo, he does not need to reduce the rest of the orchestra practically to silence; all that is necessary is to move the harp nearer to the microphone. A tuning fork can make itself heard against an orchestra in a concert hall. The pianissimo quality of a solo instrument can in this way be made to dominate any orchestration. A narrator can speak through a concert performance and almost overpowering emotional effects can be produced. This was excellently illustrated on Mar. 18 of this year when Hindemith Weill's "Lindbergh's Flight" was transmitted from Berlin to London. The authors emphasise the need for immediate experimental work by musicians and broadcast engineers in close co-operation. This is already being done at the Berlin 'Wireless Academy', and the example should be followed in England. A month rarely passes in Germany without some important musical work being specially written for broadcast reproduction.

HISTORIC wireless apparatus, including early receivers and other apparatus used by Marchese Marconi and his collaborators, and an original Fleming two electrode valve, forms part of a window display at Marconi House, Strand. The Marconi aircraft transmitter, receiver, and direction finder which secured the rescue of Captain Courtney and his companions when their flying boat caught fire and was forced to descend in mid Atlantic comprise another exhibit, illustrated by a series of photographs depicting the machine on the sea and the rescue. Other photographs show comparisons between modern and early wireless stations, including a photograph of the original 2LO, and a map is shown of present day world wide cable and wireless services. In contrast with the first valve are three modern transmitting valves, one of them of the water cooled type, for broadcasting and high power wireless telegraph stations.

SCIENCE Service announces that at the recent meeting at Washington of the National Academy of Sciences the following medals were presented: Public Welfare Medal to the late Stephen T. Mather, organiser of the U.S. National Park Service and its director through the first years of its work; Daniel Giraud Elliot medal and honorarium, which is given for the most meritorious work in zoology or palæontology published each year, to Ernest Thompson Seton, whose book, "Lives of Game Animals", was selected as worthy of the prize for 1928; Agassiz Medal for oceanography to Dr. Johannes Schmidt, director of the physiological department of the Carlsberg Laboratory at Copenhagen, known for his work on the life history of the eel; Mary Clark Thompson Medal, for the most important services to geology and palæontology, to Prof. William Berryman Scott for distinguished work in palæontological research.

THE following have been elected members of the U.S. National Academy of Sciences: Prof. C. A. Adams (electrical engineering) Harvard University; Dr. J. W. Alexander (mathematics) Princeton University; Dr. Eugene T. Allen (geophysics) Carnegie Institution of Washington; Prof. Harry Bateman (mathematics) California Institute of Technology; Dr. Isaiah Bowman (geography) American Geographical Society, New York; Dr. G. P. Clinton (botany) Agricultural Experiment Station, New Haven, Conn.; Dr. William W. Coblentz (physics) U.S. Bureau of Standards; Dr. P. S. Epstein (mathematical physics) California Institute of Technology; Dr. Vernon L. Kellogg (biology) secretary of the National Research Council; Dr. F. G. Keyes (chemistry) Massachusetts Institute of Technology; Dr. K. S. Lashley (psychology) Institute of Juvenile Research, Chicago; Dr. Berthold Laufer (anthropology) Field Museum of Natural History; Dr. S. C. Lind (chemistry) University of Minnesota; Dr. Frank E. Ross (astronomy) Yerkes Observatory; and Dr. A. H. Sturtevant (biology) California Institute of Technology. Prof. R. A. Millikan, of the California Institute of Technology, has been re-elected foreign secretary of the Academy for a term of four years.

THE Second World Power Conference will be held in Berlin on June 16-25. This will be the second plenary meeting of the World Power Conference; sectional meetings have been held at Basle (1926), which dealt with the utilisation of water power and inland water ways, the London Fuel Conference of 1928, at Barcelona (1929) on water power utilisation, and at Tokyo (1929) on the development of power resources, the latter coinciding with the World Engineering Congress. The honorary patron of the 1930 Conference at Berlin is President von Hindenberg, the honorary president being Dr. Oskar von Miller, the founder of the Deutsches Museum at Munich and pioneer of the electrical supply industry, while Dr. C. Köttgen will be chairman of the Conference. The management of the Conference is in the hands of the organisation set up by the German National Committee for this purpose at the Ingenieurhaus, Berlin N.W.7. Of the 400 papers submitted, copies of which will be printed and sent out on request before the meeting, only the most important statements will be dealt with by the general reporter at the meeting itself. The discussions that then take place constitute the most valuable part of the Conference. In addition to the purely technical programme, a series of addresses on present and future power supply problems will be delivered, and on the conclusion of the Conference special facilities are being granted for visiting the most important power and industrial plants in Germany. The public lectures include one by Prof. A. S. Eddington, on "Subatomic Energy", and one by Prof. A. Einstein, on "The Physical Space and Ether Problem."

THE speech delivered by Sir Robert Hadfield, as chairman of Hadfields, Ltd., on the occasion of the

annual meeting of the company on Mar 17 last, which has recently been issued, is in refreshing contrast to the usual type of address favoured by chairmen of industrial companies It is to be wished that the directors of great industrial concerns were more frequently men of scientific attainments and experience, with an intimate knowledge of the processes and products of their undertakings As might be expected of its author, the address ranges over a wide field, from the proposed scheme of an Empire Development Board, the importance of which the chairman has striven to bring home to the public as a practical alternative to the political and fiscal remedies now so widely advertised, to the recent developments in the metallurgy of steel Sir Robert Hadfield shows some scepticism regarding modern tendencies in pure physics, but he fully recognises the value of scientific research, and records remarkable results obtained by the systematic investigation of the properties of metals After discussing the changes which have been brought about in the practice of engineering by the introduction of manganese and silicon steels, he goes on to describe the uses of the heat resisting steels which are now a special product of the firm The fact that steels are now obtainable which have an extraordinarily high resistance to oxidation even when exposed for long periods to temperatures so high as 1200° C is of the highest importance to the chemical as well as to the engineering industry

A CONVERSAZIONE of the Institution of Electrical Engineers will be held, by permission of the Trustees, at the Natural History Museum, South Kensington, on Thursday, June 12, at 8 30 11 P M

THE annual visitation of the Royal Observatory, Greenwich, will be held on Saturday, June 7, when the Observatory will be open for inspection by guests of the Board of Visitors at 3 30 P M

DR W H ECCLES will deliver his presidential address to the Institute of Physics on Tuesday, May 27, at 5 30 P M, in the rooms of the Institution of Electrical Engineers, taking as his subject "The Influence of Physical Research on the Development of Wireless" The address is open to the public without ticket

ON Wednesday, June 4, in the Physics Theatre of King's College, London, Prof T H Laby, who is home on short leave from Melbourne, will read a paper before the Faraday Society on "Qualitative and Quantitative Atomic Analysis by X rays" The subject matter of the paper is indicated in the letter by Prof Laby and Mr C E Eddy which appeared in NATURE of April 5, p 524 Invitations to attend the meeting are being sent to physicists and metallurgists, and considerable interest is likely to be aroused by the technique used by Prof Laby At the same meeting a short paper by Mr Calvert, who is working with Prof G Hevesy at Freiburg im Breisgau, will also be read

THE Council of the Institution of Electrical Engineers has made the following awards of premiums for papers read during the session 1929–30, or accepted for publication *Institution Premium* to Mr H H Harrison, *Ayrton Premium* to Messrs B A G Churcher and A J King, *John Hopkinson Premium* to Mr L C Grant, *Kelvin Premium* to Mr T G N Haldane, *Paris Premium* to Messrs H A Humphrey, D M Buist, and J W Bansall, *Extra Premiums* to Messrs S W Melsom, A N Arman, and W Bibby, Messrs E H Smythe and E G Weeks, Messrs T W Ross and H G Bell, Mr W West, Mr Bernard Leggett, Mr J C Prescott, and Mr H W Taylor *Wireless Section Premiums* *Duddell Premium* to Mr J E P Vigoureux *Extra Premiums* to Capt P P Eckersley and Mr N Ashbridge, Mr G Shearing, and Capt J W S Dorling

THE first award of research fellowships in tuberculosis provided from a fund established by a recent benefaction in memory of Dorothy Temple Cross will be made by the Medical Research Council in July, for the academic year beginning on Oct 1 Applications should be lodged with the Council not later than June 30 The object of the fellowships, as defined in the trust deed, is to give special opportunities for study and research to persons "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms" Candidates must be British subjects, and must possess suitable medical, veterinary, or scientific qualifications The fellowships will preferably be awarded to candidates who wish to conduct their studies or inquiries outside Great Britain Each fellowship will be of the value of not less than £300 per annum, with travelling expenses in addition, and will be awarded for one year It is also hoped to award one senior fellowship of considerably greater value to a well qualified candidate wishing to undertake intensive investigation into some special problem of tuberculosis Particulars are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1

THE Report of the Director General of Public Health, New South Wales, for the year 1928, which has recently been issued, records the vital statistics for 1928 and gives full information on the public health administration of the State The birth-rate was 22 59, and the death rate 9 55, per 1000 of population, being 4 5 per cent and 1 0 per cent respectively below the averages of the previous five years Deaths from pulmonary tuberculosis continue to diminish, while the deaths from cancer and heart disease are increasing year by year We miss the research articles which have been included in former reports, only one investigation (on atmospheric conditions in textile mills) being reported

MESSRS W Heffer and Sons, Ltd, Petty Cury, Cambridge, have just issued Catalogue No 348 of second hand works, over 2000 in number, dealing with zoology and biology, anthropology and ethnology, agriculture, botany and gardening, chemistry and chemical technology, geology and palæontology, mathematics and physics, physiology, anatomy and medicine, etc The catalogue should be of service to librarians and others anxious to fill up gaps in their libraries

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —Probationary assistant constructors in the Royal Corps of Naval Constructors—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (May 26) A full time engineering workshop instructor at the School of Engineering and Navigation, Poplar—The Education Officer (T 1), County Hall, S E 1 (May 26) A lecturer in biology, specially interested in sea shore life, at the Brighton Municipal Training College for Women—The Secretary, 54 Old Steine, Brighton (May 30) An advisory and research entomologist at the South Eastern Agricultural College—The Secretary, South Eastern Agricultural College, Wye, Kent (May 31) Full time lecturers in mathematics and biology at the Chelsea Polytechnic—The Principal, Chelsea Polytechnic, Manresa Road, S W 3 (May 31) A town planning assistant on the County Surveyor's staff of the Lancashire County Council—The Clerk of the County Council, County Offices, Preston (May 31) Inspectors of mine beacons in the Mines Department of Southern Rhodesia, and assistant road engineers in the Roads Department of Southern Rhodesia—The High Commissioner for Southern Rhodesia, Crown House, Aldwych, W C 2 (May 31) A full time teacher of electrical engineering at the Oldham Municipal Technical College—The Secretary for Education, Education Offices, Oldham (May 31) Two assistants at the Ditton Research Laboratory, East Malling, Kent, for making temperature observations and for running refrigerating machinery The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S W 1 (May 31) A research assistant and demonstrator in geology in the University of Leeds—The Registrar, The University, Leeds (June 2) An assistant editor of the *Pharmaceutical Journal*—The Secretary, Pharmaceutical Society of Great Britain, 16 Bloomsbury Square, W C 1 (June 2) A temporary full time physics and chemistry lecturer at the National Society's Training College for Teachers of Domestic Subjects—The Principal, National Society's Training College, Berridge House, Fortune Green Road, N W 6 (June 2) Chemists on the scientific staffs of research establishments of the Department of Scientific and Industrial Research—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S W 1 (June 6) A lecturer and head of the zoology department of the University College of the South West of England, and an assistant lecturer in the same department—The Registrar, University College, Exeter A head teacher of building construction at the Woolwich Polytechnic—The Principal, Woolwich Polytechnic, S E 18

ERRATUM—In the letter in NATURE of May 17 p 744, by Prof G Hevesy and A Guenther entitled 'Search for an Inactive Isotope of the Element 84 (Polonium)", seven lines from end should read 1 gm of each mineral examined cannot contain more than 10^{-11} gm of the element in question "

Our Astronomical Column

The Companion of Mira Ceti—Prof Aitken gives the following measures of this star in *Publ Ast Soc Pacific* for February

	P A	Dist
1923 82	130 3°	0 90″
1924 69	131 6	0 84
1925 56	128 9	0 78
1929 98	134 9	0 85
1929 99	134 5	0 87

He notes that the companion was sometimes not seen when the conditions were good, and infers that it, like the primary, is variable Its magnitude last December is given as 10

Zi-Ka-Wei Observatory—This observatory is four miles from Shanghai It was founded in the sixteenth century by the Jesuit Fathers Ricci, Schall, and Verbiest, after being long closed, it was reopened in 1873 A short illustrated history of the observatory has just been issued Warnings of typhoons were formerly given by semaphore, but for the last fifteen years they have been given by wireless The Fathers have received many testimonials of the value of these warnings, some specimens of which are reproduced Time signals are now also issued by wireless The observatory took part in the recent international determination of longitudes by wireless signals There is a photographic equatorial with aperture 15½ in, this has been used *inter alia* for the formation of an atlas of the moon in 15 plates with Chinese text The programme also includes sunspots, magnetism, and seismology, a star catalogue of 14,000 stars, and calculation of the perturbations by Jupiter of about 100 minor planets (the last by P E de la Villemarqué) The illustrations include an amusing Chinese caricature of the astronomers "looking for the second" when an earthquake stopped the clocks on May 14, 1926

Photograph of a Lunar Landscape—Many text books of descriptive astronomy contain pictures of 'ideal' lunar landscapes, which in most cases are more or less imaginary but in *L'Astronomie* for April, M M Darney reproduces a portion of a photograph taken on Feb 12 with the 22 cm equatorial at the Paris Observatory, it contains the region near the limb in the neighbourhood of Newton and Grimaldi, and is so oriented that the landscape appears much as it would be seen from a distant lunar aeroplane The slopes of the hills are seen in their true proportions, the steepest slopes in the region appear to be about 45°, but most of them are much more gentle One mountain is a simple cone without any accompanying ring, but the ring formation greatly predominates, and most of the rings appear absolutely regular and unbroken M Darney notes that it would be useful to take photographs of this kind of the regions that are generally invisible, but are occasionally brought into view at extreme libration Mr H G Tomkins is making a photographic study of the moon at his observatory at Dedham, and has photographed some of these little known regions One picture, exhibited at a meeting of the British Astronomical Association, showed a mountain with a curious appendage, resembling on an enormous scale some of the great stone blocks that have been lodged on terrestrial mountains by glacial action

Research Items

Cave Art in Palestine—In *Man* for May, Miss D A E Garrod figures and describes three objects of meso lithic age from the cave of Mugharet el Wad, which lies at the foot of Mount Carmel The cave consists of a large well lit chamber and long inner corridor facing north west and commanding a wide view of the plain In November 1928 it was found by means of trial trenches that the cave contains a very abun dant microlithic industry, without associated pottery, closely resembling the mesolithic industry found at Shubka in western Judæa in the spring of 1928 In association with this industry Mr Lambert, the excavator, found a carved bone and pierced shoulder blade The carving represents a young cervine animal fashioned partly in the round and partly in relief at the end of a fragment of some fairly large long bone The head is thrown back, possibly in the act of sucking, and the detail of the head is beautifully rendered The large eyes with well marked tear glands are very typical of the young deer Both ears are present The legs are carved in low relief on the shaft of the bone and show two series of horizontal incisions at the joint There are also a series of parallel notches on the breast, possibly intended to represent loose skin The shoulder blade which was found has a large elliptical hole cut through the thick part of the bone, close to the articular end It recalls the *baton de commandement* of western Europe The British School of Archæology took over the excavations from May to July 1929 It was found that the archæological sequence is Early Bronze, Mesolithic, Upper Palæo lithic, Capsian, Middle Aurignacian, Early Middle Aurignacian, Mousterian—the most complete pre historic sequence yet discovered in Palestine At the base of the Mesolithic was discovered a crude repre sentation of a human head shaped from a fragment of compact banded impure calcite—the first work of art of the Stone Age to be discovered in Palestine

Nature of Purposive Movement in Fishes—Under this title Mr Herbert O Bull, biologist at the Dove Marine Laboratory, Cullercoats (Report for the year ending June 30, 1929), whose most recent work on the subject has just appeared in the *Journal of the Marine Biological Association* (vol 16, No 2, March 1930), discusses the importance of such experimental work in providing information upon the factors which direct fishes in their purposive movements and so tend to explain their spawning and feeding migrations He shows from his own work how the common shanny, *Blennius pholis*, in a very short time is able to react purposively after suitable training towards a gustatory stimulus containing so little as 0 00075 per cent of its food substance dissolved in sea water With regard to those researches the author states "I now believe that it is in this diection, or in the one closely allied to it, that we shall find an answer to many of our big problems in animal behaviour, *but only if the utmost care is taken with the smallest practical details*"

Herring Researches at Cullercoats—In the Report for the year ending June 30, 1929, of the Dove Marine Laboratory, Cullercoats, Northumberland, edited by Prof A Meek, Director of the Laboratory, most of the space is taken up by the herring investigations Mr B Storrow continues his work on the same lines as in former years The East Anglian fishery in 1928 was so successful that the merchants had completed their cure before the season was finished This was due to the rich year classes of 1925 and 1922 The younger fishes arrived first and many of them were spawning The 1922 class, chiefly full fish, which arrived later, was also very abundant Its possible wealth was predicted in this report seven years ago The advent of large numbers of fish in 1927 which had joined the commercial shoals in their third year followed an abnormal flow of Gulf Stream water into the North Sea in 1926, similar to one in 1920–21 which was followed by certain alterations in behaviour of the herring shoals There is apparently a tendency since 1920–21 for North Sea herring to migrate towards the ocean at the approach of maturity, taking the fish away from the ordinary fishing grounds The greatest growth occurs with oceanic conditions In Part 2 of the herring work Mrs Cowan continues her studies on the measurements of the fish

Neuro-muscular Mechanism of the Gill of *Pecten*—Under this title (*Quart Jour Micro Sci*, vol 73, February 1930) Setna gives an account of an experimental and histological investigation of the gill of this mollusc The bases of the gill filaments are provided with two sets of non striated muscle fibres which are responsible for the movements of the lamellæ The connexions between ordinary and principal filaments contain muscle cells by means of which the movements of the filaments are brought about Each gill has four main longitudinal nerve trunks which are derived from the brain and the visceral ganglion A subsidiary branchial nerve not previously recorded in molluscs is described A branching network of nerve cells and fibres compara able with those of the mantle is scattered over the cenidial axis and the principal fibres The neuro muscular mechanism of the gill is more or less inde pendent of the rest of the body, for the principal responses may be obtained in the isolated gills The different movements of the gills in response to various stimuli are described and their significance to the feeding habits discussed

Pepper Cultivation—A general account of the history and cultivation of the pepper plant has been published by M G Kidavu and P A Venkateswaran (*Bull* 98, Agri Dept, Madras) Pepper, one of the earliest known spices in the world, is indigenous in India and was first cultivated on the Malabar coast It was one of the most important articles of trade with Europe during the Middle Ages, although it was recorded there much earlier Being a strictly tropical plant, with the jungle as its natural home, pepper requires a heavy rainfall, and when brought under cultivation thrives best on a well drained, virgin red laterite soil containing plenty of humus It is a perennial climbing plant propagated by cuttings The standards upon which the vines are trained may either be dead or living, but if the latter, it is important that care should be taken to select suitable plants, those, for example, with a deep rooting habit being essential so as to avoid competition for the surface soil water and nutrients Regulation of shading, and attention to terracing or other forms of cultivation to minimise soil denudation during the rainy season, are other important factors in pepper growing The necessity for manuring is only beginning to be con sidered, but it is already clear that the addition of humus of some kind is very beneficial In order to avoid disease, attention to drainage and the healthiness of young cuttings, and regular spraying with Bordeaux mixture are recommended The berries, after being thrashed from the spikes by treading, are dried on

mats or in prepared yards, both black and white pepper being obtained from the same plant but prepared differently As regards the economic aspect, pepper is a paying proposition, since after the initial outlay the annual expenditure is small Uniform bearing begins about the fifth or sixth year and the maximum yields are obtained from ten to twenty five year old vines, although with careful cultivation still older plants can be profitably grown

Petrology of the Izu Islands, Japan —In the *Bull Earthquake Research Inst*, Tokyo, Sept 1929, H Tsuya gives a detailed account of the island volcano Kozu shima and its rocks and discusses the geological and petrological relations of the Seven Izu Islands and the Izu Peninsula It is shown that the liparitic rocks of the Nii jima group (1) are not older than the more basic O shima group (2), both types of lavas having been extruded more or less alternately Whatever the genetic relations may be, there is now no intermediate rock type linking the two together They appear, therefore, to be of independent lineage Within each group the sequence of extrusion is as follows *Izu Peninsula* (*a*) Potash liparite → dacite → plagioliparite, (*b*) Propylite → andesite → basaltic andesite *Izu Islands* (*a*) Potash liparite → plagioliparite, (*b*) Basaltic andesite It is noteworthy that while the liparitic rocks have become progressively richer in silica, the ratio of K_2O to Na_2O has decreased The other series has become steadily more basic In these the ratio of FeO to MgO in pyroxene increases with the albite proportion in plagioclase

Core Drilling Bituminous Sands —An interesting point in connexion with methods of separation of bitumen from impregnated sands arises from recent work carried out in Alberta for the location of those deposits beneath overburden In the course of drilling through unoxidised bituminous sand, the action of cold water promoted a ready separation of the bitumen from its host, and as much as 96 per cent bitumen was recovered from one sample by scraping it from the cable tool bit Where the bituminous sand has been exposed to the action of the weather for any time, separation is not so readily effected, but it is a fact that most separation processes have been based on material taken from outcrop, that is subject to atmospheric action It would be a point of both scientific and economic importance to know what resistance to separation is manifest by bitumen which has been made to impregnate sand the constituent grains of which are coated to a greater or lesser extent by limonitic films whether, given the same degree of bituminous saturation, a non ferruginous sand (for example, glass sand) or a strongly ferruginous sand would give up its hydrocarbon content to water flush more readily Alternatively, it may not be a question of the sand grain coating at all possibly the facility of separation is a function of the freshness of the bitumen itself, for clearly where this material is exposed to the atmosphere, it undergoes changes which cannot be set up so long as it is hermetically sealed from the influence of meteoric water One cannot help feeling that both possibilities must be taken into account The report by S C Ells (Canada, Dept of Mines, 1929) dealing with the exploitation of these sands gives point to this matter from the observations made while actually drilling but the author does not discuss the significance of it in the sense outlined above

Rainfall of the World —A new rainfall map of the world is given with a paper by Dr E Ekhart in *Petermann's Mitteilungen* (Hefte 3/4, 1930) The map, which is printed in colour, shows seven isohyets valued in centimetres It is based on the ten years' observations from 1911 to 1920 inclusive from more than six hundred stations ranging from Greenland and Spitsbergen to South Georgia and the South Orkneys A noteworthy feature of the map in which respect it differs from many other rainfall maps, is that the isohyets are not confined to the land areas but are carried across the oceans By the judicious use of island stations this method has been made possible without the risk of great inaccuracy The paper contains also a number of profiles of rainfall drawn across the world on every tenth parallel of latitude from 70° N to 60° S

A Steel Triangulation Tower —A portable but rigid steel triangulation tower which has been adopted by the United States Coast and Geodetic Survey is described by the inventor, Mr J S Bilby, in *Special Publication* No 158 of the Coast and Geodetic Survey The Bilby steel tower as it is now named consists of an inner tower 90 feet in height and an outer tower 100 feet in height The inner tower is to support the instruments and the outer tower to hold the observers' tent and a lamp for distant sighting The two are not connected, and each is fixed in 5 foot anchor posts Both are triangular in section and are built of galvanised steel rods of convenient length The total weight of the tower, including anchors and anchor sills, is not more than five thousand pounds The rigidity is such that a wind velocity of 20 miles per hour will not cause the top of the inner tower to vibrate in azimuth more than 10″ If necessary, one or more of the lower sections of the tower can be omitted when the full height is not required Full details of construction and anchoring are given in the pamphlet

New Magnetic Charts for France —In 1920 the Section of Terrestrial Magnetism and Electricity of the Geodetic and Geophysical Committee for France initiated a new magnetic survey of the country, which was commenced in 1921 and completed in 1927, the general tables of magnetic elements for the 1328 stations surveyed reduced to the epoch 1924 January 1 are now published in vol 7 of the *Annales de l'Institut de Physique du Globe de l'Université de Paris* The results are also embodied in a series of isomagnetic charts for the elements *D*, *I*, *H*, *F*, *X*, *Y*, *Z* The previous magnetic survey of France, undertaken by Moureaux, was referred to the epoch Jan 1, 1896, and comprised 617 stations In a brief description accompanying the charts, it is stated that the secular magnetic variation between 1896 and 1924 is by no means uniform over France, being, indeed (for *H*), twice as great in Brittany as at Paris A detailed discussion of this and related questions is to follow later

Calibration of Tuning-forks —The February number of the Bureau of Standards *Journal of Research* contains a paper by C Moon on the precise calibration of a tuning fork by comparison with a pendulum The comparison has been made photographically, the arrangement of apparatus being such that a single film records both the frequency and amplitude of the fork, and the amplitude of the pendulum, without affecting either the vibration of the fork or pendulum, or the driving mechanism of the fork The time taken by an integral number of vibrations of the fork has been determined to 20 microseconds, and the results exhibit quite definite small changes in the frequency of the fork consequent on changes in its amplitude

when the driving power is cut off The relation between frequency and amplitude is closely linear, the magnitude of the changes involved being such that a fall in amplitude of a heavy steel fork from 2 3 mm to 0 6 mm was accompanied by a rise in frequency from 99 976 to 99 984 cycles per second The results obtained have apparently reached the ultimate accuracy possible with this, or perhaps with any method, since there is evidence of lack of perfect isochronism in either the fork or the pendulum The irregularity is thought to be due to a variable rate of the pendulum caused by microseismic vibrations of the building, but it is unlikely that this can be eliminated by working elsewhere, since work carried out by the U S Coast and Geodetic Survey (in 1894) has shown that even in such an isolated place as the summit of Pike's Peak an initially stationary short pendulum rapidly takes up a slight oscillation, the magnitude of which, in the instances mentioned, was sometimes in the neighbourhood of two minutes of arc

Raman Effect and Chemical Structure—In a lengthy paper in the *Berichte der deutschen chemischen Gesellschaft* for February, Messrs Dadieu and Kohlrausch describe the method which they have used for measuring the Raman effect upon nearly a hundred compounds and discuss the bearing of the available data upon chemical constitution It is shown that certain well known chemical groupings are characterised by definite frequencies The last section deals with an attempt to find a suitable mathematical expression for the experimental results It is recognised that measurement of Raman frequencies gives us an excellent means of expressing accurately the effect of inter atomic vibrations within the molecule, since the disturbances measured are due to vibrations of atoms or atomic groups rather than to vibrations of molecules or electrons Moreover, the lack of sensitiveness to changes in physical state renders generalisation upon problems of constitution much simpler than is the case with such physical properties as absorption spectra or molecular refraction Amongst the compounds to which special attention is given are carbon monoxide and benzene Carbon monoxide is clearly differentiated from the carbonyl grouping in organic compounds, a fact which is adduced to support the view that the two atoms in the gas are held by a triple bond The structure of benzene has already given rise to much speculation in the past The evidence of the Raman effect is, on the whole, in favour of Kekulé's formula, since the frequencies which characterise all the various linkings in the skeleton C - CH - C are identified But benzene possesses an additional frequency, which apparently coincides with one associated otherwise only with normal paraffins This line disappears when a substituent enters the nucleus unless the structure of the substituent itself can produce it, and it is suggested (i) that it may owe its origin to the complete symmetry of the unsubstituted nucleus or (ii) that the six hydrogen atoms are not all equal in value, but that one of them is different from the rest The authors admit, however, that neither of these explanations is entirely satisfactory

Cost of Underground Electrical Mains—Electrical engineers have generally considered that the cost of underground mains for transmitting electrical power was much more expensive than overhead wires In a recent paper to the Overhead Lines Association, published in the *Electrical Times* for Mar 27, Dr Ekstrom gives costs which apparently prove that for pressures not exceeding eleven kilovolts—that is, the voltage which has been standardised for rural electrification in Great Britain—the underground mains may be much the more economical The saving is effected by using a special cable laying machine This machine consists of four parts A ditch digger which digs a trench 18 inches wide and any depth up to five feet, a belt conveyor which carries the earth dug up to a swinging spout behind the machine, where it is poured back into the trench, the truck carrying the cable, which is drawn by the digger and rolls down the loose earth, and the cable conveyor which carries the cable from the drum on the cable truck to the open part of the trench behind the digger The machine is driven by a four cylinder Diesel engine and its weight is so balanced that the uniform pressure on the earth under the caterpillar tracks is only 5 pounds per square inch Eight speeds are available, four for the work of cable laying and four for travelling The digger advances at rates varying from 200 ft to 300 ft per hour and is able to cover two miles per hour in travelling from place to place It is possible to lay a maximum of about one and a half miles of cable in an eight hour day The machine has been successfully used in Sweden and a film was shown of it in operation In making his computations, Dr Ekstrom assumes that the capitalised cost of wayleaves is about £32 per mile

Concentration of Hydrogen Peroxide—Whilst it is fairly easy to obtain hydrogen peroxide of moderate strength by evaporation methods, the production of 90 per cent material has so far involved rather complicated vacuum distillation In the March number of the *Journal of the American Chemical Society*, Hurd and Puterbaugh describe a method of obtaining concentrated peroxide which consists in adding to the aqueous material about twice its volume of an immiscible hydrocarbon such as xylene or *p* cymene With xylene, the commercial 3 per cent peroxide can be concentrated to about 30 per cent strength, whilst by using *p* cymene and distilling in vacuum the 30 per cent peroxide may be concentrated to 90 per cent The vacuum of an ordinary water pump was used, the water and hydrocarbon being distilled off and more than 60 per cent of the peroxide used being left in the flask in the concentrated state Most of the remaining peroxide is found in the distillate and 91 98 per cent recovery was obtained when the distillation temperature was kept below 57° The material could then be frozen to obtain pure peroxide

Atomic Structure—We have received from Dr W Tombrock, of Bergen op Zoom (Holland), an article which he has published on the chemical atom in the conception of discontinuous matter, in which the structures of hydrogen, helium, lithium, and carbon are discussed It is assumed that the electron is a material particle of larger volume and the proton a whirl in an ether composed of simple atoms The coupling of the protons in a chemical atom alone is explained in terms of the coupling of protons in a common path of secondary orbits of motion set up by the protonic whirls, these secondary orbits appearing as circular whirlwinds round the primary protonic centres of motion They at the same time explain the circular or elliptical motions of the spinning electron Representations of such proton couplings are given for hydrogen, helium, lithium, and carbon In the case of the carbon atom, the 12 protons are coupled in groups of three and have other mutual couplings The carbon proton triad must have become stable through its combination with three other triads, thus forming the configuration of the van 't Hoff tetrahedron Ether streams through inwards at the centres of the four faces and outwards at the four corners, or vice versa

Royal Society Conversazione

THE first conversazione this year of the Royal Society was held at Burlington House on May 14, and numerous specimens and pieces of apparatus were available for inspection by the fellows and their guests

The National Institute for Medical Research (Capt S R Douglas and Dr Wilson Smith) showed specimens illustrating the effects of infectious ectromelia, a hitherto undescribed virus disease of mice The disease was recognised by the occurrence of swelling, usually of one hind foot, followed by gangrene and separation of the affected portion of the limb The death rate is high, and post mortem examination shows changes of the liver and spleen Cytoplasmic inclusion bodies occur in the epithelial cells of the skin of the feet, and in glandular cells of pancreas and salivary glands The disease was investigated by Miss J Marchal, who found it to be due to a virus which, under certain conditions, constantly passes through filters which hold back bacteria

The Department of Zoology, British Museum (Natural History), had two exhibits Mr H W Parker and Lieut Col J Stephenson showed an example of parasitisation of the frog *Phrynomerus microps* by the Oligochaete worm *Nais bauchiensis*, which was recently described before the Linnean Society (NATURE, April 19, p 621) Mr G C Robson showed a model (× 2) of *Bathothauma lyromma*, Chun, a remarkable pelagic cephalopod *Bathothauma* is the most highly specialised of all the ten armed cephalopods The only known specimens were obtained in 3000 metres off the Cape Verde Islands by the *Valdivia* Expedition, and in the Pacific

The Rothamsted Experimental Station (Dr J Henderson Smith) had a demonstration of virus disease in plants Examples were shown (*a*) of the same virus in different host plants, (*b*) of different viruses in the same host plant, (*c*) of the combination of two viruses in the one plant The intracellular inclusions characteristic of many virus diseases in animals as well as plants were illustrated The movement of virus within the plant does not normally take place in the water or transpiration stream, or across dead tissues Prof H Raistrick showed apparatus used for the quantitative study of the metabolic products of the lower fungi About 400 species of the lower fungi have been grown on a synthetic medium containing glucose and mineral salts, and metabolic products arising from glucose were shown The Low Temperature Research Station, Cambridge, had exhibits illustrating the formation of methæmoglobin in red muscle and the control of fungal wastage in citrus and other fruits by storage in an atmosphere containing acetaldehyde The rate of oxidation of hæmoglobin to methæmoglobin in red muscle depends on the pressure of oxygen, and is a maximum when this pressure is small In a superficial layer of muscle, the oxygen pressure is determined by the rate of diffusion of oxygen into the tissue and the oxygen consumption of the tissue In consequence, the discoloration of red muscle produced by the formation of methæmoglobin can be controlled by alteration in the oxygen pressure of the gas surrounding the tissue The Forest Products Research Laboratory (Department of Scientific and Industrial Research) illustrated the use of anatomical methods in investigating the technical properties of timbers The magnified image of a transverse section of the sample of wood is projected on to a screen and a pointer moving across the field records on two scales according as it is moved over a group of fibres or over other elements Calculation gives the percentage of fibres in the sample

Dr and Mrs Pole Evans showed a striking collection of illuminated coloured transparent photographs of the natural vegetation of South Africa The photographs were coloured by hand by Mrs Pole Evans, and show natural vegetation scenes of grassland, forest, and desert, and included a number of photographs of the Kalahari, showing clearly that this region is anything but a desert in the commonly accepted sense In the desert scenes, the two most remarkable plants in southern Africa are shown (1) The plant commonly known as the 'Elephant's trunk' or 'half mens' (*Pachypodium namaquanum*) a unique plant which occurs in the mountains of the Orange River Valley, and (2) *Welwitschia mirabilis*, which is only found in the deserts of western Africa The John Innes Horticultural Institution had preparations showing the chromosomes of diploid and tetraploid plants of *Primula sinensis* and *P obconica* and others illustrating 'illegitimate' pollinations (pin eye with pin eye forms and thrum eye with thrum eye) in *P obconica* showing that the pollen tubes fail to enter the stigmatic tissue Preparations were also shown of chromosomes of *Pyrus Malus* The set of 17 is made up of seven types, four of which are represented twice and three three times This unbalanced polyploid condition explains some of the special properties exhibited by the group

The Department of Geology, British Museum (Natural History) (Mr A Tindell Hopwood), showed teeth of *Synconolophus* Osborn This genus of mastodons, found in the Lower and Middle Siwaliks of India, may have ranged so far west as the Isle of Samos, though the evidence is not clear, but it is not yet known from China or from Burma The Museum also showed a skull and feet of *Diceratherium Cooki* This rhinoceros had two horns side by side on the nose Various species have been found all over western Europe and North America, and this particular one from Nebraska was small, little larger than a pig, and with somewhat the same proportions

Mr R S Whipple showed an early Italian globe – believed to be the only example known It consists of two hollow hemispheres joined internally by 'bayonet' clips and measures 9 5 cm in diameter In a dedicatory inscription it is stated that the globe was engraved by Paolo de Furlani, a well known engraver and seller of maps at Venice in the second half of the sixteenth century

The Radcliffe Observatory, Oxford, exhibited photographs of the new planet discovered at the Lowell Observatory The two enlargements shown were from plates taken on Mar 29 and April 2 with exposures of an hour The instrument employed was the 24 in refractor by Grubb

Prof E N da C Andrade illustrated the mechanism of ridge formation in a sounding tube A sphere in a sounding tube is actually the centre of a vortex system, which governs the arrangement of neighbouring spheres Three tubes, excited by valve circuits were shown, (1) formation of ridges with particles of cork dust, (2) method of formation in more detail, with light spheres a few millimetres in diameter, (3) vortex system round a single sphere Messrs Adam Hilger, Ltd, showed spectrographic equipment, including apparatus for the observation of fine structure A photograph taken by Mr D A Jackson on

a reflection echelon of fused silica with the plates platinised was shown, the reflection echelon used is of the type suggested by Mr W E Williams in which the reflecting plates of fused silica are mounted in optical contact Number of plates—25, thickness of plates, 7½ mm The resolving power for wave length 4000 A is 913,000 There was also a Fabry Perot etalon of variable separation designed by Mr F Twyman, for measuring wave lengths in the longer wave length region of the spectrum in terms of the red cadmium line or other standard lines, and for observation of the fine structure of spectrum lines towards the red end of the spectrum A spectrogram from 1850 A to 3650 A, obtained on a perfectly flat photographic plate by means of an improved quartz lens system, designed by Mr J W Perry, was also exhibited The Research Laboratories of the General Electric Company (Mr J T Randall and Mr H P Rooksby) showed X ray photographs and crystal models illustrating the structure of vitreous and amorphous solids The passage of X rays through glass gives rise to broad diffraction rings or bands Some recent results (NATURE, Mar 22, p 458) indicate that these bands can usually be accounted for if it be assumed that the glass consists of very small crystallites

The Department of Mineralogy, British Museum (Natural History) (Dr L J Spencer), showed specimens of zinc blende from Tsumeb, South West Africa, which exhibited triboluminescence to a marked degree, even when under water, it also showed brilliant fluorescence when exposed to ultra violet rays The Research Department, Woolwich, illustrated a method for examining for flaws visually by means of X rays, long cylinders, such as gun tubes or gas cylinders A fluorescent screen is viewed at a distance and suspicious marks on the interior face of a long tube may be first identified by ordinary illumination and then by the interposition of a screen The same area may be irradiated by X rays and viewed on a fluorescent screen

The Solar Physics Observatory Cambridge, and the Cambridge Instrument Company, exhibited a recording microphotometer, designed for the study of spectrograms and photographs up to a size of 12 in × 10 in Light from an incandescent lamp is concentrated on to a minute area of the plate and the transmitted light falls on a slit over a photo electric cell The photo electric current passes through a Koch resistance cell and the potential across this cell is measured by a Lindemann electrometer The pointer of the latter is projected on to the camera (bromide paper 500 mm long × 120 mm wide), and its movements correspond to the density changes which are taking place in the plate as it is traversed The plate is mounted on a carrier with three degrees of freedom, the whole carrier being moved by a motor driven screw, which also rotates the drum of the camera, so that the movement of the latter bears a definite relation to the movement of the plate Two ratios are provided, 10 to 1 and 50 to 1 The part of the plate under examination can be viewed in a separate microscope while the record is proceeding Absorption wedges are provided, so that calibration lines can be made on the record or the density of any line measured by a null method Tracings were shown which give (a) an analysis of the shape of the absorption lines of sodium (D lines) in the solar spectrum, (b) an analysis of the shape of the absorption lines of hydrogen (Balmer lines) in stellar spectra, (c) distribution of illumination in the nebula N G C 3115, this being applied to form a contour map of brightness in the nebula The National Physical Laboratory had several exhibits The Physics Department showed a multiple thermoelement type hygrometer devised for use on ships carrying refrigerated cargoes The thermojunctions are housed in a metal casing attached to the end of a hose pipe and this is lowered down a thermometer tube A stream of air is drawn past the junctions by a suction fan attached to the other end of the pipe The Metrology Department showed apparatus for friction and wear tests on pivots and jewels The pivot is mounted in a vertical spindle, and supports a disc by means of a jewel mounted at the centre of the disc The disc can be maintained stationary by means of a magnet lying on the upper surface of the disc whilst the pivot rotates The apparatus has eight spindles, so that eight tests can be carried out simultaneously Wear of the pivot and jewel surfaces occurs as the pivot rotates, and this increases the torque due to friction between the pivot and jewel The apparatus can also be used to measure this torque at any time during the progress of a wear test The Wireless Division illustrated work which has been carried out for the Radio Research Board of the Department of Scientific and Industrial Research A demonstration was given by the projection of a spot of light on a screen of the frequency analysis of a modulated continuous oscillation The method of taking aural observations of bearings on the Orfordness rotating wireless beacon was demonstrated with the aid of a special stop watch The beacon signals can also be recorded automatically on a drum rotated synchronously with the beacon A 1 kilowatt two valve transmitter suitable for generating oscillations on wave lengths between 4 and 10 metres was shown, and also a simple portable two valve receiver suitable for reception work on the same range of wave lengths The Building Research Station (Mr A F Dufton) exhibited a microvolt hour meter for the investigation of the flow of heat at a window, into or out of a room (NATURE, April 26, p 635)

Sir Robert Hadfield exhibited numerous specimens illustrating special properties and applications of ferrous alloys An electric furnace was shown in operation with heating elements of the new R H * heat resisting alloy This alloy has the high electrical resistance of 134 microhms per c c at 20° C, with a low and uniform temperature coefficient of 0 000075 per °C, this combined with remarkable resistance to heat scaling By its means furnaces of the resistance type can be maintained continuously at temperatures as high as 1200° C Specimens were shown illustrating the difference in the effect of mechanical deformation on (a) manganese steel, (b) steel containing high percentages of nickel and chromium Both in their ordinary conditions are non magnetic, while, however, the non magnetic property of the former is unaffected by cold work, the latter is rendered fairly strongly magnetic Another exhibit was a specimen excavated from the base of the Khan Baba Column, in the Bhilsa district of Gwalior State, India, dating about 30 B C, certain portions of which contain no less than 0 70 per cent of carbon Upon heating to 830° C and quenching in water, the high carbon part acquired a glass scratching hardness, the Brinell hardness figure being 652, showing that no time effect wipes out this remarkable quality of hardening by quenching

Mr L S B Leakey demonstrated the Leakey-Harper drawing machine, originally designed to facilitate the detailed drawing of human skulls The machine is suitable for drawing any objects of which an accurate drawing is required, such as fossils, pottery, palæolithic instruments, etc Among other great advantages is the fact that drawings of several different views can be made without touching the object

Early Copper and Bronze in South Africa

TWO papers dealing with the primitive working of copper in South Africa, which were presented to Section H at the South Africa meeting of the British Association, are printed in full in vol 26 of the *South African Journal of Science* The late Dr P A Wagner and Mr Hugh S Gordon deal with material obtained from ancient smelters on the farm Blauwbank, No 435, in the Waterberg district of the Transvaal from which it was deduced that the ancient metallurgists had deliberately set out to make bronze Further as the original ingot found on the site some years ago and the prills of bronze here dealt with contain nickel and arsenic in notable amounts, it has been suggested that investigation might throw light on the date of these workings in view of the fact that ancient bronze from Egypt and Mesopotamia contains nickel, and yet no very ancient site is known which could have produced the ore required to make a nickeliferous bronze

Further investigations have established the existence at Blauwbank of no fewer than forty smelting sites, two different types of furnaces, and at least four different types of slag proving that tin, iron, copper, and bronze were smelted there Chemical analysis of eleven of the supposed bronze prills and brods prove that some of them are of fairly pure copper, others of arsenical copper and copper spice, while only two contain enough tin to bring them within the definition of true bronze, and these are so rich in arsenic that the application of the term is scarcely warranted Nearly all contain some percentage of nickel The analysis of a bronze bangle from Zimbabwe also contains nickel As other bronzes from Zimbabwe and a piece of bronze from Rooiberg, found by Dr Frobenius, also contain nickel, it is possible that further investigations may show a connexion between Blauwbank and Rhodesia, especially as no ancient tin workings are known in Southern Rhodesia

On the other hand, Mr G H Stanley in a paper on "Primitive Metallurgy in South Africa", while admitting that the specimens he has examined point to a deliberate admixture of tin and copper, holds that the copper ingots are of recent native origin The specimens from Zimbabwe which were examined were in part from the Rhodesia Museum, Bulawayo, in part specimens submitted by Miss Caton Thompson from her excavations at Zimbabwe and other ruins of Rhodesia The museum specimens from Zimbabwe itself were typical tin bronzes approximating so closely to the 90 10 ratio that in all probability they were made by melting together previously smelted copper and tin No nickel was found in any, though there were traces of cobalt The metal was of excellent quality and obviously produced by skilled smelters from very fine ores Of the specimens from other sites, a slug from Renders Ruin was almost pure copper, while a bangle from Niekerk Ruins, Inyanga, contained less tin and more arsenic than the rest A spear head from Dhlo Dhlo was of intermediate position, but with neither nickel nor cobalt in detectable quantities

Miss Caton Thompson's specimens—small objects, bangles and the like—exhibited a peculiar blue green patina which suggested enamel It was, however, easily removable by dilute hydrochloric acid, leaving a very roughly corroded surface A bangle gave the analysis copper 87 43, tin 12 3, iron 0 08, nickel nil, cobalt faint trace A spherical pellet 1 4 cm in diameter showed copper 98 87, tin 0 8, bismuth 0 01, nickel nil, cobalt nil Other bangles gave an analysis of copper 89 57, tin 10 5, and a piece of thin bronze plating gave approximately the same

Excepting a brass, the only specimen to show a notable content of nickel was a specimen from Chiwona, an irregular flattened lump of metal weighing about 110 gm, evidently a smelting product The analysis was copper 96 3, arsenic 1 78, tin trace, iron 0 42, nickel 1 2, cobalt slight trace

Mr Stanley maintains that the presence of nickel is exceptional rather than characteristic Nickel is quite a common accompaniment of copper in ores of the latter, but unless its presence is commercially important, it is not usually determined or reported The analyses of ancient copper objects from Sumeria published by Prof Desch show only four with nickel exceeding 0 25 per cent the richest being 3 3 Copper and bronze objects of ancient Egyptian and Babylonian origin seldom show the presence of nickel beyond what might be considered an ordinary impurity In regard to the possibility of South Africa having been the source of ancient bronzes showing traces of nickel, he holds that such ores might have been obtained from a number of other centres, such as the Caucasus or Asia Minor, where a number of ancient workings are known, and others are probably still undiscovered

University and Educational Intelligence

CAMBRIDGE —The Ministry of Agriculture and Fisheries has offered to make a grant not exceeding £8500 in aid of the provision of additional laboratory accommodation at the field station of the Department of Animal Pathology in the University

The Appointments Committee of the Faculty of Economics and Politics has appointed E A G Robinson, of Corpus Christi College, to be University lecturer in the faculty

The Council of the Senate has recommended the establishment of a temporary professorship of colloidal physics for three years, and that the professorship be held in the first instance by Dr E K Rideal, of Trinity Hall

It is proposed to confer the honorary degree of doctor of science on Prof A Einstein, Prof M Planck, and Sir John Rose Bradford

At a special congregation of the Senate on May 17, the Right Hon Stanley Baldwin was elected Chancellor of the University in succession to Lord Balfour, who died on Mar 19

LEEDS — The Corbet Woodall scholarship in gas engineering, value £60 a year, and tenable for three and possibly four years, is being offered for competition Applications must reach the Clerk to the Senate, the University, Leeds, by June 2

LONDON —Presentation Day at the University was on May 14, the ceremony taking place in the Albert Hall The new Chancellor, Lord Beauchamp, who presided for the first time, referred in his charge to the new graduates to the re constitution of the University under the Act of 1926 In the course of next year, he said, it might be expected that the foundation stone would be laid of the buildings on the Bloomsbury site, into which the University would enter in its centenary year (1936) Another important development to which the Chancellor specially referred was the provision of a hall of residence for students The new Principal, Dr E Deller, in his Report, also referred to the re constitution "There are still some matters outstanding—the revision and (it is hoped) the simplification of our regulations, and the delegation of powers are examples—but satisfactory progress is being made" The total number of candidates for

all examinations, the Report stated, was 36,633 as against 11,937 in 1913 and 34,941 last year The candidates for first degrees were 3436 and for higher degrees 510 Of the 3436 candidates for first degrees, 2458 were internal and 1488 external students There are now 10,200 internal students Nothing of outstanding scientific interest is included in the Report, but among recent developments reference is made to the establishment of the University Observatory at Mill Hill Park and to the institution of a chair of social biology at the London School of Economics

MANCHESTER —Notice is given of the offer of a Grisedale research scholarship in either botany or zoology, the value of which is £200 Applications should reach the Registrar of the University by June 2 at the latest

---

SIR WALTER BUCHANAN RIDDELL, principal of Hertford College, Oxford, has been appointed by the Lords Commissioners of the Treasury to be chairman of the University Grants Committee in succession to the late Sir William McCormick

AN examination of candidates for the associateship of the Institute of Physics will be held in September next Applications for entry for the examination must be received by the Secretary of the Institute, 1 Lowther Gardens, S W 7, not later than July 31

A FELLOWSHIP of the annual value of £300, and tenable for two years, is being offered by the Company of Armourers and Brasiers, for research in aeronautics Applications, upon a form obtainable from the Clerk, Armourers' Hall, 81 Coleman Street, E C 2, must be sent in by, at latest, May 30

THE Empire Cotton growing Corporation is offering a number of (a) specialist studentships, and (b) agricultural studentships, particulars as to the tenure and value of which may be obtained from the Secretary of the Corporation, Millbank House, 2 Wood Street, S W 1 The Specialist Studentships are intended to enable graduates who believe that they have a leaning towards research to equip themselves for posts in which work of that type is required The Agricultural Studentships are intended to enable men to receive specialised instruction to equip them for agricultural posts in cotton growing countries, whether in Government Agricultural Departments, with commercial cotton growing companies, or under the Corporation Completed forms of application must reach the Corporation by June 4

THE Council of the Institution of Electrical Engineers has established the following scholarships, the first awards of which will be made this year *Duddell Scholarship* (annual value £150, tenable for 3 years) Each candidate must be nominated (not later than June 15) by a corporate member of the Institution The award is open to British subjects less than nineteen years of age on July 1, who have passed the matriculation examination of a British university or an examination exempting from matriculation *Ferranti Scholarship* (annual value £250, tenable for 2 years) Each candidate must be nominated (not later than Aug 15) by the professor or teacher under whom he is working or has worked The award is open to British subjects less than twenty six years of age on July 1 who are students or graduates of the Institution of not less than two years' standing Particulars can be obtained from the Secretary of the Institution, Savoy Place, London, W C 2

Historic Natural Events

May 25, 1269 Prolonged Winter —The winter of 1268–69 was very rigorous in Great Britain, northern Europe, and Germany In Alsace it was prolonged until May 25 Holinshed (1578) records that "an exceeding great frost began at St Andrew's tide (Nov 30) and continued till near Candlemas The Thames, from the bridge upwards, was so hard frozen that men and beasts passed over Ships could not enter the Thames, so merchandise was brought to London from Sandwich and other places by land" The Baltic was frozen between Gothland and the Swedish coast

May 25, 1686 Hailstorm at Ryssel (Lille) —Hailstones fell at Lille weighing from one quarter to one pound or more on May 25, 1686 One had dark brown matter in the middle, which when thrown into the fire gave a loud report The others were transparent and melted immediately The storm passed over the citadel and town, and not a pane of glass was left on the windward side Trees were broken and beaten down, and partridges and hares were killed in abundance

May 26, 1916 Eruptive Solar Prominence —A remarkable eruptive prominence, reaching the unprecedented height of 18′ (about 500,000 miles) above the sun's limb, was photographed in India with the spectroheliographs at Kodaikanal and Srinagar Between $8^h\ 6^m$ and $9^h\ 9^m$ (Indian Standard Time) the prominence rose with increasing velocity from a height of 130″ to 15′ At $9^h\ 9^m$ the bulk of the prominence had suddenly disappeared, leaving a group of bright points at a height of 13′ to 17′, at $9^h\ 22^m$ or about $1\frac{1}{4}^h$ after the first photograph, this small group of points was faintly visible 16′ to $18\frac{1}{4}$′ above the sun's limb The general movement of ascent of the prominence ranged from 80 km /sec to 290 km /sec whilst the greatest velocity of movements of points within it was 450 km /sec It may be remarked that this great eruption occurred outside the sunspot zones

May 28, 1856 Rhone Floods —Serious flooding existed in the upper Rhone and especially the Saone on May 11–20, and the waters had scarcely begun to fall before another flood set in on May 24–26 On the evening of May 28 a general heavy fall of rain began and continued for nearly forty eight hours, at several places totals of more than 4 inches in twenty four hours were recorded The floods of the Drac, the lower Isère, the upper Danube, and the Rhone at Lyons, exceeded all records, and persisted for thirty-six hours The level rose 30 feet above normal at Beaucaire, all the dykes were broken, many bridges were carried away, and the low lying parts of Lyons on the left bank were partly destroyed An enormous area was flooded between Tarascon and the sea, and all the crops were ruined

May 29, 1613 Cloudburst —An enormous 'cloud burst' occurred in Thuringen, lasting eleven hours, and was followed by unparalleled floods, remembered for a century under the name of the "Thuringian Deluge" At the same time there were great floods in Saxony, Bohemia, and Austria

May 29, 1919 Great Eclipse Prominence —A great arched prominence, nearly 300,000 miles in length and more than 100,000 miles in height, was a conspicuous naked eye object within the corona during the total solar eclipse of May 28–29—the occasion when the displacement of a ray of light caused by the gravitational field of the sun (as predicted by Einstein) was first measured This prominence, as shown by spectroheliograms taken at Cambridge, Kodaikanal, and Yerkes, had been in existence since Mar 22, and at the time of the eclipse

it was coming into view around the sun's east limb. Shortly after the eclipse had been observed in South America (about 2h G.M.T.) the prominence, hitherto of a stable character, became eruptive, and by 8¼h G.M.T. had risen to a height of more than 450,000 miles, after which it suddenly dissipated. The two columns from which it arose in latitudes 37° and 41° S. were seen at each return to the sun's limbs for two months after the eclipse.

May 29, 1920. Louth Floods.—A thunderstorm of unusual severity broke over Lincolnshire during the afternoon, accompanied by exceptionally heavy rain over the Wold country to the west and south-west of Louth. At Elkington Hall, 3 miles west of Louth, 4·69 in. was measured, of which 4·59 in. fell in three hours, and at Hallington two miles to the southward it is estimated that 6 inches fell in three hours. The river Lud rose 16 feet in fifteen minutes and a deep torrent 200 yards wide swept through the town. The damage done in Louth alone was estimated at £100,000, while the flood came as a complete surprise to most of the inhabitants who were sheltering indoors, and 22 persons were drowned. The flood was probably accentuated by the blocking of the valley by débris at a bridge just above Louth.

May 29, 1928. Shower of Fish.—Dozens of tiny red fish were found on the roof of a bungalow at Drumhirk, near Comber, Ireland, and on the ground in the vicinity. Just before the discovery of the fish there had been an exceptionally violent thunderstorm with heavy rain. There is no river in the neighbourhood, the nearest sheet of water being Strangford Lough, 2 miles distant, and it was believed that the fish had been lifted from the sea by a waterspout.

May 31, 1911. Thunderstorm at Epsom on Derby Day.—The severest thunderstorm and heaviest rainfall since records started in 1905 occurred between 5 P.M. and 8 P.M. at Epsom on May 31, 1911. The day had been humid and close, with a thunder haze gathering about 3 P.M. Thunder was heard and at 5 P.M. three distant storm centres became apparent north and north-east, north-west, and south to south-west. Two cloud currents were visible at 5 P.M., an upper one from south-west, and a lower one from north-east. Fork lightning and thunder were practically continuous. The thunder was in sharp decisive cracks, and the lightning of dazzling intensity. At 5.30 P.M. the north and south centres coalesced, and rain commenced falling in a torrent at 5.20 and continued until 6.0, 2·44 in. falling in fifty minutes. The thunder ceased at 7.59 P.M. but the lightning remained visible until 9.30 P.M. Seventeen people and four horses were killed, and three hayricks fired by lightning.

Societies and Academies.

LONDON.

Royal Society, May 15.—**M. L. E. Oliphant** and **P. B. Moon**: The liberation of electrons from metal surfaces by positive ions. When helium ions strike a metal surface they liberate electrons, the number depending upon the metal and the condition of its surface. Velocity distribution of electrons, liberated from a clean surface of molybdenum by positive ions of helium, shows a sharp cut-off at a lower limit of 2·3 volts, and a sharply defined upper limit at 20·2 volts. Maxima were observed in experimental curves at 2, 5, 6·8, 17·0, and 20·0 volts. The results can be explained quantitatively on the basis of modern theories of the metallic state.—**O. W. Richardson** and **U. Andrewes**: A comparative study of the excitation of soft X-rays from single crystal surfaces and from polycrystalline surfaces of graphite and aluminium. The curves obtained by plotting the photoelectric yield of the soft X-rays per unit thermionic current against the exciting primary voltage show discontinuous rates of increase at certain voltages which coincide with those which give similar discontinuities with the polycrystalline specimens. They are, however, fewer in number and tend to run in groups. The voltages at which the discontinuities occur appear to have a numerical structure resembling that which connects the null frequencies of band systems. The crystal curves are steeper at moderate voltages and flatter at high voltages than the polycrystalline curves.—**O. W. Richardson** and **S. Ramachandra Rao**: (1) The excitation of soft X-rays from some polycrystalline metal surfaces. Measurements have been made of large numbers of soft X-ray critical potentials for cobalt, nickel, tungsten and pure and also impure copper. Variation of photoelectric yield with magnitude of thermionic current and with inclination of anticathode is examined. Many of the inflections only appear after the targets have been heated to a high temperature.—(2) The excitation of soft X-rays from a single crystal face of nickel. The soft X-ray critical potentials for the 100 face are less numerous than for polycrystalline nickel. The total yield is also lower at high and higher at low voltages with the crystal specimen.—**S. Ramachandra Rao**: (1) Total secondary electron emission from polycrystalline nickel. Applied potentials from 1 to 550 volts were used. Several peaks are obtained below 30 volts and a large number of inflections above 30 volts. The effect of bombarding in hydrogen is also studied.—(2) Total secondary electron emission from a single crystal face of nickel. The potentials at which inflections appeared agree very well with the soft X-ray discontinuities from the same crystal face obtained by Richardson and Rao. The bearing on soft X-ray discontinuities is discussed.—**O. W. Richardson**: The emission of secondary electrons and the excitation of soft X-rays. The first act seems to be the excitation of a *structure* electron by the primary which is returned as part of the high energy group of secondaries. The low energy group and the X-rays result from the return of the excited structure electrons to the ground state. The agreement of the soft X-ray with the secondary electron breaks is accounted for since both are excitation potentials of the structure electrons. The hypothesis gives a natural explanation of the band-like structure of the discontinuities already found empirically for C and Al and here extended to Ni.—**W. A. Bone**, **L. Horton**, and **S. H. Ward**: Researches on the chemistry of coal (6). The main coal substance can be readily oxidised by means of alkaline permanganate to carbonic anhydride, acetic, oxalic, and benzene carboxylic acids; about one-third of the carbon of the coal substance appeared in C_6 rings of benzenoid acids. Under 'optimum conditions' the character and proportions of the various oxidation products do not vary much with the maturity and geological age of the coal, and colloidal 'humic acids' are formed as intermediate oxidation products. The constituents of bituminous coals mainly responsible for their 'coking propensities' are benzenoid in character, and in all probability during the 'maturing process' they developed from phenols and phenolic esters, found in immature brown coals. On carbonising coals at various temperatures up to 1000° C. their proportionate 'benzenoid' structure first increases, attaining a maximum at about 500°–600° C., but afterwards diminishes, although a completely 'carbonised' coke still retains some of it.—**L. Rosenhead**: The spread of vorticity in the wake behind a cylinder. The trail of vortices in the wake behind a cylinder is taken to be a symmetrical double row of rectilinear vortices of circular

section The stability of such a system to three dimensional disturbances is investigated There is also a discussion of the stability of an isolated recti linear vortex of circular section to three dimensional disturbances —L J Freeman The spectra of trebly ionised oxygen (O IV) and trebly ionised nitrogen (N IV) About 50 lines in the spectrum of trebly ionised oxygen (O IV) have been newly classified All the doublet and quartet terms of principal quantum number 3 have been identified In the spectrum of trebly ionised nitrogen (N IV), combinations of the $3p$ term with $3s\ ^3S$ and $3d\ ^3D$ have been observed Provisional classifications have been given for four other lines —G Temple (1) The group properties of Dirac's matrices An account of the group properties of a set of operators (A_1, A_2, A_3, A_4), with operand ψ, particularly with reference to a generalised form of Dirac's wave equation

$$\sum_{s}^{4} p_s A_s \psi + (2\pi i m c/h)\psi = 0,$$

in which the A's are not restricted to be matrices (2) The operational wave equation and the energy levels of the hydrogen atom Dirac's methods can be modified and generalised to suit an extension of his linear wave equation based on the preceding paper, which is applied to the problem of the undisturbed hydrogen atom It proves possible to obtain the energy levels, quantum numbers, and wave functions —J Hargreaves The effect of nuclear spin on the optical spectra (3) The interaction energy of the nuclear and electron magnets is calculated for the cases of nuclear spins of ½, 1, 1½, and 4½ quanta A description is also given of the hyperfine structure of the Zeeman effect, and it is found that the 'cosine' law holds The results agree very well with observations for bismuth

Geological Society, April 30 —**Emily Dix** and **A E Trueman** Some non marine lamellibranchs from the upper part of the coal measures The higher part of the *Pulchra* Zone and in the *Phillipsi* and *Tenuis* Zones are discussed Nearly all the shells found in these higher measures are members of the genus *Anthracomya*, and most of them are related to the group of *A phillipsi*, but there is evidence that another group, represented by shells which resemble *A lanceolata* Hind, occurs more rarely at widely separated horizons The sequences determined in many British coalfields are remarkably similar, and reasons are advanced for the view that at certain periods in the late Carboniferous Period there was considerable uniformity in the conditions over large parts of Britain There are also great similarities in the sequence in the upper part of the Westphalian of the Continent —**Emily Dix** The flora of the upper portion of the Coal Measures of North Staffordshire The paper deals with the distribution of fossil plants in the Upper Coal Measures, and in the upper part of the Middle Coal Measures of North Staffordshire above the horizon of the Ash Coal Few plants have hitherto been recorded from the measures for some distance below the Bassey Mine Ironstone, and the chief purpose of this paper is to give an account of these measures with the view of determining the horizon which marks the entrance of the Staffordian flora in North Staffordshire For some hundreds of feet below the Bassey Mine Ironstone the measures yield a flora in which Radstockian and Yorkian species are mingled, and therefore it is concluded that the base of the Staffordian should be drawn below the Chalky Mine Ironstone, about 400 feet below the Bassey Mine Ironstone This conclusion is of importance in the correlation of such areas as South Wales, Staffordshire, and Somerset by means of fossil plants

Society of Public Analysts, May 7 —**L H Lampitt**, **E B Hughes**, and **H S Rooke** The diastatic activity of honey Honey diastase behaves in a similar way to other enzymes under varying conditions of temperature and pH, the optimum pH for both the dextrinogen amylase and the saccharogen amylase being about 5 3 —**A R Powell** and **W R Schoeller** A new method for the separation of titanium from zirconium and hafnium The method is based on the precipitation of the titania by tannin from a neutralised oxalate solution half saturated with ammonium chloride a repetition of the procedure results in the quantitative precipitation of the titania with only traces of zirconia, if any —**E R Bolton** and **K A Williams** The composition and polymerisation of Chinese wood (tung) oil The authors confirm the value of Toms's method of determining the elæostearic acid in tung oil by the difference between the iodine value obtained by the bromine vapour and that obtained by the action of Wijs solution until four of the six bonds are saturated The elæostearic acid glyceride corresponded with the amount of polymerisable matter separated by the authors' method of extraction, and for the oils examined ranged from 70 to 74 per cent —**D R Wood** The examination of milk for tubercle bacilli A survey is given of the experience and results obtained in the examination of 1000 herds in the County of Somerset during the last four years Present methods are inadequate for the elimination of tuberculous milk

DUBLIN

Royal Dublin Society, April 29 —**J Reilly**, **R Wolter**, and **P P Donovan** Study of the polysaccharides (3) Acetamide as a polysaccharide solvent —**J H J Poole** A new form of recording galvanometer A transparent scale about 4 cm long at a distance of about 10 cm is employed instead of the usual 50 cm scale at 100 cm distance A small lamp with a condensing lens behind the scale illuminates the latter uniformly After reflection in the galvanometer mirror, which is preferably plane, an image of a short portion of the scale is formed on a film of a Baby Pathe kinematograph camera at a convenient distance—say 20 cm —by means of a good lens A fine wire almost in contact with the film casts a shadow the reading of which on the scale measures the galvanometer deflection A mechanical device which causes one exposure per minute (or at any other convenient interval) enables a permanent record to be obtained The method is cheaper than the more usual revolving drum apparatus as it employs standard commercial articles The camera may be replaced by an eyepiece with cross wires for direct observation The method is then well adapted for observing the deflections of sensitive portable galvanometers for outdoor work In this case the lamp and condensing lens may generally be omitted and the scale illuminated by daylight

PARIS

Academy of Sciences, April 7 —**Ernest Esclangon** The new celestial body discovered at the Lowell Observatory Data worked out from photographs taken at the Paris Observatory between Mar 26 and April 4 —**H Deslandres** A new cause which intervenes in increasing or modifying the intensity of lines and bands in the spectra of atoms and molecules —**Marcel Brillouin** Dynamical tides with continents The law of any depth Attraction of the ring —**Charles Richet** and **Michel Faguet** The action of irradiated sea water on lactic fermentation After ten minutes irradiation, there is an acceleration of the fermentation as measured by the acidity produced

after thirty minutes irradiation there is an inversion, no acceleration being produced —**C Gutton** The properties of ionised gases in electromagnetic fields of high frequency The observations described confirm the explanation given by H Gutton of the results of his researches It is suggested that the formula of Eccles and the theories based on it require modification —**E Mathias** The conception of Stephen Gray on the identity of lightning and the sparks of electric machines In one respect the view of Stephen Gray is imperfect, lightning transports only positive electricity, whereas the induction spark is formed of two discharges in opposite directions —**L Léger** *Sphærospora pernicialis*, a new Myxosporidium pathogenic to the tench —**J Dieudonné** The roots of algebraic equations —**L Escande** The excess pressure caused by the stopping of a motor pump group in a water main —**F Baldet** The calculation of the photometric diameter of the celestial body of the Lowell Observatory (see NATURE, May 3, p 672) —**Jean Jacques Trillat** Researches on the internal and superficial structure of organic liquids with long chains The results of an X ray study, with special precautions against the errors due to the presence of a halo arising from the filtration of the continuous background In several cases, the superficial structure of liquids differs from the internal structure, as a result of a statistical orientation of the molecules The results of McBain and of Hardy are confirmed —**H Mutel** The measurement of the effective intensity of high frequency currents Experiments with a differential ammeter consisting of two glass tubes arranged as arms of a differential air thermometer with a fine platinum wire in the axis of each One carries the high frequency current and is balanced by a direct current Even after correction for the skin effect for very high frequencies there is an error due to the heating of the heat insulation material by the high frequency electromagnetic field —**J Urbanek** The diffusion of light by polished surfaces A description of a photographic method serving to characterise the perfection of polishing of a vitreous surface —**C Marie and Gérard** The electrolytic deposit of copper in the presence of amino acids Copper deposited electrolytically from a solution of copper sulphate containing glycocoll, contains both copper sulphate and the amino acid Leucine behaves similarly —**Guy Emschwiller** The photolysis of the organic iodides the influence of temperature The temperature coefficient of the photolysis varies with the nature of the radiation The phenomena are complicated and experimental verification of the theories suggested to explain the existence of a temperature coefficient of photochemical reactions is difficult —**Augustin Boutaric and Mlle Geneviève Perreau** The flocculation produced by the mixture of two colloidal solutions of the same nature but the granules of which have opposite electric signs —**F Bourion and Mlle O Hun** The determination, by the boiling-point method, of the molecular equilibria of pyrocatechol in solutions of potassium and sodium chloride —**J Golse** The action of silver nitrate on solutions of potassium mercuric iodide —**A Travers and Avenet** The estimation of phenols in coke oven effluents —**Albert Kirrmann and Jean Grard** An abnormal reaction of the dihalogen propylenes 1, 3 dibromopropylene, in a previous communication, has been shown to react in an anomalous manner with organo magnesium compounds the 3, 3 dichloro propylene is now found to behave similarly —**Roger Dolique** The normal *n* butylbenzyl and dibenzyl ethyl alcohols, the isomers methyl *n* butylbenzyl and ethyldibenzylcarbinols —**Mlle M Cabanac** The catalytic decomposition of some acetals of the fatty series by metallic oxides Diethylacetal, at 400° C in the presence of thoria, gives the unsaturated ether $CH_2=CH \cdot O \cdot C_2H_5$ (13 per cent) together with aldehyde, alcohol, and a gaseous mixture of ethylene, hydrogen, carbon monoxide, carbon dioxide, and methane —**Albert Nodon** The effects of ionisation by solar action — **H Colin and E Guéguen** The seasonal variations of the proportion of sugar in the Florideæ — **H Belval** The transformations of the glucides in the banana the formation of starch in the fruits —**Mlle Germaine Py** The evolution of the cytoplasmic constituents during the formation of pollen grains and of the nutrient layer in *Senecio vulgaris* —**F Maignon and Ch Grandclaude** The hardening action of intravenous injections of glycerol Sensitising effects of a single injection —**L Lutz** The soluble ferments secreted by the Hymenomycetes fungi Hydrolysis of the hemicelluloses —**A Paillot** Bactorial parasitism and symbiosis in *Aphis mali*

Diary of Societies

FRIDAY, MAY 23

PHYSICAL SOCIETY (at Imperial College of Science and Technology) at 3 and 5 15 —*Discussion on Magnetism* —Sir Alfred Ewing Ferro Magnetism and Hysteresis —Dr E C Stoner Magnetism in the 20th Century —Prof H S Allen Magnetism and the Quantum Theory — Prof C G Darwin The Polarisation of the Electron —W Sucksmith The Gyromagnetic Effect and Paramagnetism —F C Powell On the Change in Size of a Ferromagnetic at the Curie Point —Prof W Peddie Magnetisation and Temperature in Crystals —Prof W Weiss and Dr R Forrer Sur l'aimantation à saturation des ferrocobalts et des nickel cobalts et les moments atomiques des trois métaux —Prof W Gerlach Über neue Zusammenhänge von magnetischen u elektrischen Erscheinungen —Dr P Kapitza Methods of Experimenting in Strong Magnetic Fields —Dr W L Webster On Magnetostriction and Change of Resistance in Single Crystals of Iron and Nickel —Dr L F Bates Observations on the Specific Heats of Ferromagnetic Substances

INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Section) (jointly with Edinburgh and East of Scotland and Glasgow Sections of Society of Chemical Industry) (at Heriot Watt College, Edinburgh), at 6 —Prof J Kendall Chemistry in Naval Warfare

ROYAL SOCIETY OF MEDICINE (Epidemiology Section) (Annual General Meeting), at 8 —Dr P Stocks Infectiousness and Immunity in Regard to Chickenpox, Whooping Cough Diphtheria Scarlet Fever and Measles

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —R S Whipple Some Scientific Instrument Makers of the 18th Century

SATURDAY, MAY 24

LINNEAN SOCIETY OF LONDON at 5 —Anniversary Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) (at Leamington Spa)

INSTITUTE OF CHEMISTRY (Edinburgh and East of Scotland Section) (jointly with Edinburgh and East of Scotland and Glasgow Sections of Society of Chemical Industry) (at Edinburgh) (continued from May 23)

MONDAY, MAY 26

ROYAL SOCIETY, EDINBURGH, at 4 30 —Prof Niels Bohr Philosophical Aspects of Atomic Theory (Address and Presentation of the James Scott Prize)

VICTORIA INSTITUTE (at Central Buildings Westminster) at 4 30 —I Cohen The Jews under the Palestine Mandate

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —C L Woolley Recent Excavations at Ur

SOCIETY OF GLASS TECHNOLOGY (jointly with Deutsche Glastechnische Gesellschaft) (*May 26 to June 3*)

TUESDAY, MAY 27

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5 —Annual General Meeting

INSTITUTE OF PHYSICS (at Institution of Electrical Engineers), at 5 30 — Dr W H Eccles The Influence of Physical Research on the Development of Wireless (Presidential Address)

QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street W 1), at 7 30 — Pond Life Exhibition

ROYAL ANTHROPOLOGICAL INSTITUTE at 8 30 —W P Rowe Art and Anthropology

WEDNESDAY, MAY 28

ROYAL SOCIETY OF MEDICINE (Comparative Medicine Section), at 5 — Annual General Meeting

ROYAL STATISTICAL SOCIETY (at Royal Society of Arts), at 5 15

GEOLOGICAL SOCIETY OF LONDON, at 5 30

ROYAL SOCIETY OF ARTS, at 8 —H Barnard The Father of English Pottery — Josiah Wedgwood, F R S, Potter, Inventor, and Man of Science

THURSDAY, MAY 29

ROYAL SOCIETY, at 4 30 —Prof R Robinson The Molecular Structure of Strychnine and Brucine (Bakerian Lecture)

FRIDAY, MAY 30

ROYAL SOCIETY OF MEDICINE (Disease in Children Section), at 5 — Annual General Meeting

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts) at 6 30 —H R Ricardo The Development and Progress of Aircraft Engines

ROYAL SANITARY INSTITUTE (in Public Halls Blackburn) at 7 —Dr J J Buchan and others Discussion on The Re organisation of Poor Law Hospitals under the Local Government Act

GEOLOGISTS' ASSOCIATION (at University College) at 7 30 —S Hall A Study of the Coastal Geology between Marazion and Porthleven, Cornwall (Lecture) —Dr W G Shannon and L G Annis The Igneous intrusions of the Stoke Fleming Area South Devon

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir H C Harold Carpenter The Metal Crystal

SATURDAY, MAY 31

ROYAL SANITARY INSTITUTE (in Public Halls Blackburn) at 10 45 A M — Dr V T Thierens and others Discussion on The Need for Further Legal Powers with Respect to Ice Cream —H W Webb and others Discussion on The Provision and Maintenance of Dustbins—Private or Municipal

PUBLIC LECTURES

MONDAY MAY 26

LONDON SCHOOL OF ECONOMICS at 6 —Prof C Burt The Measurement of Mental Capacities (Succeeding Lectures on June 2 and 16)

TUESDAY MAY 27

SIR JOHN CASS TECHNICAL INSTITUTE at 7 —G Patchin Micro Examination of Engineering Metals and Alloys (Armourers and Brasiers Company Lectures) (Succeeding Lectures on June 3 and 10)

WEDNESDAY MAY 28

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE at 5 30 —Lt Col G E F Stammers Lecture and Demonstration on Tropical Hygiene (Succeeding Lectures and Demonstrations on May 29 30 June 2 3 4 5 and 6)

THURSDAY, MAY 29

CHELSEA PHYSIC GARDEN (Swan Walk Chelsea), at [illegible] —Dr A W Hill Cabbages and Kings (Chadwick Lecture)

INSTITUTE OF PATHOLOGY AND RESEARCH ST MARY'S HOSPITAL PADDINGTON, at 5 —Sir Thomas Lewis Reactions of the Skin to Cold

FRIDAY, MAY 30

UNIVERSITY COLLEGE at 5 30 —Prof G H Parker The Secretory Action of the Nervous System

CONGRESSES

MAY 26 TO 28

CONGRESS OF LEGAL MEDICINE (at Paris)

MAY 28 TO JUNE 1

GERMAN BUNSEN SOCIETY (Deutsche Bunsen Gesellschaft) (at Heidelberg) —Principal Subject for Discussion Spectroscopy and the Structure of Molecules

MAY 28 29 30, and 31

SOUTH EASTERN UNION OF SCIENTIFIC SOCIETIES (at Portsmouth)

Wednesday, May 28, at 8 P M (at Municipal College) —O G S Crawford What is Archæology ? (Presidential Address)

Thursday, May 29, at 11 A M —Alderman W E St. Lawrence Finny The Crusades and Pilgrimages

At 12 noon —Prof L S Palmer Some Correlations between the pre History of Hampshire and Africa

At 11 A M —Lt Col A H Wolley Dod: The Experiences of a Field Botanist

At 11 45 A M —Miss C M Gibson Paper

At 12 30 —Sir M Abbot-Anderson Resolution on the Preservation of Wild Flowers

Friday May 30 at 10 A M —H Dewey Cornish Geology and Scenery, with a Few Remarks on the Isle of Wight by Way of Comparison

At 11 A M —Lt Col J H Cooke Origin of Scenery in the Portsmouth District Geologically Considered

At 12 noon —Prof L S Palmer Recent Geology of the Portsmouth District

At 10 A M —J F Marshall The Organisation of Mosquito Control Work

At 11 A M —Miss G F Selwood Observations on Fauna Changes in a Bog at Bembridge, I W

At 8 P M —L B Benny Progress in Astronomy

Saturday, May 31, at 10 A M —G E Hutchings Some Applications of Regional Survey in Education.

At 10 45 A M —A Farquharson A Regional Survey of Chichester

At 11 30 A M —D H Thomson Springs, Streams, and Wells in the Portsmouth District

SATURDAY, MAY 31, 1930

The Position of Fundamental Research

THE current report of the Medical Research Council directs attention to the present dearth of men able and willing to devote themselves to clinical research in experimental medicine In spite of the success which has attended the appointment in 1916 of Sir Thomas Lewis to organise work in clinical medicine—an experimental appointment which it may be noted in passing has been responsible for an output of valuable work on the scientific study of the heart and blood vascular system, its disorders and their treatment which has constituted the main stream of international progress in these subjects—it has been very difficult to find suitable men for appointment to the necessary assistantships This shortage of recruits of high attainments for scientific research work retards seriously the general progress of medical research Immediate opportunities for research in the hospitals are being wasted while the present system yields no proper supply of men qualified to undertake research elsewhere in the modern conditions required for scientific progress

A similar situation has been reported from France, and in post War Europe generally there has been a very marked shortage of candidates for careers of pure and experimental science, as compared with careers in applied science Progress in applied science depends upon fundamental scientific experimental investigation, and the concern of the Association of British Chemical Manufacturers in regard to the chair of organic chemistry at University College, London, is primarily due to realisation of this fact The awkward situation has revealed the unfortunate fact that not even a handsome salary has been able to attract a really first class organic chemist of the younger generation

Replacement of a chair of organic chemistry by one of physical chemistry may have grave consequences for the chemical industry of Great Britain and tend towards that same neglect of organic chemistry which fifty years ago was primarily responsible for our dependence on foreign countries for synthetic dyestuffs, drugs, etc Much more serious for mankind generally will be the consequences of neglecting the present international situation, and if no inquiry is made into the contributory causes of the shortage of recruits for professions of scientific research or attempt directed towards their removal

The International Committee on Intellectual Co operation, however, has been devoting some attention to this problem, and it was early realised that

the underlying causes are similar in most countries Prominent among these is the very different position offered to those who adopt a career of scientific research, whether in medicine, chemistry, or other branches of science, as compared with those offered in the field of applied science While the intellectual demands made upon the research worker may be, if anything, more severe than those made upon his colleagues in professional or industrial practice —he must have his problems in mind during most of his waking hours and be thoroughly versed in the scientific literature of all countries—his prospects are much inferior Brilliant success in research, even if measured by high international standards of value, will bring him no more than a moderate salary On the other hand, in medical practice, for example, merely moderate ability combined with good luck may make him a rich man, and even in Great Britain the opportunities for the chemist or physicist who adopts an industrial career or takes up consulting work to attain positions of high responsibility and remuneration are far greater than those of one who adopts a career of scientific research Even in industry there are many tendencies which act to remove the ablest investigators from the sphere of research, the normal avenue of advance or promotion being to administrative positions and away from laboratory work

Until there are a reasonable number of positions in the various branches of scientific research the occupation of which at middle age provides reasonable remuneration and adequate power of educating a family, the successful recruitment of young men of ability for experimental research cannot be maintained It must be realised, too, that young men of the type required will not be attracted if the promotion open to them is to positions which carry such burdens of teaching and administration as to debar them from the research work that it is their ambition to pursue In the words of the Balfour special research sub committee reporting to the last Imperial Conference "Special inducements offered at any early stage to tempt young men into a profession cannot make up for inherent deficiencies in the prospects which that profession can provide in salary, promotion, status, and opportunities "

To stress this point does not deny that the main driving force of research work of any high standard is scientific enthusiasm The real stimulus will always be primarily intellectual, but that stimulus cannot operate effectively if the investigator is too much occupied either with the struggle to secure and maintain a reasonable standard of living or with the discharge of administrative or tutorial duties Major F A Freeth alludes to this danger in his May Lecture to the Institute of Metals on "The Influence of Technique on Research", and he would be the first to admit that in the team work which industrial research demands under modern conditions, enthusiasm is as important a factor as a high standard of technique

It is to this latter factor that Major Freeth devotes most attention in the lecture to which reference has just been made One of the weakest spots in research in Great Britain to day, he asserts, is the totally disproportionate strength on the side of technique as against the numbers and efforts of people who are engaged in research, and the experimental facilities of the average university or research institution, industrial or not, are not nearly so effective as they could easily be This is true of other countries, notably of Austria, Czechoslovakia, Poland, Hungary, Russia, where remarkably fine experimental work has been carried out during the post War years under most discouraging conditions by a number of men of science whose work is only just receiving recognition The fundamental cause is the same everywhere—a shortage of men and a shortage of money, varying in acuteness from country to country There are, of course, a few brilliant exceptions, for example, Holland, where the foresight of Prof Kamerlingh Onnes led to the development, through the Instrument Makers' School at Leyden, of the technique and technicians required for his attack on the physics of low temperatures Again, in Great Britain, the wisdom and initiative of Imperial Chemical Industries, Ltd, have supplied the apparatus and equipment that have made possible the remarkably successful work in physical chemistry and in high pressure reactions at the Imperial College of Science and Technology and elsewhere

The future of fundamental research is, as Major Freeth suggests, dependent largely upon our ability to raise either from the community or from powerful individuals the money required for the development of adequate technique and resources It is dependent also on our ability to stimulate the maximum intellectual interest and enthusiasm of our experimental investigators It is dependent, too, upon our ability to reward the brilliant prosecution of laboratory work with recognition both in pay and in status which can compare with that which rewards similar abilty in administrative and other spheres of intellectual life The effort of the Medical Research Council to deal with this situation, not only by helping recruits of ability

during their preliminary period of training and probationary work, but also by increasing the number of stable positions in which the career of clinical research can be pursued with proper facilities and reasonable remuneration, for example, by increasing the number of clinical workers upon their staff as suitable candidates are available, is one that deserves support It means an immense contribution to the alleviation of human suffering, and renders possible the utilisation for the benefit of posterity of a wealth of experience which at present is being wasted

Medical research is, however, only one section of the field in which the shortage of recruits is so serious a problem While national efforts must play a great part in solving the problem, the efforts of such an international organisation as the Committee on Intellectual Co operation of the League of Nations may not only stimulate national effort but also may make important direct contributions Wisely directed, such a Committee can do much to bring the different national groups of scientific workers, or even the different classes of research workers, into closer touch with one another, to facilitate the exchange of technique, and by encouraging travel, remove some of the worst consequences of modern scientific specialisation It can assist materially in raising the status of the investigator in experimental science and in securing a more widespread appreciation of the importance of his work and its contribution to human progress—both fundamental factors in fostering that scientific enthusiasm and intellectual stimulus upon which fundamental research of the highest class so closely depends

The Doctrine of Atomic Valency

August Kekulé Von Richard Anschutz Band 1 *Leben und Wirken* Mit Titelbild, 119 Abbildungen im Text und auf 20 Tafeln und einem Faksimile Pp xxiii + 708 Band 2 *Abhandlungen, Berichte, Kritiken, Artikel, Reden* Mit 5 Abbildungen im Text und 3 Tafeln Pp xvi + 960 (Berlin Verlag Chemie, G m b H , 1929) Preis M 120 , M 90 to Fellows of the German Chemical Society, if ordered directly from the publisher Weight about 7 lb 10 oz

"IT was set down many years past and was the sense of my conceptions at that time, not an immutable law unto my advancing judgment at all times , and therefore there might be many things therein plausible unto my passed apprehension which are not agreeable unto my present self There are many things delivered rhetorically, many expressions therein merely topical and as they best illustrate my intention , and therefore also there are many things to be taken in a soft and flexible sense and not to be called unto the rigid test of reason Lastly, all that is contained therein is in submission unto maturer discernments "—Sir Thomas Browne—Preface to ' Religio Medici "

Such doctrine may well be applied to our ' Religio Chemici ", particularly in dealing with a work such as that under notice In terms which can only be spoken of as pathetic, Prof Anschutz presents these two massive volumes to us as the completion of a task piously undertaken thirty three years ago, at the time of Kekulé's death, at the request of Emil Fischer, on behalf of the German Chemical Society It is impossible to overrate the value of the service our German colleague renders to his cloth in this his centenary gift Few know how great are the difficulties of writing real biography, the heart searchings attending the desire to compose a truthful picture, with balanced judgment From my own experience, I can form a fair estimate at what great cost of effort this likeness has been limned

Were there not so much barium in it, the first volume might be said to be worth its weight in gold The price charged, however, is beyond that penniless, pensionless English professors can afford to pay Why German scientific books are now so very expensive is a mystery—and a misfortune Libraries even are ceasing to purchase them

No self respecting chemical librarian should be without the books No chemist's biography yet written is of greater interest and importance it is, however, necessarily very difficult reading , few of the younger generation will be able to grasp the story in its entirety , so many and such diverse and dominant characters cross the stage and so much is told of disputes, which, if not due to misunderstanding, were at least due to a failure of those concerned to understand one another and be in sympathy or, indeed, show any real sense of humour We are in face of a play of commanding and rather irascible intellects, very difficult to interpret without considerable experience of life and personal knowledge of the men concerned, as well as of the times in which they moved—the more so, as the plot is laid not in one country but in three, England, France and Germany, leading characters being drawn from all three Having known most of the chief actors, I probably am in a better position than most to carry a thread through the labyrinth to its core to give some weight to the many personal equations involved in the story

Kekulé was a born collector Prof Anschütz

has been fortunate in having a large amount of documentary evidence at his disposal in the correspondence he preserved, also the help of many who knew the man Not a few hitherto doubtful points in chemical history are cleared up in the course of the recital The task of writing such a memoir must have been a heavy one, though clearly a labour of love We cannot be too grateful for the work, having long awaited its appearance, our patience is amply rewarded in most respects, not in all

The account is written throughout upon the serious side we scarcely learn enough of the man apart from his work, in his leisure and social moments He was born in 1829 and died in 1896 His origin, his upbringing, his character, his unceasing activity as a laboratory and literary worker are clearly displayed, the problems he dealt with a'ɔ all stated yet no sufficiently vivid picture is drawn of the man himself—otherwise than incidentally—enabling those who did not know him quite to understand his magic personality We do not hear enough of his entourage—of the wild pranks of some—of which I have heard Dewar relate The book is one which a general historian could scarcely read—even a Lytton Strachey could make little of it yet the story will be found full of fascination to the expert Fortunately, a number of photographs, taken at different periods of Kekulé's life, are reproduced, which are of great psychological value One charm of the work is the large number of photographic reproductions it contains to them it owes its weight Nearly everyone referred to is pictured

The leading theme is the part played by Kekulé in establishing the basic doctrine of chemical structure—that of atomic valency (1857) The subject is treated with a rather heavy hand Anschutz, in fact, claims (as indeed did the subject of the memoir himself, originally, I have no doubt in perfect sincerity—young people who 'hear voices' are prone to think that they come to them alone) that Kekulé was essentially the first to recognise and formulate its rules not merely that he developed the doctrine specially in relation to carbon, the view that is generally held Frankland is simply denied all credit Williamson and Odling are favourably mentioned and Gerhardt is seen standing *in loco parentis* in the dim background Kekulé, with Williamson and Odling, were, we know, lineal descendants of the Laurent Gerhardt school Frankland and Kolbe were of another stock, dating back to the Stockholm stable, the main seat of chemical philosophy in the early post-Lavoisier period Some day, probably, when the Arrhenic ion is no longer our ikon, we shall return more to the worship of Berzelius—if meanwhile we do not lose our power to interpret the language of his period, as we have that of the phlogistic period, of which we have warning already in Kekulé's difficulty in understanding Kolbe Prof Anschutz has much to say of Kolbe's *Grobheit* towards Kekulé, which he bitterly resents, without attempting to explain it Kolbe was greatly affected by the 1870 war, which made him a most violent nationalist and '*Franzosen fresser*' I suppose I am one of the very few alive who knew him I can never think of him in terms other than those of admiration and affection In writing (1927) a review of the period for the *Chemiker Zeitung* on the occasion of its jubilee, I took occasion to speak out on his behalf and recall the greatness of his service I have since heard from German colleagues, that they were surprised by my advocacy Kolbe is chiefly known to day by his attacks on Kekulé and van 't Hoff the fundamental importance of his work is overlooked Some day when—as Sir Thomas Browne might urge us to do—we omit the 'improperations and terms of scurrility' which he launched at Kekulé, he may come to be regarded as the parent of the modern system of resolved structural formulæ we here have to thank him for having made Frankland, whose senior he was, what he became When I left him early in 1870, he was already peculiar he afterwards, in his last years, so fixed his mind upon certain grievances as to be little short of a monomaniac

No four men could have been more different than were Frankland, Kolbe, Hofmann and Kekulé Hofmann was the complete courtier and diplomatist, a man of the most engaging and sympathetic manners, gifted with a marvellous enthusiasm for his subject Kekulé was a born aristocrat in manner An intellectual of a high order, many sided in his interests, he was too critical and cynical to be a leader of men in the way that Hofmann was, though even superior to him as an orator, he attracted through his clear cut talent, his gift of precise speech and his great command of knowledge He had an astounding memory Frankland was a man of eminently simple, retiring nature, with a strong practical outlook, a demon worker but in no way eloquent Kolbe was equally simple, never a man of the world, a good lecturer and a far better writer but not an orator the best chemist of them all. Hofmann and Kekulé were cosmopolitans, Frankland was ever the plain, high souled Lancashireman, Kolbe—just the dear old German, academic peda-

gogue of the highest class: there is no other way of describing him.

Nothing is more certain than that most of us only take in new ideas through experience—the want must be felt before it can be satisfied. Once assimilated, an idea is expelled or modified with great difficulty. It is this that makes scientific thought, the scientific habit of mind, so difficult of attainment. Kekulé at once fell a victim to Gerhardt's magic influence, when he met him in Paris. His belief in Gerhardt's system became strengthened, in London, through association with Williamson and Odling. He does not seem to have been intimate with Frankland. He appears to have been so satisfied of the superiority of Gerhardt's system, that he took little, if any, notice of Kolbe's work. I do not believe that he ever mastered the inner meaning of Kolbe's formulæ. Kolbe had little use for the Gerhardt formulæ, knowing that he had penetrated deeper than they carried him. I feel sure he resented the way in which he and Frankland were waved aside by Kekulé and probably, this was the subconscious, if not conscious, primary cause of the bitterness he displayed towards him, in later life. In addition, he was a linguistic purist and idealist and was greatly annoyed by Kekulé's at times flamboyant masterful style. As I have said elsewhere, Kolbe's doctrine was ever the Pauline "Alles prüfen"—Prove all things! He took exception, therefore, to what he thought to be Kekulé's dogmatic, if not arrogant, declarations. Intellectually, Kekulé probably was Kolbe's superior but not as a constructive worker; Frankland and Kolbe's synthesis of acetic acid (1846) is one of the most clear-cut achievements in the early history of the development of the doctrine of chemical structure. Kekulé seems never to have grasped its significance and the extent to which it put their work in advance of his.

In his Kekulé memorial lecture (1897), the late Prof. Japp, who was intimately associated with both Frankland and Kekulé, boldly took the valency infant in hand and divided it between the contending parties, assigning the body to Frankland and the head, at most, to Kekulé. His ultimate conclusion was that indicated by Kekulé himself, on the occasion of the great benzene festival in Berlin, Mar. 11, 1890, at which I was present as representative of our Chemical Society. As Kekulé then said, speaking of the contending parties, eventually, "both sides—he at the head of the one, Frankland of the other—saw that they had been striving towards the same goal, although by different routes. They exchanged experiences, each side profited by the experience of the other and with united forces they sailed onward."

This is a charitable and broad point of view to which, unfortunately, our German colleague has not lent himself. He takes no notice of Japp's argument, although fully aware of his lecture. He lays no weight upon Kekulé's considered confession. The chief cause of misunderstanding, we now see, was the uncertainty of atomic weights. The cloud was not dispelled until 1860, when Cannizzaro came forward at Carlsruhe and electrified chemists by proclaiming Avogadro's theorem as a precise physical means of establishing the constants of atomic mass. The congress was Kekulé's work: he had seen the need of a decision.

It is only when obituary notices are to be written, that the difficulty of securing any real picture of a man and his achievements becomes the stark, staring certainty it usually is. Then the lights are over painted and the shadows are usually left out. The *nil nisi* adage has done infinite injury. Later on, when the general historian sets to work, he finds himself without safe material to go upon—so history becomes a polite and perjured fiction. The recent marvellous exhibition of Italian pictures at Burlington House has brought this difficulty to the fore—little is known of most of the painters to give the full and desired clue to their painting. We shall never arrive at a real appreciation of the psychology of the scientific worker until we devise some system of periodically reviewing men's progress; better, perhaps, a scheme whereby the keeping of a real diary, including critical comments by friends, relations and others, be made compulsory. In such a way only will truthful history be written in future. Kekulé set an example in keeping his letters. Some of us who are grown up to old age must bitterly repent that we have not followed Mr. Pepys.

To arrive at a general understanding upon special issues must often be impossible—our minds cannot all grasp all that is involved, even if we grasp the issue at all. It is not that "bowsprit gets mixed with rudder sometimes" but that fiddle cannot play the part of flute. Our discussions are often absurd, for this reason: two minds are not always, indeed seldom, open to the same reason.

I would urge, with Sir Thomas Browne, that "it is the method of charity to suffer without reaction"—that it were time to bury the Kekulé-Kolbe hatchet and give all the workers their due meed of recognition, without reference to any incidental reflections. German chemistry has a great heritage in the two men. Kolbe was especially great as a practical executant guided by acute

theoretical conceptions, to him we owe salicylic acid as a manufactured product Kekulé we can claim as a great intellectual master of his subject—donor of the carbon tetrahedron as well as of the immortal benzene hexagon, both veritable and imperishable foundation stones of the theoretical structure of organic science

His biographer is quite outspoken as to some of the social events in Kekulé's career Marrying in June 1862, when thirty three years old, he lost his wife, within a year, in child birth He thereafter devoted himself to the upbringing of his son, only marrying again in 1876 The choice seems to have been a very unfortunate one, his wife being not only of weak physical stock but, in temperament and outlook, incompatible with a man of his intellectual disposition and habits Three children were born of the marriage but all these died in middle age of tubercular disease The comparative scientific infertility of his later years is easily understood when these distressing facts are known

Prof Anschütz has established a Kekulé museum in the Polytechnic at Darmstadt He tells us, that among its treasures is a complete set of notes of Liebig s lectures taken down by Kekulé, also a similar set by Dr Holzmann of Kekulé's Ghent course These must be priceless historical documents Is it asking too much that they should be reprinted as an Ostwald "Klassiker"?

In fine, we cannot thank our German colleague too heartily for his full and reasoned statement of the case Kekulé v Frankland, Odling and Kolbe being cited as co respondents in support of one or the other side In the interests of historic truth, we have now to submit this to a full Court of Appeal It must be dealt with as a Chancery case of world wide import and the meaning of every word and sentence considered, as well as the conditions of the times to which the issues raised relate The brief is a heavy one and the permission of the Court may well be asked for a postponement of the trial until all the necessary interrogatories have been administered and the evidence marshalled afresh We can in no way admit that a case is established we feel sure that eventually honours will be declared divided The statement is none the less interesting, as a passage in the history of our science Prof Anschutz, all will agree, has laid chemists under a debt beyond repayment, by providing them with an adequate memoir of a great warrior, who will always stand before us carrying as shield the incomparable Hexagon to which we may well add the magic tetrahedron as a quartering

HENRY E ARMSTRONG

World Power and the Power of Man

The Time Journey of Dr Barton an Engineering and Sociological Forecast based on Present Possibilities Edited by John Hodgson Pp viii + 89 + 16 plates (Eggington, Beds John Hodgson, 1929) 3*s* 10*d*

IT has become a platitude to say that modern science has provided man with unlimited power over Nature, but if Nature includes man, the platitude is false Slums, unemployment, starvation, and wars bear ample witness to this We may be able to devise the most cunning calculating machines, we may conquer the sea, the air, and the road at incredible speeds, we may flash messages around the globe, probe the atom, and span the outermost confines of space, we may multiply our productivity a thousand fold, but we have not yet conquered the simple problem of distributing the produce of the earth among its inhabitants Has the world population multiplied so enormously that even with the immensely increased productivity that science has provided, we inhabitants of the globe cannot supply our needs, or are we merely still unscientific fools who have not yet considered the first step towards a rational view of world supply and distribution? The fact is, of course, that we are still so steeped in historical and racial prejudices that we have not yet a glimmering of the historical and racial prejudices we have to overthrow before we can examine this question with scientific detachment

Even with our comparatively new found control over material things we are little more than rampaging savages, tearing minerals from the bowels of the earth and levelling forests in wasteful profligacy, to convert them into machinery and power, without a thought of the morrow We have scarcely given a serious thought towards the control and utilisation of world power

Mr J L Hodgson, the well known engineer, in "The Time Journey of Dr Barton", makes a brave attempt to face these and similar issues The author is clearly not one to be swayed by local prejudices, or to be turned from a grand idea by a mere question of national or international complications If it is necessary, in the interests of world power production, to dam up the Straits of Gibraltar with 500,000 million tons of rubble, clay, masonry, concrete, and rock blasted from the Jebala mountains in Morocco fifty miles away, then dammed up it must be The work of construction may take more than a hundred years, and another six hundred years may be required

to lower the sea level sufficiently by evaporation, but what of that? The great power stations at Gibraltar and Port Said would produce 250 million horse power each, evaporation from the whole basin would provide 600 million horse power, or about three times the world's present estimated available water horse power, while some 60,000 square miles of fertile land would be reclaimed

In order to provide a survey of these problems in sufficient perspective, the author borrows Mr H G Wells's device of a "Time Machine", and projecting Dr Barton 2000 years forward, flies him over the surface of the earth as it is transformed and organised according to the ideas of Mr Hodgson By this means he is enabled to pass in critical review the wastefulness of the present day, and to contrast it with the world as it might be under a rational system of organisation It is an old device, an old dream, but the author with his individual point of view has many penetrating things to say His criticisms are not all new, of course, they have been the concern of socially conscious people for years, but he has succeeded in producing a thought provoking book, and a number of constructive—if grandiose—schemes The idea of straightening the great rivers for power production, altering their courses to transform and deserts into luxuriant and fertile lands, of boring miles into the earth for heat power, and of damming up the Mediterranean Sea, are enchanting dreams for an engineer Meanwhile, we cannot make up our minds on the question of a mere Channel Tunnel

The author is not content, however, with a mere exposition of the power of power He has much to say of our human wastage, useless child bearing and infant mortality, debility from preventable diseases, indulgence in soporific drugs, wars, competition and obstruction in civil life, faulty planning of necessary world routine work, our stupid and obscure money system, restrictions due to language differences, all the criticisms, in fact, that inspire isolated small groups to enthusiastic but impotent reform To most of these he has something new and refreshing to add

Mr Hodgson's attempt to read a lesson in world potentiality, while it is intensely illuminating, does not face the real issue There have not been lacking religious, social, and now scientific enthusiasts to point to a visionary future as a possible present, but inherent in its attainment is always the difficulty of reaching to it As well ask a paralysed thirsty man to reach out for water If we were merely inhabitants of the earth, we might corporately and intelligently avail ourselves, in the most scientific manner, of the world's enormous possibilities, but we are not such idealised beings We are creatures of prejudice, we prefer Oxford to Cambridge, England to Scotland, Britain to France, whites to blacks We have acquired special rights here, and inherited prestige there, which we must not lose, in groups we are morally and racially superior to this one and that, and we have Imperial, national, civic, or parochial 'principles' at stake To the student who, like Mr Hodgson, frames his problem on a world scale, there is no measure for these trivialities His picture is grandiose and alluring But to him who has to handle the problem on a national or local scale, the picture is sordid and cramped We become paralysed spectators We are hungry, but with all the will in the world we cannot eat of the alluring fruits dangled before us H LEVY

North American Dragon-flies

A Handbook of the Dragonflies of North America By Prof James G Needham and Hortense Butler Heywood assisted by Specialists in certain Groups Pp viii + 378 (Springfield, Ill, and Baltimore, Md Charles C Thomas, London Baillière, Tindall and Cox, 1929) 31s 6d net

NEARLY seventy years have elapsed since the last comprehensive publication on North American dragon flies appeared and the number of known species has about doubled itself in the mean time The present volume will be welcomed as one which fills a much needed requirement, since it is not merely a guide to the species found over that continent, but is also a general introduction to the order as a whole Unlike its predecessor, it is not a severely technical work, and it is primarily designed for collectors of these insects and for students of their natural history

Part 1 of the book is introductory and describes the essential facts of the structure and biology of dragon-flies, together with methods of dealing with the rearing of the nymphs, and the collecting of the adult insects The greater part of the text is comprised in Part 2, which is devoted to an account of every species of these insects found in North America Free uses are made of synoptic keys to the families, genera, and species, the nymphal stages being treated similarly wherever possible Each species is further described in detail, its distribution is indicated and notes on its habits, times of appearance, or other special features, are added in a large number of cases Some

of the keys, however, appear to be exceptionally short and brief, and it seems open to doubt whether they are really sufficient for the purpose intended in every case Also, the illustrations, although numerous, are of very mixed character—the venational figures leave little to be desired, but those which portray the genital appendages are somewhat crude and deficient in detail—in some cases it would appear difficult in practice to separate one species from another from the illustrations

Taken as a whole, the book is an excellent one for the needs it is intended to supply, and it is no small achievement to have dealt with a fauna comprising 75 genera and 360 species and describe every one of the latter Over so wide an area as the North American continent there must be many more species yet to be discovered the geographical ranges of the known species are, as yet, but imperfectly mapped, often only one sex has so far been described, but for many species the nymphs still remain unknown To these desiderata may be added the need for life history studies, since they have only been followed completely and accurately in very few dragon flies It is, therefore, within the capacity of every user of this book to contribute something new to the subject, however small or apparently insignificant the facts may be With the present guide at their command, those who observe and collect American dragon flies will acquire renewed stimulus, and their gratitude is due to the authors of this book, and to the specialists who assisted in its production A D I

Our Bookshelf

Grosse Naturforscher eine Geschichte der Naturforschung in Lebensbeschreibung Von Philipp Lenard Pp 324 + 16 Tafeln (München J F Lehmanns Verlag, 1929) 12 gold marks

In his account of the personal history and life work of great men of science, the author has attempted the ambitious task of selecting the most outstanding achievements in scientific thought from the days of Pythagoras to modern times Naturally enough, he has excluded from his survey all living persons, and for this reason he has arbitrarily chosen the end of the War as his time limit The reader is bound to marvel at the thoroughness and patience with which the original records have been searched in the earnest desire to avoid the temptation of following too closely the many standard historical works on the subject In fact, the author claims that credit has sometimes been erroneously given for new lines of thought to those who have merely developed and expanded what was no longer new but had with the lapse of time been overlooked For example, the discovery of the rare gases of the atmosphere, to which merely a passing reference is made, is regarded as the natural development of an early experiment by Cavendish, and the actual discoverer of radium is not named

The book opens with Pythagoras, founder of a great school of morals, to whom is attributed the credit of pointing out the importance of quantitative measurement The daily rotation of the earth, for the recognition of which Galileo had to fight two thousand years later, was also taught Euclid, Archimedes, and Hipparchus, the astronomer, whose accurate observations were chiefly made known through the writings of Ptolemy, complete the list of pioneers of the pre Christian era Then follows a dead period of more than fifteen centuries, in which none of equal eminence is to be found The new era opens with Leonardo da Vinci, the famous painter, who left behind a valuable mass of notes, which reveal his extraordinary genius in no uncertain manner Then follows a brilliant succession of astronomers, mathematicians, physicists, and chemists, among whom we find the names of many eminent Englishmen— Boyle, Newton, Black, Watt, Priestley, Cavendish, Dalton, Davy, Faraday, Kelvin, Maxwell, Crookes, and others Biological science is represented by Darwin, to whom several pages are devoted, and by Mendel

A Course in Physics for Medical and Dental Students By Richard Ablett (Oxford Medical Publications) Pp xviii + 249 (London Oxford University Press, 1930) 8s 6d net

THERE was reviewed in these columns last year a book by Prof Russ on physics for medical students In that book the author stated his aim to be to concentrate on parts of physics of most direct application in medicine This meant cutting down the sections on sound and magnetism to a minimum Mr Ablett in his book, with apparently the same object in view, has omitted these two subjects altogether As he says, he feels that sufficient ground is already covered in these subjects at school and any further work in the subjects would not be commensurate with the value of the applications met with later, at least in comparison with those in other branches of physics

These two aims at departure from the stereotyped form in which physics is presented to the medical student of to-day indicate a genuine desire on the part of at least two teachers to do more for the medical student with physics than has been attempted in the past To the reviewer it seems that Mr Ablett has succeeded extraordinarily well in the task he has set himself In practically every section of the book some space is given to the direct application in medicine of the physical principles enunciated This makes excellent reading, and the student cannot fail to see the significance of the subject in the bigger one of medicine that he is tackling

If, however, these attempts are to be anything more than attempts, some recognition should be given to them, and the only way in which authority can do this is to agree upon a recasting of the syllabus for the pre medical examinations For the furtherance of his plan Mr Ablett is placed at an

advantage in that he is teaching his physics to students whom his department will be examining later on, but it is a very different matter to get these different aspects of physics a definite place in the curriculum of medical schools all over the country The first thing, of course, is to get a responsible body of people to express an opinion as to whether it is desirable, and if it is, then immediate steps should be taken to give effect to responsible opinion

Traité de biocolloïdologie Par W Kopaczewski Tome 1 *Pratique des colloides* Deuxième édition entièrement remaniée et mise à jour Fascicule 1 *Propriétés mécaniques des colloides* Pp xviii + 166 + iv (Paris Gauthier Villars et Cie, 1930) 40 francs

DURING the past eight years the author has produced eight volumes dealing with various branches of colloid science, with catalysis, hydrogen ions, and mineral waters The present treatise appeared first in 1922, but is now being expanded to a series of five volumes, dealing with colloid technique, bio colloids, conditions of equilibrium of bio colloids, the colloidal state and biology, and the colloidal state and medicine, respectively The first section of the first volume, which has now been issued as a separate part, under the general heading of mechanical properties of colloids, covers the preparation and properties of pure water, the preparation of hydrosols and hydrogels, determination of density of liquids, determination of micellar dimensions, diffusion, ultra filtration, dialysis, and the swelling of gels

In the preface to the new edition, the author himself describes the success that has attended his work, explains why his book has been so successful, points out that no similar book exists in scientific literature, and issues a warning as to the treatment that will be meted out to those who quote his work without acknowledging the source from which they have borrowed their material Since the first volume, when complete, will include about 600 pages and is to be followed by four others, it is clear that the literature of 'biocolloidology', like the gels described in the last chapter of the present issue, is likely to undergo considerable swelling in the near future

A Simplified Presentation of Einstein's Unified Field Equations By Prof Tullio Levi Cività Authorized translation by Dr John Dougall Pp 22 (London, Glasgow and Bombay Blackie and Son, Ltd, 1929) 2s net

AT the beginning of 1929, Einstein published his unified field theory of gravitation and electromagnetism, based on the concept of parallelism at a distance with respect to four orthogonal vectors of reference Levi-Cività discards this concept and uses Ricci's coefficients of rotation This is termed a simplified presentation of Einstein's theory, but it really differs from it in one important respect It is perhaps more elegant than Einstein's work, and obtains Maxwell's electromagnetic equations and the gravitational equations of the older relativity theory exactly, whereas Einstein now obtains these only as first order approximations The fact that Einstein's new equations, in their exact form, contain both gravitational and electrical terms in a way that defies separation, however inconvenient it may be mathematically, is yet the most attractive feature from the physical point of view, as it may possibly lead to the discovery of new experimental facts on the interaction of gravitation and electricity Up to the present, in spite of improvements in the mathematical presentation of Einstein's work, little progress has been made on the physical side, and the problem of incorporating the quantum theory with relativity remains still unsolved

H T H P

Differential Geometry of Three Dimensions By Prof C E Weatherburn Vol 2 Pp xii + 239 (Cambridge At the University Press, 1930) 12s 6d net

THE distinctive feature of Prof Weatherburn's treatment is the great use that is made of vector analysis At first sight a page full of terms such as *div*, *rot*, *grad*, and *dyadic* looks rather alarming, and the Clarendon type used for vectors stands out from the ordinary type used for scalars, producing a somewhat unattractive mixture, as if the printing had been done by an unskilled hand However, a careful study will show the advantage of vector methods They are very concise, and yet they emphasise the geometric considerations which are often obscured by the use of co ordinates

The book contains thirteen chapters, the majority based on Prof Weatherburn's own researches Chapters i and v deal with differential invariants, ii, iii, and viii with families of curves on a surface, iv and vi with families of surfaces, vii with dyadics, ix with Levi Cività's parallel displacements, x with projection and allied topics, xi and xii with deformation and flexion, xiii with congruences of curves There are twelve sets of examples, eleven diagrams (we could wish for more), and an index H T H P

The Annual Register a Review of Public Events at Home and Abroad for the Year 1929 Edited by Dr M Epstein Pp xiv + 326 + 164 (London, New York and Toronto Longmans, Green and Co, Ltd, 1930) 30s net

THIS valuable work again contrives to cover a survey of the world's history within the compass of a few hundred pages Its hundred and seventy-first issue speaks for its usefulness Little change is made in the customary arrangements Part I, which constitutes more than half the volume, is devoted to English, Imperial, and foreign history, for this year the sections on India and the Dominions are grouped together Mandated territories are included in the foreign section but the colonies seem to be omitted Part II begins with a chronicle of outstanding events followed by reviews of literature, science, art, finance, and law, and a number of biographies The scientific section has ten pages of an admirable summary of work in the biological and physical sciences Appendices give the text of certain treaties of the year

Letters to the Editor

The Age of *Australopithecus*

THE little fossil ape skull that was found at Taungs five years ago is, in the opinion of many, the most important fossil ever discovered It is manifestly the remains of an anthropoid ape somewhat allied to the chimpanzee and of about the same size But it differs from both it and the gorilla in a large number of characters, and in almost all these characters it resembles man It thus seems highly probable that it is very near to the ape from which man sprang, and possibly a representative of the very genus One difficulty has been our ignorance of the age of the cave deposit The bone breccia found in most caves has proved to be of Pleistocene age and if the Taungs cave is also of this period, then *Australopithecus* would be too recent to be a possible human ancestor, as man is known to have existed in the Pliocene

Dr du Toit and I have independently suggested that the deposit is quite as likely to be Pliocene as Pleistocene but we had very little evidence of the age A couple of months ago Prof Dart kindly allowed me to have for examination a few pieces of bone breccia that had been found in association with the ape, and an examination of this material has resulted in such important new light that a preliminary announcement seems called for

It has been known for some years that remains of an extinct baboon occur in considerable numbers in the deposit, and this has been named by Haughton *Papio Africanus* It is a primitive baboon not very closely allied to any living forms

There are also large numbers of skulls and bones of a Dassie This on examination also proves to be an extinct form, which I am calling *Procavia (Prohyrax) antiqua* It is fairly similar in size to the common Cape hyrax, but the teeth are much more brachyodont

A more startling discovery has been a giant rodent mole rather larger than *Bathyergus*, but more nearly allied to *Georhychus* It has large flat permanent growing molars I am naming it after Prof Dart, *Gypsorhychus darti*

Then we have remains of a small spring hare which is quite a distinct species from the living one This is being called *Pedetes gracilis*

There are portions of the skulls of at least three antelopes One too imperfect for identification is about the size of a reed buck The other two which can be determined are both extinct forms The larger of these two bucks is roughly about the size of an oribi It has a very large antorbital depression, and the orbit is placed farther back than in any living buck of the subfamily Neotraginæ to which it clearly belongs I am calling it *Palæotragiscus longiceps*

The smaller of the two identifiable bucks is allied to the blue buck, but much smaller, and the smallest member of the genus It is being called *Cephalophus parvus*

There are fragmentary remains of a number of other small mammals, and of birds, tortoises, and lizards, beside numerous carapaces and limbs of a fresh water crab (*Potamon* sp)

All the mammals sufficiently preserved to be identifiable prove to belong to extinct species, and the baboon and hyrax are primitive types

A deposit in south west Africa, which is believed by Stromer to be of Miocene age, has yielded remains of a Hyracoid, a spring hare, and a Bathyergid But none of these south west African forms is closely allied to the Taungs animals

As no forms exactly similar to those of this breccia are known from elsewhere, we cannot, of course, determine the age with certainty As, however, all the mammals are extinct forms, the evidence is strongly in favour of the deposit being Pliocene, and I think quite likely it will prove to be Lower Pliocene

Comparison of the Ultracentrifuge Method for Molecular Weight Determination with the Classical Methods *

UP to the present there has been scant possibility for a direct comparison between the ordinary methods for the determination of molecular weights of substances in solution and the recently developed ultracentrifuge method In fact, Adair's refined osmotic pressure measurements on hæmoglobin,[1] giving a value (66,000) that compares favourably with the ultracentrifuge value of 68 000,[2] provided the only independent data It was therefore thought desirable to attempt a comparison on a substance of sufficiently low molecular weight to give fairly trustworthy results with the ordinary methods of boiling point elevation or freezing point lowering

The ultracentrifuge method of determining molecular weights depends in principle upon the analysis of the light absorption of the radial concentration gradient in the solution subjected to a strong centrifugal force In order to obtain satisfactory results for molecules of the order of 1000 in weight, we therefore chose two substances possessing a high light absorption and a high density sodium eosinate and sodium erythrosinate With a centrifugal force of 9000 times gravity the sedimentation equilibria in 0 5 per cent salt free solutions corresponded to molecular weights of 403 and 977 respectively, the boiling point method gave 530 and 601 for the first compound and 622 and 636 for the second

These centrifuge values are only apparent owing to the electrical effect arising from the partial separation of the large dye ions from the small sodium ions, similarly, the boiling point values give only an apparent molecular weight on account of the large ionisation of the sodium dye salts When enough sodium chloride was added to eliminate the electrical potential arising from the partial separation of ions in the centrifuge, both dyes were found to consist in solution of double molecules with two dissociated sodium ions The other two sodium ions are perhaps rendered osmotically inactive by the close proximity of the complex dye group— that is, the Hammersten effect The sodium eosinate consists wholly of double molecules—the value found was 1343, as compared with 1384 for the molecular weight of $(Na_2 \text{ eosinate})_2$— but the sodium erythrosinate has, in addition to double molecules, a small amount of more highly associated material and perhaps some fragments of molecules in solution as well It is not likely that the concentration of sodium chloride used was sufficient to produce any 'salting out' effect, but this point must be studied in more detail

The successful application of the ultracentrifuge method to the study of these dyes enables us to attack the special problems—degree of uniformity, purity,

* Contribution No 33 from the Experimental Station of E I du Pont de Nemours and Company

degree of ionisation, and the like—of the substances of molecular weight of the order of 1000 from two converging angles first, the ordinary methods for relatively simple molecules, and second, the centrifuge method for more complex molecules

In the ordinary methods, the solution must be absolutely free of foreign ions of low molecular weight and the ionisation must be considered in calculating the true molecular weight of the substance in solution On the other hand, it is evident from the results obtained that the centrifuge gives the molecular or ionic weight directly even though foreign ions or impurities are present, that is, if enough electrolyte is added to repress the electrical potential set up by the partial separation of the ions in the centrifuge

A detailed account of this work will be published elsewhere J B NICHOLS

Stability in Soap Films

THE great increase in recent years of knowledge of the specific properties of surface films has naturally made it easier to understand more of the recorded behaviour and stability of Dewar's long lived soap bubbles and films, but among the questions that may still be considered uncertain that of the possible stratification is not the least interesting Recently it has been suggested that stratification in soap films is an abnormal condition, partly because under a certain defined condition a sheet of permanently solid leaflets can be produced

Now it is certain first that the usual limpid grading of the several colour bands down to the universally sharp boundary of the 'black' film is a deception masking the real mechanism When a bubble develops under perfectly quiet conditions of temperature humidity, etc, the colours do not remain graded for long, but separate between numerous boundaries, usually visible to the unaided eye, and often quite as distinct as that defining the 'black' area Several of the Dewar colour photographs show this in part The fully developed appearance is very like stratus clouds at sunset Further, in early stages of development especially, the graded coloured film is invaded by numerous stars, often drawn out by movement into a comet like shape, and always well contrasted in colour from their surroundings, that their boundary tends to the circular shape is evidence of their definite separation from the surrounding film (Fig 1) Even in a film much too thick to show colour, similar behaviour can be detected at glancing incidence

This latter appearance can be induced in greater or less measure over the whole of a quiet bubble by very small departures in the direction of either alkalinity or acidity from the optimum value for the stable bubble This reaction is akin to the well known tumultuous or 'critical' development (but not extending to the black stage) and can be readily seen, for example, by momentarily removing the stopper from an ammonia reagent bottle near to a quietly graded bubble on a ring in the open air, It is reasonable also to suppose that this is a similar occurrence to the experiment of Lyons and Rideal in forming at will a bimolecular from a monomolecular acid film by small increase in alkalinity, and that it is in the same class as the observations recorded in the Dewar papers of the spontaneous change of second order into first order black in dilute 'Plateau' solutions, the deeper black appearing on the uniform greyer black as a slowly growing circle ringed with tiny silvery droplets from the aggregation of the disappearing layer It may be added that this has occurred in a quiet black film formed from ordinary concentrated Plateau solution which is approximately 2½ per cent sodium oleate in 25 per cent glycerin

Here, then, the Perrin and Wells stratifications become revealed as almost certainly pervading the whole film, which appears therefore to persist not merely because of the intrinsic cohesiveness of the several bi or poly molecular strata, but also by means of a powerful but labile attraction between their successive surfaces throughout the film these surfaces being so well ordered in some definite arrangement as to be mutually active The picture agrees with an extension of the McBain diagram with a more extended and more com

FIG 1 Normal thinning of soap films showing separation of various coloured spots

plete orientation beneath the surface layers, and it seems reasonable to suppose that cohesive layers, in whatever position they may be formed, would be as orderly as possible in the absence of disturbance and finally extend to complete lamination in films of reasonable thinness McBain's diagram shows partial bimolecular layers often reduced almost to monomolecular thickness by a sort of alternate lateral surface cohesion or mutual activity of the successive long chain molecules, and indeed such a mesh gives the impression of greater strength and stability than the more commonly depicted monomolecular sheet, unsymmetrical of course on its two faces, and supposedly only so maintained by the anchoring action of the carboxyl radicles presented over one face only

The extended stratified appearance is no doubt presented in large quiet bubbles rather than in flat films on rings of moderate dimensions, because the disturbances from the Gibbs' ring support are more remote in the former case The intensity of formation of the thicker coloured leaflets is not so great as that producing the black or thinner stages So much is evident from the description in the Dewar papers of various forms of black development—from the slow separation and coalescing of tiny black spots throughout a coloured film, to the cataclysmal aggregation of black masses from a thick scarcely coloured liquid sheet up through a whirling delta to the rapidly extending black area 'Spots' and 'black masses' are, however, the very antithesis of what must, on the dimensions of the film itself, appear relatively as deep hollows and abysmal canyons, the black stream, as

it forces its way through, piles up the thick film on each side in a manner almost as miraculous as the passage of the Israelites across the Red Sea ! A very large lowering of surface energy in the production of the black state would explain this

Doubtless, then, the intensity of separation becomes less as the separating layer is greater in thickness Separate coloured discs upon the black area skate about not only without being absorbed, but without even spreading, and show much of the behaviour of impacting bodies, and they can be increased to a thick colourless stream flowing across the black film without altering its character, another evidence of differences of surface energy So also a bubble, partly black, is expanded and contracted only by variation in thickness of the coloured portion, the black area remaining constant despite very large changes of diameter, but coloured areas, although to a less extent, do display mutual repulsion and maintained separation

Such matters of actual observation lead to views on stability that may be epitomised as follows Stability in a soap bubble is possible only where the disruptive action of surface tension is overpowered by structural cohesiveness, surface action however, being vital to ordinary thinning, any local fault or developed weakness in the structure results in instantaneous collapse The protection provided by an enclosure freed from floating solid matter or spray or deleterious volatile material is necessary, but the bubble is likely to be stable only when its composition is maintained sufficiently uniform throughout the thinning process to allow of the production of layers of equal or approximately equal surface activity and therefore cohesion Otherwise too sudden local changes of surface energy will cause rapid sweeping up or local aggregation of these layers, and a closed vessel has the obvious further use of facilitating the desirable uniformity

For the purpose of encouraging simple experimentation it may be added that, so far as the quality of the materials is concerned, it is doubtless true that highly purified oleic acid is advantageous for special observations, but perfect success and stability are readily secured with good oleic acid purified by the old Allen method (warm treatment with successive small proportions of lead oxide, etc) This ensures a sufficient absence of saturated acids, which produce unworkable variations in viscosity, or even, as Lawrence has recently shown, solidifiable stratifications with consequent ' faults ' in film structure

Measurement of Relative Specific Heats of Gases at High Temperatures

IN two recent papers [1] a new method has been described for measuring the specific heats of gases The essential part of the particular form of apparatus described is a calorimeter containing an iron tube, which is heated by an electric current, so as to raise the temperature of its centre some 10° C above that of its ends Two thermojunctions placed symmetrically each side of the centre of the tube, and therefore at points initially at the same temperature, are connected in opposition to a galvanometer It was shown that when a gas flows through the tube, the resulting deflection of the galvanometer is an accurate measure of the heat capacity of the gas Although this method has already been used with success up to temperatures of 600° C by placing a calorimeter of this type in a suitable oven, serious technical difficulties are likely to be encountered at considerably higher temperatures In this letter a modification of the method will be described which is very well suited for the measurement of relative specific heats at high temperatures

A long platinum tube, which in the preliminary experiments to be described had a length of 25 cm. and an external diameter of 1 5 mm, has its ends maintained at room temperature and is heated by passing through it an electric current Except near the ends the tube will have a uniform temperature of, say, 1300° C The distance from the ends at which this uniform temperature is appreciably attained depends on the thermal conductivity of the tube and on the heat loss For the tube used at 1300° C, this length is about 6 cm, leaving the central 13 cm of the tube at a uniform temperature The tube is now cooled (or heated) slightly at its centre, so as to produce a temperature drop (or rise) of, say, 20° C This can be done in many ways, perhaps the simplest being to increase the radiation loss from the centre of the tube by attaching there a small piece of platinum

It has been shown (loc cit) that the heat transfer H between a tube and the gas flowing in it, is given, to a first approximation, by $H=Q\frac{d\theta}{dz}$, where $\frac{d\theta}{dz}$ is the temperature gradient along the tube and where Q is the heat capacity of the gas passing in unit time Thus

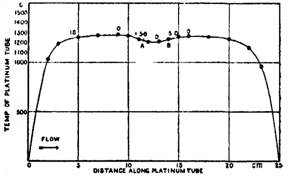

FIG 1

when a gas flows through the platinum tube the temperature distribution will be altered, the parts where the gas is rising in temperature being cooled and vice versa But the temperature of the two uniform temperature parts of the tube will not alter since there $\frac{d\theta}{dz}=0$ Hence the *central* part of the tube, with its temperature dip of 20° C, will have its ' ends ' maintained at the constant temperature of 1300° C It will therefore serve to measure the relative heat capacity of gases between 1280° C and 1300° C

The essential feature of this method is the existence of the two uniform temperature parts of the tube separating the shallow central dip from the steep gradients near the ends These parts serve to make the temperature distribution near the centre quite independent of what happens near the ends, even when a gas is flowing in the tube This method therefore enables one to measure the relative specific heats of gases over, say, a 20° C range at 1300° C, with an apparatus in which the only part heated at all is a narrow platinum tube

A convenient method of measuring the temperature changes due to the flow is to project images of two short lengths of the tube, situated symmetrically at A and B on each side of the central dip, on to two thermopiles These are connected in opposition to a galvanometer and the deflection of this, due to a gas flowing in the tube, will be proportional to the flow

rate multiplied by the mean specific heat between 1280° and 1300° C. The curve in Fig. 1 shows the temperature distribution, measured with an optical pyrometer, obtained in some preliminary experiments. The numbers against the curve are the measured temperature changes in degrees centigrade due to a flow of air from left to right. In spite of the large cooling (40° C.) near the end, the temperatures of the uniform parts are unchanged. This gives experimental demonstration of the practicability of the method. The actual dip shown of 60° C. and the flow rate of 70 c.c. per minute are both too large for actual determination of specific heats.

By using platinum iridium tubes the method should be feasible up to 2100° C., and with certain gases in tungsten or molybdenum tubes up to even higher temperatures.

Mortality amongst Plants and its Bearing on Natural Selection

IT is a familiar fact that the majority of plants produce a vastly larger number of offspring than can possibly survive, but unfortunately exact quantitative observations respecting their mortality is meagre in the extreme.

In the course of collecting data for ecological purposes, certain facts have come to light regarding the death of young plants which, if typical, would appear to be of fundamental importance in any estimate of the incidence and intensity of natural selection. By briefly indicating here the nature of these preliminary observations, it is hoped that other investigators may be induced to record their experience and to collect data of a similar character so that it may be possible to judge as to how general is the phenomenon in question.

A typical example is furnished by *Silene conica* L. This plant, which is one of the steppe species in the flora of Great Britain, behaves as a winter annual. The seedlings germinate in September, and on a marked quadrat there were present, soon after germination, no less than 175 seedlings per square decimetre. By Nov. 23, whilst still in the cotyledonary stage, the number of seedlings had become reduced to 110, whilst by Jan. 31 only nine survived. There is thus not only a very high mortality amounting to nearly 95 per cent, but also the important fact is that this mortality was entirely confined to the seedling stages. All the mortality occurred prior to the formation of the second pair of foliage leaves, and all the nine survivors will clearly attain the flowering condition. A large plant of *Verbascum Thapsus* L. produced several hundred thousand seedlings, of which, however, all but 108 died during the first six months. All the survivors which attained the rosette stage flowered and produced seeds. Similarly, the winter annual *Ranunculus parviflorus* L. in Cornwall produces large numbers of viable seeds, and sometimes the seedlings are seen in great abundance, but in an experience of this species extending over several years close observation both in culture and in the feral state, it is evident that practically the whole mortality occurs prior to the rosette phase and that almost all the individuals which attain this condition produce flowers and fruits.

Observations on the spring germinating *Helleborus viridis* L. showed a mortality of more than 50 per cent in the first month, and observations on *Cochlearia danica*, *Dianthus prolifer*, and other species would appear to warrant the conclusion that, in these plants at least, the mortality and therefore the operation of natural selection is almost entirely confined to the juvenile stages of development. Observations on seedlings of *Fagus sylvatica* after the 'mast' year of 1922 indicate that this is true also of arboreal species. In the case of two species of *Silene*, namely, *Silene conica* and *Silene anglica*, the mortality in the plants under observation, took place at so early a stage that, if growing intermingled, the seedlings could only have been distinguished if at all with the greatest difficulty. Of the plants which survive to the stage when the distinctive external specific and generic characters appear, almost all produce flowers and fruit and probably yield offspring.

Field observations suggest that the incidence of mortality described may well be of general occurrence. Certainly in the instances cited it would appear that the adult characters, apart from those concerned with efficient pollination and seed dispersal, can play no direct part in determining survival, but that in so far as survival is dependent upon the structure and physiology of the species, it is the characters of the juvenile, not the adult, which are important. When mortality does occur in the more adult phases of development, it is generally the result of catastrophic causes which destroy the fit and unfit with equal impartiality.

If the adult characters upon which we rely for taxonomic distinctions, apart from the exceptions mentioned, owe anything to natural selection, it must be not because of their external manifestations but because they are the inevitable consequence of those characters, probably internal, which determine survival in the juvenile stages. Any selection which might occur in the adult phase will clearly be connected with the direct production of viable seeds by individuals and not by a selection amongst progeny.

The actual selection amongst the progeny of individuals, the classical *modus operandi* of natural selection, would then appear to occur almost entirely in just those phases of development which show the greatest similarity between species, those phases which show the least divergence of morphological type. If then natural selection be an important factor, the uniformity of the juvenile morphology and the great diversity of that of the adult present natural selection in the guise of a factor tending towards homogeneity rather than towards the divergence of type which it has usually been supposed to bring about.

Methyl Glyoxal as an Intermediary in Fermentation

WHILST the earlier work on fermentation, especially Prof. Neuberg's investigation of the *second form of fermentation*, rendered the participation of methyl glyoxal as an intermediary stage probable, proof that methyl glyoxal is formed by systems capable of fermenting or glycolysing sugar has been obtained by the recent work of Toenniessen and Fischer (*Zeits. physiol. Chem.*, **161**, 254), Ariyama (*Jour. Biol. Chem.*, **77**, 395), and especially by Neuberg and Kobel and various collaborators (*Biochem. Zeits.*, **203**, 463, and later papers). The latter workers conclude that methyl glyoxal is only dismuted or fermented in presence of cozymase, whilst its formation takes place also in absence of cozymase if hexose phosphate is used as the substance of origin.

Its identification as a substance produced *in vivo*

raises again the question as to why methyl glyoxal is not fermented when added to yeast or yeast preparations With glycolytic systems, no such difficulty arises, as the glyoxalase of Dakin and Dudley (Neuberg's keto aldehyde mutase) provides an enzyme system capable of acting on added glyoxals Prof Neuberg has suggested as a hypothesis that methyl glyoxal, in order to be fermented, has to be present in one of the many tautomeric forms theoretically possible for this substance, perhaps some enol or ring form

The first transformation that methyl glyoxal undergoes in fermentation, its oxidation to pyruvic acid, appears to be a dismutation, in which acetaldehyde is simultaneously reduced to alcohol It is not possible on the present evidence to decide whether an aldehyde mutase of the type discovered by Parnas and by Battelli and Stern is responsible for this transformation , a close analogy is, however, suggested by recent work of the Euler school (particularly Euler and Myrbäck (*Zeits physiol Chem* , **165**, 28) which shows that the necessity for cozymase is characteristic for aldehyde dismutations Since dismutation is typical for substances possessing a free - CHO group, and independent of the structure of the rest of the molecule, one would expect methyl glyoxal to be fermented in its - CO - CHO form and not in some enolic modification It is interesting that according to Ariyama (*Jour Biol Chem* , **77**, 359) the lactic acid formed from methyl glyoxal by liver extract accounts quantitatively for the methyl glyoxal disappearing , that is, all methyl glyoxal is destroyed by internal dismutation, none undergoing the ordinary aldehyde mutation to CH_3 CO COOH and CH_3 CO CH_2OH

Work by me (*Biochem Jour* , in the press) has shown that phenyl glyoxal, though reacting in a peculiar way with di-amino acids, does not show the reaction with mono amino acids typical for the - CHO group It is known that phenyl glyoxal forms a stable hydrate, and this peculiarity might explain its refusal to behave as an aldehyde, which is also shown by the sluggish way in which it reduces Fehling's solution According to unpublished work by Mr Pirie, chloralhydrate also does not react with mono amino acids Enolisation might also explain this peculiarity of phenyl glyoxal, but the readiness with which it forms osazones, glyoxalins, and so on, shows that if enolisation does take place in solution, it must be easily reversible Methyl glyoxal resembles phenyl glyoxal in its chemical reactions and in its behaviour towards glyoxalase It also forms a stable hydrate (as shown, for example, by its great heat of solution) and it seems probable that methyl glyoxal is not fermented, because, in solution, it does not possess a free - CHO group, One would then assume that methyl glyoxal formed *in vivo* exists at first in the - CO CHO form, and is normally oxidised before it has time to take up water Any methyl glyoxal escaping and passing into the inactive form would presumably be removed by glyoxalase

The question remains as to why the internal dismutation under the action of glyoxalase is not similarly inhibited It must be kept in mind that the above argument only applies to reactions which require a free - CHO group Since in the action of glyoxalase both carbonyl groups of the glyoxal are concerned, it seems possible that the point of attack of the enzyme is at the keto group The examples of chloralhydrate and mesoxalic acid show that stable hydration of a carbonyl group is dependent upon the neighbourhood of strongly negative groupings , in glyoxals the keto group is responsible for the untypical behaviour of the adjoining - CHO Hence reduction of the - CO - to - CH OH - group, or even the reaction of the - CO - group with the combining group of the enzyme, might enable the terminal carbonyl to react as a normal aldehyde group

Quantitative Analysis by X-Rays

No doubt it is at present true that X ray analysis is more sensitive in detecting a trace of an element of high atomic number dispersed in an element of lower atomic number than it is in the reverse case For that and other reasons given by Prof Hevesy (Nature, May 24, p 776), the sensitiveness is variable As the result of experience gained with non metallic substances, the sensitiveness was stated in 1925 to be roughly 0 1 per cent, and we assumed that would be true for metals On making careful tests, in which we had the assistance of chemists experienced in the requisite analysis, the method was found to be more sensitive than that for all impurities in zinc of higher atomic number than chromium Evidence is given (see Eddy, Turner, and Laby, *Proc Roy Soc* , **124**, p 163 , 1929) that the elements 24 Cr, 25 Mn, 26 Fe, 27 Co, 29 Cu, of atomic number less than 30, as well as nine elements of atomic number greater than 30, can be detected in 30 Zn, although none, it is believed, was present to more than about 0 0005 per cent, and one, 33 As, gave its $K\alpha_2$ (and probably its $K\alpha_1$) lines well enough to be measurable to 1 X U , when present by chemical analysis to less than 0 00001 per cent Thus evidence is given in ths paper quoted that the *K* X ray spectrum of an element present to less than 0 0001 per cent in a metal can be photographed Prof Hevesy disagrees with this statement It should be admitted that up to some months ago we had not obtained that sensitiveness when using non metals, but there appears to be no theoretical reason why the technical difficulties met with should not be overcome Has Prof Hevesy evidence that ths sensitiveness mentioned cannot be obtained with a metal ?

Within the limits of space allowable it is not possible to discuss here what Prof Hevesy writes with reference to quantitative analysis more than to emphasise that Dr Eddy and I did not use a reference method in most of the experiments described in *Proc Roy Soc* , **127**, p 20 , 1930 , that is, in calculating the composition of an alloy, no use is made of an alloy of known composition Chemical analysis (or synthesis) was only used to verify the results so calculated The assumption made and verified is "that the ratio of the number of atoms of two elements in an alloy of metals of nearly equal atomic number is equal to the ratio of the intensities of the corresponding lines (say the $K\alpha_1$ lines) in the spectra of the elements provided the lines are excited under equivalent conditions" We believe that this principle, and the method which has been worked out to apply it, will prove of value in atomic analysis by X ray spectroscopy, and make it less empirical than it has been, although it is obvious there is considerable scope for improvement in that respect This advance should be attainable by a further study of the physical phenomena involved

X-ray analysis is being applied much more than might be inferred from the literature of this subject In our experience it is more readily applied to the atomic analysis of metallic than non metallic substances, which means it is more immediately susceptible of application in metallurgy than in mineralogy, although Profs Hevesy and Coster and others have of course obtained most valuable results in the latter field

Early Chinese Rice

AN unusually detailed account of the discovery and utilisation of a 'sport' occurs on page 470 of the 1859 edition of an English translation of "The Chinese Empire," by Monsieur Huc. The account may be of interest to agriculturists and geneticists. The book is not often met with, and indeed I have had no opportunity of consulting the French original.

'I was walking,' says the Emperor Khang hi, 'on the first day of the sixth moon, in some fields where rice was sown, which was not expected to yield its harvest until the ninth. I happened to notice a rice plant that had already come into ear; it rose above all the rest, and was already ripe. I had it gathered and brought to me: the grain was very fine and full, and I was induced to keep it for an experiment, and see whether it would on the following year retain this precocity, and in fact it did. All the plants that proceeded from it came into ear before the ordinary time, and yielded their harvest in the sixth moon. Every year has multiplied the produce of the preceding, and now for thirty years it has been the rice served on my table. The grain is long, and of a rather reddish colour, but of a sweet perfume, and very pleasant flavour. It has been named *ya mi*, or 'Imperial rice', because it was in my gardens that it was first cultivated. It is the only kind that can ripen north of the Great Wall, where the cold begins very early, and ends very late, but in the provinces of the south, where the climate is milder, and the soil more fertile, it is easy to obtain two harvests a year from it.'

M. Huc adds that this rice was introduced into Manchuria, and that it succeeds admirably in dry countries, having no need of perpetual irrigation. He thought it would certainly prosper in France, but although he sent several samples to that country he never heard that any experiment was tried with it.

Two French books allude somewhat vaguely to this rice. "Le Rapport sur les Céréales: Exposition Universelle" (Paris, 1878), mentions the above story and offers the alternative name *riz precoce*. 'Les Plantes de grande culture' (Paris, 1893) says that there appears to be a variety of rice in China which completes its growth in less than three months.

The variety is probably identical with the *yu mi* (*Oryza communis pyrocarpa* Al.) which is the only variety specifically attributed to China by M. A. Carleton ("The Small Grains", New York, 1916).

The emperor Khang hi reigned from 1662 until 1723.

Raman Spectra of Crystalline Nitrates

IN a communication to NATURE of Mar. 22, p. 463, P. Krishnamurti describes some results of his experiments with powdered crystals. In a paper sent two weeks ago to the *Annalen der Physik* I have given the results of my measurements on much the same subject. By suspending the crystal powder in a liquid of suitable refractive index, and using suitable light filters, I obtained the Raman spectrum of such intensity that a spectrograph with large dispersion and very narrow slit could be employed.

Like Krishnamurti, I found a displacement of the inactive NO_3' frequency depending on the kation, and also a new remarkable difference between the anhydrous crystals and the hydrates. The frequency differences of the inactive Raman frequency of the NO_3' ion are as follows: (1) monovalent salts: lithium (anh.), 1086, lithium (hydr. $\frac{1}{2}H_2O$), 1073, lithium (hydr. $3H_2O$), 1055·5, sodium (anh.), 1067·5, potassium (anh.) 1048·4, silver (anh.), 1045·0. (2) bivalent salts: calcium (anh.) 1064·3, calcium (hydr. $4H_2O$) 1044·6, strontium (anh.), 1054·4, copper (hydr. $6H_2O$), 1052·9, copper (hydr. $9H_2O$) 1044·4, barium (anh.) 1046·5, lead (anh.), 1045·0.

Some of the wave numbers are in accordance with the data given by Krishnamurti.

Furthermore, in solutions of the nitrates, I found a variation of the NO_3' frequency with the concentration; for example, for a solution of 10 mol. $NaNO_3$ in a litre of water $\Delta\nu = 1049\cdot8$, and for a 3 mol. solution $\Delta\nu = 1047\cdot2$. For a 14 mol. solution of $LiNO_3$ the Raman difference was $\Delta\nu = 1050\cdot3$, for a 0·5 mol. solution $\Delta\nu = 1046\cdot0$.

Effect of Direct Current on the Frequency of Sonometer Wire

THE maintenance of oscillations of a sonometer wire by the passage of an alternating current through it has been studied in detail by Krishnaiyer and others (*Phil. Mag.*, 1922, etc.). If, however, direct current of the value of about an ampere be passed through the wire, it is found that the frequency of the oscillations, for a fixed position of the two sonometer bridges, is slightly lower than what it is when no current is passing. This effect is best observed by tuning the sonometer with an electrically excited fork placed on the sonometer board. When the wire is tuned to this frequency it begins to vibrate with a large amplitude. These vibrations are observed with a low power microscope. If the direct current be now passed through the wire, the amplitude of the vibrations is immediately reduced, and can be restored again to its original strength by shortening a little the length of the wire between the bridges.

We have verified that this lowering in frequency is not due to the heating effect of the current and is also not a magnetic effect. This effect can also be observed with an ordinary tuning fork and wires of any material.

The quantitative measurements and other interesting results will be published elsewhere.

Band Spectra of Copper Oxide

EDER and Valenta in 1911 had observed some of the bands of copper oxide in the flame spectra of all copper salts. Hertenstein observed them in the flame of the arc in air in 1912. R. S. Mulliken (*Phys. Rev.*, 26, 4, 1925) also noticed them while working on the spectrum of CuI as excited by active nitrogen. They would appear better by a small leakage of air into the halide vapour, or the presence of a little oxygen in the nitrogen used. I have obtained these bands by arcing between copper electrodes in an atmosphere of oxygen. They are degraded towards the red and occur in pairs, of which the shorter wave length component is relatively weak. Their rotational structure reveals that the system is due probably to a $^2\Sigma \rightarrow {}^2\Sigma$ transition. The frequencies of vibration for infinitesimal amplitude are found to be approximately 620 cm.$^{-1}$ and 345 cm.$^{-1}$ for the final and initial states respectively. A detailed investigation will be published elsewhere.

New Light on Vision *

By Prof G ELLIOT SMITH, F R S

MAN alone among living creatures really sees the world in the sense that we usually associate with the verb 'to see' The apes and monkeys are provided with eyes which are closely similar in structure to those of man and on the functional side are perhaps equally efficient dioptric instruments Man's comprehension of what he sees, however, and his understanding of the world of things and actions revealed by his powers of visual discrimination, clearly transcend those of the apes, to which we have no reason to attribute the human quality of understanding what is revealed by sight, of appreciation of beauty, and the subtler forms of actions such as facial expression, or of possessing the initiative and skill that result from the wider vision

Investigation of the comparative anatomy of the brain reveals the fact that within the natural order of mammals (Primates), to which man belongs, the cerebral connexions of the optic tracts have been so profoundly revolutionised that what is virtually a new instrument of vision has been evolved The progressive cultivation of this 'new vision' (see NATURE, April 28, 1928, p 680), eventually led to the emergence of those profound changes in the whole organism which transformed an ape into a human being and conferred upon him the distinctive attributes of mind and skill which are the outstanding tokens of his humanity

The factors involved in the making of the mind fall into several distinct phases The acquisition of definite representation for touch, vision and hearing in a newly evolved area (neopallium) of the cerebral hemisphere was responsible for the emergence of mammals It conferred upon vision not only the possibility of closer integration with other kinds of sensory experience, but also a greater influence in the conscious control of behaviour The birth of a new cortex created a new type of animal profoundly different in every part of its organism and especially in its potentialities In particular the evolution of the neopallium involved the transference to the cerebral hemisphere of the control of voluntary movements and that led to far reaching changes in the parts of the brain and spinal cord concerned with muscular activities The new cortex established direct connexion with the spinal cord, new links with the cerebellum which provoked the evolution of a new element in that organ, and corresponding transformations of the cerebral and cerebellar connexions with all other parts of the central nervous system involved in the control and regulation of movement This remaking of the brain involved the usurpation by the new cortex of many of the functions of the midbrain

The next phase is displayed in the Primates, in which the increasing dominance of vision accentuated the process of transference to the neopallium of the control of movement The increasing concentration of visual functions in the cerebral cortex conferred upon vision a fuller participation not merely in the affairs of conscious life but also in the regulation of motor behaviour, and integrated visual, tactile and motor experience with the kinæsthetic products of the animal's own movements, the consciousness of the postures and actions of its own body The cortex came to play a part

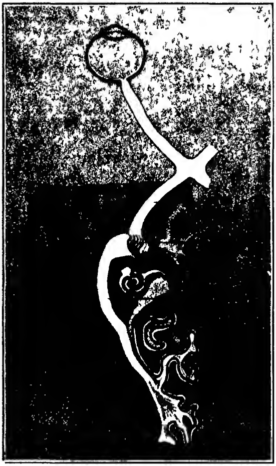

FIG 1

in the control of posture, and this conscious activity eventually conferred upon man not only the erect attitude, but also that intimate integration of skill of hand and eye with the no less important factors we call balance, poise, and rhythm, which with perfection of timing are the essential elements in dexterity

The nervous system was first called into being to facilitate the performance of rapid and precise movements In the direction of these activities an important part has always been played by the eyes Long before they were capable of true vision, such

* Friday evening discourse delivered at the Royal Institution on Mar 14

as the appreciation of images, they were instruments for recording movement in the outside world, and for guiding the animal's own movements Throughout the whole of its subsequent history the refinement of muscular skill has been intimately associated with the progressive modification of the nervous system In its highest manifestation the making of the mind was in large measure due to manual dexterity, the exploration of space with hand and eye and the integration of the knowledge of the world acquired by vision with the intimate personal experience of the movements of our joints

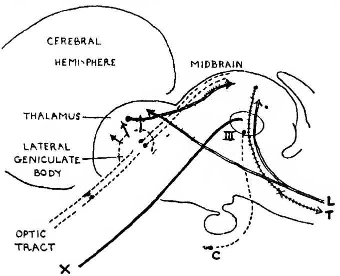

FIG 2

The comparative anatomy of the brain reveals the fact that the progressive development of vision is strictly conditioned by the ability of the hands to be used as skilled instruments It seems that manual dexterity is an implicit condition for the attainment of biological usefulness for the refinement of visual discrimination Vision could not have extended the range of its powers and influence in the Primates if their hands had not escaped the specialisation which in other mammals restricted their power of adaptation

The integration of vision and muscular skill is a complex process The heightened powers of vision provide direction for the acquisition of skill—and the cultivation of skill involves not the hands only, but also the whole body, which is essential for the maintenance of the appropriate posture as well as for the performance of movements that contribute to the successful action of the part, such as the hand, upon which the visual attention is fixed This participation of the whole organism in any act of skill contributes (in some way that we do not understand) to the development of the intricate co ordinations involved in the conjugate movements of the eyes, which in mammals are the essential preparation for the attainment of the fullest cultivation of binocular vision, the development of a macula and fovea, and the ability to see stereoscopically and so add a third dimension to spatial discrimination In addition the proprioceptive impulses from the eye muscles, as well as from the muscles and joints involved in any movement, add their quota to the integration and link the process of spatial appreciation with the personality of the individual This coherence between vision and skill is the essential mechanism for the making of mind and for giving it its distinctive individuality as an intimate part of the personality The practice of manipulation to satisfy visual curiosity which is aroused in its most intense form when the macula is developed, necessarily led to the cultivation of tactile discrimination and stereognosis Visual perception and conception are products of the integration of these factors with vision and as the result the progressive evolution of intelligence

Bearing in mind these considerations the facts of the comparative anatomy of the brain take on a new significance, and in turn features which hitherto have been overlooked can be detected in the brain when the fuller understanding of its working suggests the search for them

In the human brain (Fig 1) the fibres of the optic tract end for the most part (probably not less than 95 per cent) in the lateral geniculate body, where they transfer the impulses coming from the eyes to a new tract of fibres, the optic radiation, which carry them to the visual receptive area now commonly known as the 'area striata' (*Proc Roy Soc*, p 62 1904) This almost exclusively cortical connexion of the pathway leading from the eyes is a token of the fact that in man vision is brought into the full light of consciousness It had lost

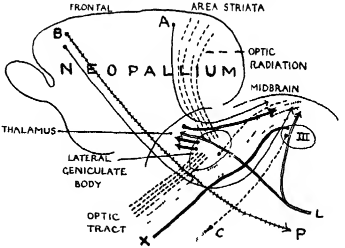

FIG 3

most of those automatic and unconscious photo static influences that are so obtrusive in most other living creatures Vision is the foundation of intelligence and the chief source of our knowledge

This distinction can be graphically displayed by means of three diagrams In the reptilian ancestor of mammals (Fig 2) the optic tract, in spite of the wide currency of Monakow's diagram, does not establish any connexion with the cerebral cortex Most of its fibres end in the midbrain, from which tracts (T) proceed to the motor nuclei in the brain and spinal cord In addition to this connexion, which automatically directs the movements of the animal, there is also a group of fibres (X), which forms part of the light reflex mechanism, using the oculomotor nucleus (III) and the ciliary ganglion (C) to influence the iris and the size of the pupil

Most of the fibres of the optic tract are functionally related to these unconscious activities The number of fibres concerned with the conscious awareness of vision is small They pass to the lateral geniculate body and from it to the thalamus

In mammals (Fig 3) the lateral geniculate body receives a larger proportion of the fibres of the optic tract and transmits some of the impulses (by means of the optic radiation) to the newly developed cortical area, neopallium, which affords a representation of vision (area striata) in the cerebral hemisphere The transference to cortical control of functions previously performed by the midbrain necessitates the establishment of new connexions between the cerebral cortex and the midbrain, both (A) from the receptive visual area and (B) from the area which controls voluntary movements For vision and movement are intimately interrelated In addition, the assumption by the neopallium of the control of the movements of the whole body leads to a profound revolution in all the motor mechanisms in the brain and provides the visual area with opportunity to exercise a wider influence on behaviour

In man (Fig 4) all the midbrain connexions shown in Fig 2 have been lost, excepting only the light reflex arrangements (X) The visual pathway leads almost exclusively to the cerebral cortex, and more than half its fibres (M and M^1) are new elements coming from the macula lutea of the retina Only the monkeys, apes, and men among mammals have a macula and enjoy macular vision The development of this sensitive spot on the retina was not evolved until the axes of the eyes were altered to permit them to look forward and their visual fields to overlap A very complex and precise correlation between the movements of the two eyes is required (conjugate movements) to bring the two images of an object with certainty upon certain determined areas in the two retinæ These areas become the maculæ, the instruments which confer on vision greater powers of resolution and discrimination The development of macular vision led to the progressive transformation of the brain and eventually to the making of the human mind It conferred not only the ability to discriminate between the details of form, texture, and colour, but also led to an enhancement of the knowledge which became accessible to a mind intent upon satisfying the curiosity awakened by such new revelations

Binocular vision enriched by macular efficiency provided the conditions which made possible the attainment of stereoscopic powers, the conscious appreciation of a third dimension in space, the recognition of solidity and perspective A vision of the world was thus revealed to man, with an appreciation of form, colour, size, and space, and a fuller understanding of distance and movement The most significant enrichment of the sensory basis of the mind is conferred by the macula To paraphrase the account given by the late Dr Henry Watt, it ' refines and distinguishes positions and forms, and, aided by the more precise accommodation which becomes evolved in association with it, it sharpens the objects of attention and dissipates the rest " "Stereoscopy adds a new character to a

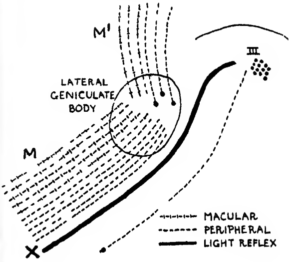

FIG 4

group of forms that may persist for indefinite periods of observation , delicate skin gives greater sensitivity to variations of pressure, and the prehensile hand implies a very great refinement in the positions and forms of the derived articular sense In the hand this becomes a fine mobile tridimensional sense which, like the stereoscopic eye, can go round and through things, so almost isolating them from their surroundings "

When in response to the visual curiosity excited by the new vision of the forms, textures, and colours of objects, the hand, under the guidance of the eyes, examines these objects, and explores their positions in space, not only is tactile information added to visual knowledge and integrated with it, but also the impulses from the joints, muscles, tendons, and in fact from the whole body, recording the effects upon the organism of the accomplishment of the action, are added to the visual, tactile, and motor sources of knowledge Hence, as Dr Watt expresses it, " the articular sense is the conscious correlate of action and of the individual's share in

his experiences " Thus " action enters into the data of sense to integrate with it and so build up psychical mind stuff "

The consciousness of action makes possible ' the integrations of percept and probably of concept that are the beginnings of intellect " It adds the essential personal element in the process of inter action of mind and mechanism, and the interpretation of the means whereby motor skill creates mind For " the first purpose of the mind is to serve the ends of action It is not merely a speculative instrument given to man that he may form for himself a disinterested knowledge of the world, create and enjoy works of art, and plan an elysium of happiness and love " It is primarily a means for seeking actively, under the guidance of attention and interest, the objects of its own desire, and for expressing in movement and other forms of behaviour the satisfaction of the impelling appetites Vision and touch are closely integrated with movements and feelings and the affective results of such expressions of the mind's searching for satisfaction

This brings us back once more to the essential fact one is trying to make clear in this discourse Man's intellectual pre eminence is based primarily on the evolution of macular vision in a Primate with adaptable hands which attained the erect attitude when the cerebral cortex under the conscious influence of vision came to control and regulate posture The profound and widespread effects of this revolution upon the structure and functions of every part of the brain—cerebral hemisphere, cerebellum, red nucleus, substantia nigra, corpus

FIG 5

striatum, midbrain, and hindbrain—will not be discussed in this discourse But attention must be directed to some of the obtrusive expressions of this new vision in the anatomy of the optic parts of the human brain

The development of the macula was responsible for adding to the optic nerves and tracts as many new fibres (Fig 4) as the whole of the rest of the retina (peripheral) supplies In the lateral geniculate body a new receptive nucleus of corresponding dimensions is provided to transmit macular impulses to the cerebral cortex

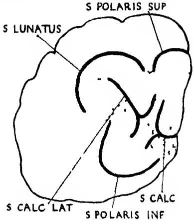

FIG 6

For many years neurologists have been speculating on the nature of the representation of the macula in the cerebral cortex During the War, Henschen's idea of the ' cortical retina ' was revised and corrected by the observations made upon wounded soldiers by Sir William Lister, Dr Gordon Homes, and many other physicians

Recently (1928 and 1929) Prof B Brouwer and his collaborators, Drs Van Heuven and Biemond, in Amsterdam, have introduced a new precision into the cortical localisation of the macula in monkeys Studying preparations of the human brain in the light of their truly epoch making investigations, one was able to detect with the naked eye a sudden change in the texture of the area striata at the place corresponding morphologically to where in monkeys Prof Brouwer and his colleagues located the boundary between the peripheral and macular territories

A drawing of the photograph (the negative) of a horizontal section through the posterior pole of a human cerebral hemisphere is reproduced in Fig 5 The area striata, distinguished by the presence of an intracortical black line, is seen to undergo a sudden change in character as the peripheral part (*P*) on the medial surface is traced backward At the point marked by the white arrow the thickness of the black line is reduced and the pale band on its inner side disappears The macular cortex begins at this place and extends around the pole on to the lateral surface of the hemisphere to end (at *M*) at the lip of a deep furrow (lunate sulcus) As this lateral part of the area striata is much broader than the medial part (*P*) exact measurements reveal the fact that the macular part is at least as extensive as the whole peripheral part

It is possible also to identify the macular part of the area striata in many human brains by simple observation of the morphological features of the surface of the cerebral hemisphere Looking at the

posterior aspect of the hemisphere (Fig 6 represents the pole of the left hemisphere) three semilunar sulci—lunatus, polaris superior, and polaris inferior—may often be seen arranged in a trefoil or shamrock leaf pattern (grouped around the calcarine sulci in the axis of the area striata) The rapid expansion of the lateral part of the area striata to afford cortical representation of the macula is responsible for the formation of opercula bounded by these three semilunar sulci Hence the presence of this cortical shamrock pattern affords definite evidence of the position and extent of the macular area It is so situated in relation to the other cortical areas as easily to be linked up with them in the functions of wider vision, which involve the activities of the cerebral hemisphere as a whole—the process of mind building upon the foundation of macular vision

It is a matter of such vital importance not to overlook the part played by action in mind making that the argument may be emphasised once more, When under the guidance of vision some delicate manipulation is performed, in addition to the success or failure of the mechanical operation, and the emotions of satisfaction or disgust which the results of the attempt and the attendant circumstances excite, the action itself starts a series of impulses from the joints, muscles, tendons and from other parts of the body, which integrate the whole process with the intimate texture of the individual's consciousness and personality The appetites and feelings which prompt the action, no less than the discriminative experience and knowledge which play their part in determining whether it is worth doing and how to do it, become associated with the activities of the whole organism during the progress of the movement It is no longer a mere matter of muscular contraction under visual control, but a complex process of integration of experience and of creating understanding and intellect

Canadian Hydro-Electric Power Development during 1929

By Dr Brysson Cunningham

THE recent issue of two reports[1] by the Canadian Government Water Power and Reclamation Service enables a survey to be made of the expansion which has taken place during the twelve months ended Dec 31 last in the development of hydro electric power in the Dominion The review made in NATURE of July 27 last year, on the statistics then available, showed a very striking and rapid rate of progress This progress has been substantially maintained and important activities are reported from practically every province The total capacity of new installations brought into operation during 1929 amounts in round figures to 378,000 horse power, bringing the aggregate for the whole Dominion to 5,727,162 horse power, as compared with 550,000 h p and 5,349,232 h p respectively, for the year 1928

Table 1 shows the available and developed water power of Canada as determined to Jan 1, 1930 The available power is scheduled in columns 2 and 3 under two heads according to the period of availability These figures are based on a computation of data relating to rapids, falls, and power sites generally, of which the actual fall or the possible head of concentration is definitely known, or, at least, well established There are many other rapids and falls of greater or less capacity scattered up and down the country which are not yet included in the register and can only become available for tabulation when the necessary survey work has been undertaken and completed This is particularly the case in the northern parts of the Dominion, where much exploration remains to be done Moreover, there are possibilities of power concentration on rivers and streams of gradual gradient which have not been taken into account, except at such selected points as have been the objects of actual study and observation Altogether, as a record of potential resources, the figures in columns 2 and 3 may be looked upon as minimum values Indeed, the basis of valuation itself is appreciably below the standard of development obtained in cases of actual installation by so much as 30 per cent If the necessary correction be applied, it will be found that the present recorded water power resources of the Dominion will permit of turbine installations aggregating about 43,700,000 horse power

TABLE 1—AVAILABLE AND DEVELOPED WATER POWER IN CANADA, JAN 1, 1930

Province	Available 24 hour power at 80 per cent efficiency		Turbine Installation (h p)
	At Ordinary Min Flow (h p)	At Ordinary Six Months Flow (h p)	
British Columbia	1 931 000	5,103 500	559 792
Alberta	390 000	1 049 500	70 532
Saskatchewan	542 000	1 082,000	35
Manitoba	3 309 000	5,344,500	311,925
Ontario	5 330,000	6,940,000	1,952 055
Quebec	8 459,000	13,064 000	2 595,430
New Brunswick	68 600	169,100	112 631
Nova Scotia	20 800	128,300	109,124
Prince Edward Island	3,000	5,300	2 439
Yukon and Northwest Terr	294,000	731,000	13 199
Canada	20,347,400	33,617,200	5 727,162

The actual installation to the end of 1929 in water wheels and turbines, as shown in column 4, amounted to 5,727,162 horse power, representing slightly more than 13 per cent of the recorded potential resources

The progressive development which has taken place since the beginning of the present century is best illustrated by a diagram, and the curve shown in Fig 1 is remarkable not only for its continuous

upward trend but also for the increasing degree of steepness which characterises its progress It is

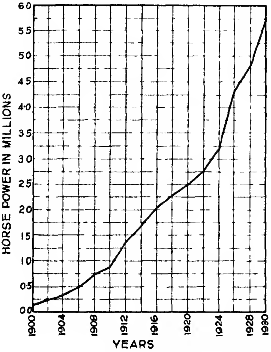

FIG 1 — Growth of water power development in Canada 1900–30

surprising to realise that thirty years ago hydro electric installations in the Dominion did not amount to one quarter of a million horse power

Obviously it is impossible in the space at disposal to allude in any detail to the various installations which have materialised during the past year A few observations on one or two stations of outstanding importance is all that may justifiably be attempted in this brief review of the general situation

The province of Quebec led the way with an addition of more than 208,000 horse power brought into operation, including chiefly the new plant (72,000 horse power) of the Montreal Island Power Company on Des Prairies River, near Montreal, and additional units to the existing stations of the Gatineau Power Company and the Shawinigan Water and Power Company The Gatineau Power Company added fourth units of 24,000 h p and 34,000 h p respectively to the stations at Farmers Rapids and Chelsea Dam, illustrated in NATURE of July 27, 1929 A third station on the same river at Paugan Falls, a view of which is shown in Fig 2, has a present equipment of 204,000 horse power which is shortly to be increased to 272,000 horse power The same Company also completed the construction of a storage dam at Cabonga Lake, an important upper tributary of the Gatineau River, providing a reservoir with a capacity of 45 thousand million cub ft This reservoir is the property of, and is now being operated by, the Quebec Streams Commission in conjunction with the Baskatong reservoir above the Mercier dam, with a capacity of 100 thousand million cub ft, located lower down the river The Shawinigan Water and Power Company added a 43,000 horse power unit (eighth in succession) to No 2 Shawinigan Falls Station (vide NATURE, Sept 3, 1927)

Important projects are in hand at Chute a Caron on the Saguenay River, where four units of 65 000 h p each are about to be installed and at Beauharnois, on the St Lawrence, immediately above Montreal, where an initial installation of 200,000 or possibly 350,000 h p is projected before the end of 1932 This latter outstanding undertaking includes a diversion canal for power and navigation, approximately 15 miles in length The inauguration of constructional operations by the Governor General of Canada was referred to in NATURE of Dec 14, 1929, p 930, in which some particulars of the project were given

FIG 2 — Gatineau Power Company's development at Paugan Falls on the Gatineau River Quebec Present installation, 204 000 h p ultimate 272 000 h p By courtesy of the Dominion Water Power and Reclamation Service Ottawa Canada

The province of Ontario includes the renowned Niagara Falls, or, at any rate, a portion of them During 1929, work was advanced on the installation of a tenth unit of 58,000 horse power at the Queenston Station, it is expected to be completed this year Another important development was the completion of the 28,200 horse power installation of the International Nickel Company of Canada at the Big Eddy Dam on the Spanish River

Table No 2 enables an idea to be formed of the distribution of the developed power among the leading industries in the various provinces Supplies to central electric stations constitute by far the major portion of the consumption and there is every indication that the proportion used for this purpose will continue to increase From a percentage of 33½ at the beginning of the century it has grown to more than 84 per cent A number of factors contribute to this increasing use, notably the extensive economic radius of modern electrical transmission, combined with the fortunate location of water power sites in relation to centres of population and industry without adequate local fuel supplies The provinces of Ontario and Quebec, as is well known, are entirely destitute of geological deposits of coal The special adaptation of hydraulic power to central electrical station operations is emphasised by the fact that the last completed central station census, namely, that for the year 1927, shows that more than 95 per cent of the total main plant equipment is in hydraulic generating stations and that this equipment produced almost 99 per cent of the total electrical output[1]

It is noteworthy that at the present time there are in Canada a total of 312 hydro electric central stations, possessing an aggregate of 4,817,486 horse power, distributing supplies for purposes of all kinds, including traction, lighting, heating, and motive power generally Municipalities and public organisations control 97 of these stations, containing 237 turbines aggregating 1,297,398 horse power The remaining 215 stations, with an installation of 581 turbines and a combined capacity of 3,520,088 h p are owned by various commercial organisations

The next most important source of consumption for hydro electric power in Canada is the pulp and paper industry—the chief manufacturing activity of the Dominion One of the most conspicuous features of industrial progress in Canada has been the growth of this industry, arising out of the occurrence of enormous supplies of growing pulp wood in close proximity to readily developable water power of a magnitude adequate to provide the large supplies of power essential to the conversion of the raw material into the finished product The value of this fortunate conjunction and the importance of ample supplies of economically produced power may be gauged from the fact that practically 100 horse power is required per ton of daily output of newsprint

Column 4 of Table 2 shows the amount of electro hydraulic power absorbed in miscellaneous industries, including mining, to which it is an invaluable adjunct in consequence of the prohibitive cost of fuel power Columns 6 and 7 are of interest in instituting a comparison of power development per head of population The figure for the whole of Canada, 584 per thousand, compares extremely favourably with that of other countries, being considerably in excess of most and rarely exceeded, or indeed even approached

TABLE 2—DEVELOPED WATER POWER IN CANADA, JAN 1, 1930

DISTRIBUTION BY INDUSTRIES AND PER 1000 POPULATION

Province	Turbine Installation in h p				Population June 1, 1929	Total Installation per 1000 Population (h p)
	In Central Electric Stations	In Pulp and Paper Mills	In other Industries	Total		
British Columbia	417 960	81 000	60,832	559,792	591,000	947
Alberta	70,320	—	212	70,532	846 000	83
Saskatchewan	—		35	35	886,700	0 04
Manitoba	311,925	—		311,925	663,200	470
Ontario	1 616,773	240,880	94,402	1 952,055	3,271,300	597
Quebec	2,238 525	221,160	135,745	2,595,430	2,690,400	964
New Brunswick	83,910	19 778	8 943	112,631	419,300	269
Nova Scotia	77,697	16 008	15,419	109 124	550,400	198
Prince Edward Island	376	—	2 063	2,439	86,100	28
Yukon and North West Terr	—	—	13,199	13 199	12 400	1063
Canada	4,817,486	578,826	330 850	5,727,162	10,016,800	572

Col 2 includes only hydro electric stations which develop power for sale
Col 3 includes only water power *actually developed* by pulp and paper companies In addition to this total pulp and paper companies purchase from the hydro power central electric stations totalled in Col 2 electric energy for power purposes estimated at about 860,000 h p, making a total of about 1 438 826 h p actually used for power purposes in the manufacture of pulp and paper A considerable amount of off peak and surplus power is also purchased for use in electric steam boilers
Col 4 includes only water power *actually developed* in connection with industries other than the central electric station and pulp and paper industries These industries also purchase power from the central electric stations totalled in Column 2
Col 5 totals all turbines and water wheels installed in Canada
Col 6 shows the population at June 1 1929 as estimated by the Dominion Bureau of Statistics
Col 7 averages the developed water power per 1000 population

Obituary

DR H J B FRY

DR H J B FRY died on May 5 at the early age of forty four years, from an acute infection acquired at a post mortem examination in the course of his work at the Cancer Hospital London, where he had held the post of pathologist since 1922 In the investigation of cancer and especially in the organisation of this work by the British Empire Cancer Campaign, he had found a field for which he was, both by nature and experience, peculiarly well fitted He was educated at Charterhouse, Magdalen College, Oxford, and St Thomas's Hospital His earlier investigations, both before and during the War, dealt with a wide range of biological and clinical subjects he published papers on the coagulation of the blood in fishes and tunicates, the nervous control of the cephalopod heart the histology of the pituitary gland in diabetes and the use of immunised blood donors in the treatment of pyogenic infections He was thus well acquainted with the complexities and pitfalls of research both in the laboratory and in the wards, and he had exactly that combination of enthusiasm experience, and caution which is most needed in cancer research Moreover, at his home in Welwyn Garden City he was a magistrate and a councillor, and in these positions, and in the difficult work of a committee for placing convicted persons on probation he had gained a good knowledge of the conduct of business

As secretary of the Investigation Committee of the British Empire Cancer Campaign, it fell to Dr Fry's lot to receive those abundant suggestions, of all possible degrees of rationality, which are offered to the Campaign for the investigation and treatment of cancer He served the *Cancer Review*, which is published by the Campaign and abstracts the literature relating to cancer, from its beginning as sectional editor, and later as chairman of the editorial committee, and the volumes of this journal, of which the fifth is now being issued, contain a mass of good work by him He took endless trouble over his abstracts, and they are models of thoroughness

In his own investigations Dr Fry had attacked two of the most difficult problems, namely, the search for immune reactions which might possibly serve as some basis for the diagnosis, and for the treatment, of cancer The time given to him was too short to allow of much progress in these immense tasks, and his published writings show a beginning only His flocculation method for the diagnosis of cancer gave useful results within certain limits, and he was constantly testing possible improvements in the technique Throughout this research he worked with material from human sources, under clinical conditions, and his work could be under no reproach that it applied only to the artificial conditions of the laboratory

In his recreations Dr Fry was a fine athlete, a cricketer, tennis-player, and rider, and a lover of literature with an especial devotion to Hardy's "Dynasts" and Gilbert Murray's translations of Greek drama He was not a man who spoke of his ambitions, but anyone who knew him well will have no doubt that these lay in the direction of manifold and increasing service to human welfare

DR GUSTAF EKMAN

WE regret to record the death at the age of seventy seven years of Dr Fredrik Gustaf Ekman From the *Göteborgs Morgenpost* of Feb 27, we learn the following details of his life Ekman was born at Stockholm in 1852, and when he was nine years old, his family moved to Goteborg, where his father and brother obtained posts in the Carnegie sugar refinery As a student at the technical high school of Goteborg and Chalmers technical institute, and afterwards at Wiesbaden and Uppsala, Gustaf Ekman specialised in scientific technology with the view of acquiring full knowledge of the technique and the chemico scientific basis of sugar refining On his return to Goteborg in 1880 he obtained the post of technical director in Carnegie's refinery, and for twenty years as technical director and then as one of its managing directors Ekman rendered considerable service to the development of the Swedish sugar manufacture

In his student days in Uppsala Ekman showed leanings towards natural science and marine research in particular appealed to him Some preliminary marine investigations were begun in 1876 in collaboration with Prof A W Cronander, professor of chemistry, and in the following year the State fitted out and financed a Baltic expedition in which Ekman participated Next year he received from the local authority in Bohuslan a request to investigate the sea off the coast of Bohuslan from the point of view of the herring fishery, and his pioneer discoveries awakened widespread interest in marine biological and fisheries research Indeed, his name will always be associated with that of his friend Prof Otto Pettersson in the annals of Swedish hydrographic work Since 1904 he was associated first as expert and later as delegate with the International Council for the Exploration of the Sea

WE regret to announce the following deaths

Dr Joseph L Markley, professor emeritus of mathematics at the University of Michigan, known for work on Bessel functions and the theory of functions, on April 20, aged seventy years

Dr William H Nichols, past president of the American Chemical Society, known for his work on the metallurgy of copper and in industrial chemistry, on Feb 1, aged seventy eight years

Prof Katsusaburo Yamagiwa, emeritus professor of pathology and pathological anatomy at the Tokyo Imperial University, member of the Japanese Imperial Academy, who carried out important investigations on cancer, showing in 1915 that it could be produced by prolonged application of coal tar to the skin, on Mar 2, aged sixty six years

News and Views

THE presidents of seven American universities have furnished the Scientific Research Committee of the American Association for the Advancement of Science with statements of the salaries paid to executive officers, professors, associate professors, and assistants in 1900 and 1925 The Universities are Yale, Harvard, Ohio State, Michigan, Illinois, Wisconsin, and California The figures, with other statistical material, provide Prof W A Noyes, of the University of Illinois, with the basis for an interesting argument published in *Science* for April 18 Dr Noyes says that professors in American colleges and universities are not receiving their fair share of the returns from the rapidly increasing prosperity of the country In the twenty five year period, nominal wages in America increased by 200 per cent, corresponding to a real wage advance of 50 57 per cent Since the nominal salary increase among professors was only 87 122 per cent, their purchasing power in 1925 was actually below the 1900 level To be equitable, a salary of 2000 dollars in 1900 should have been 6000 dollars in 1925 Dr Noyes also compares academic with scientific industrial salaries earned by his own students of the 1918–1928 class The average salary of those who had taught for four to ten years was 3472 dollars, and the average for industrial workers for the same time 5619 dollars The highest initial academic salary was 3500 dollars paid to a woman in a women's college, and the highest three initial salaries for industrial work were 4800, 4000, and 3840 dollars respectively "It seems evident", he says, "that unless these conditions can be remedied our universities must be content to fill their teaching positions with mediocre men" He puts an 'attractive' salary for a professor in present day America at 20,000 dollars (say £4000) a year

So much for the 'academic' point of view That an American business man, Mr Edward A Filene, president of a Boston commercial organisation, should discuss the salary problem from a more detached point of view seems to be an adroit move His address to the Committee does not show him to be better informed or more enlightened than some of our best men of affairs and industrialists The emphasis falls differently It is impossible to do more here than outline the salient points of an address interwoven with historical and economic allusions His points were (1) That it is idle to accuse the scholar of impracticality because he does not descend to the market place to earn a living by 'useful work' by so doing he would become useless as a scholar, and to refuse to do so is sound practicality (2) That whether the taxpayers should or should not control education need not be discussed, they cannot Prohibition of education is only theoretically possible Science has made it practically impossible (3) American business has discovered that it cannot be run on opinion, however traditionally correct and authoritative, but only by actual scientific research, which is specialists' work What is happening is not the commercialisation of scholarship, but a new revolution of economic life by science The power that comes from science cannot in modern conditions be used selfishly it will receive many times its present reward Mr Filene appears to believe that those educational ideals that really matter will be more secure in the new economic order than they are now because they are essential to the life of science and the aims of human effort Another business man, a newspaper magnate, told the Committee that he regarded scientific workers who willingly and unnecessarily laboured on a miserable stipend as "economic imbeciles" It would be unlike the Americans to leave the matter there

THURSDAY last May 29, was the three hundredth anniversary of the birth of King Charles II, an event which should be, for diverse reasons, of interest to men of science Proclaimed king on May 8, 1660, in Westminster Hall, Charles arrived at Dover, from the Hague, on May 29, his thirtieth birthday Portraits in national and private collections familiarise the King's lineaments in manhood A faithful representation of him (its particular source is not known) is seen in the finely executed pen and ink drawing in the second charter (1663) of the Royal Society As to personality, Evelyn enters him as "débonnaire, easy of access, naturally kind hearted, and of an excellent temper" In his sketch of the rise of scientific study in Scotland (1909) the late Sir William Turner goes further, remarking "Charles II lives in the recollection of most people as a lover of pleasure, untrustworthy, indifferent to the welfare of his people and ready to sacrifice the interests of his country to gratify his taste for luxury and ease" In early life Charles received tuition in mathematical studies from Hobbes, he had mechanical skill and he possessed a turn of mind which led him to discuss the philosophical topics of the period Pepys, however, noted that the King "mightily laughed at Gresham College for spending time only in weighing of ayre and doing nothing else since they sat" What justly, and in charitable construction, can we say of this monarch, then, from a point of view less relating to conduct and more to corporate effort ?

IN brief retrospect we may recall certain national institutions actually attributable to Charles II, through Royal edict, passing over special formative influences (1) The Royal Society of London took shape amongst a group of men The King might have adopted and maintained a negative attitude on the contrary, he was friendly throughout To his signature in their charter book he appended the word Founder (2) The Royal Observatory at Greenwich was built in 1675 Flamsteed records the facts concerning its establishment, and the immediate interest shown by Charles II in its foundation (3) The Royal Mathematical School of Christ's Hospital centred in a plan of education for service in the navy or in merchant craft A Royal charter, granted in 1673 by Charles II, affirmed there might be forty boys "there taught and instructed in the Art of Navigation and the whole Science of Arith-

matique untill their age and competent proficiency in those parts of the Mathematiques shall have fitted and qualified them in the judgment of the Master of the Trinity House." It is true that little was done, however, by the King towards the after maintenance of his foundation. (4) On St. Andrew's Day 1681, Charles II. granted a patent which incorporating the physicians, founded the Royal College of Physicians of Edinburgh, a recognition of the claims of the northern city which has redounded to the honour of medicine and learning. Charles II. died in 1685, and was buried in Henry VII.'s Chapel in Westminster Abbey.

IN his Friday evening discourse at the Royal Institution on May 23, on some scientific instrument makers of the eighteenth century, Mr. R. S. Whipple stated that there is little evidence to show that scientific instrument making, as a craft, had obtained a position of any importance in Great Britain before the sixteenth century. The demand for instruments to assist navigation became more insistent as new lands were discovered and the length of the voyages increased. The discovery of the telescope in 1608 and the development of the microscope, largely due to Hooke and Leeuwenhoek in the middle of the seventeenth century, gave a great impetus to the manufacture of scientific instruments. John Marshall, by his skill in developing a method for grinding lenses and by the improved designs of his instruments became the foremost instrument maker of the latter part of the seventeenth and of the early part of the eighteenth century. Benjamin Martin (1704–1782) who began life as a ploughboy, later became well known as an author of popular scientific books and as an instrument maker. He developed many improvements in the microscope and other instruments. One of his contemporaries, George Adams, became, perhaps, the best known instrument maker of the eighteenth century. He specialised in the manufacture of globes and surveying instruments, and also in microscopes. He also made a large number of instruments for George III., which are preserved in the Science Museum at South Kensington. They are outstanding examples of finished workmanship. Dolland, Ramsden, and Herschel were other outstanding instrument makers of the eighteenth century.

IN the early days of long distance telephone communication, many thought that it would be a boon if the speaker and listener could see one another during the conversation. The difficulties at first sight seem insuperable, yet apparently they have, with the important exception of cost, been satisfactorily overcome. At a Press view on April 9 in New York, the feasibility of two way television was demonstrated. An 'ikonophone' booth was erected in one building and a similar booth was erected in another building some distance away by the Bell Telephone Co. The speaker enters one booth and a 'scanning' beam of mild blue light rapidly and continuously passes over his face. As in ordinary television, this enables the listener to see the speaker. A similar beam traverses the face of the listener, thus making him visible to the speaker. The television booths themselves are lighted with a dim orange light to which the photoelectric cells are insensitive. An ordinary telephone mouthpiece cannot be used, as this would hide part of the speaker's face. The telephone transmitters, therefore, are concealed in the sides of the booth. The received image is formed eighteen times a second and is of the familiar black and pink type seen with neon reception. The increased sensitivity of modern cells and the use of the faint blue scanning beam have reduced the dazzle and glare so much that the conditions are now quite tolerable. Dr. Jewett states, however, that the terminal apparatus is at present very complicated and expensive. A description of the apparatus is given in the *Wireless World* for May 14.

IN the *Times* for May 23 an account is given of a television performance of a play which was seen by an audience of 300 people in a theatre in New York although the actors were more than a mile away in the General Electric Laboratory. The screen was six feet square and it is stated that the actors were clearly visible; also by means of loud speakers their voices were audible in every part of the building. To give variety to the entertainment one member of the vaudeville company came to the theatre after the first part of the act had been shown and the act proceeded with him playing his part on the stage while his partner was seen by television. The performance was slightly marred by the tendency of the picture to sway slightly, due probably to the synchronisation not being quite perfect. The pictures are said to have been very much superior both in definition and freedom from flickering to cinema pictures when they first began to be shown. Like everything new it is attracting audiences and the success of the demonstration has led the management of the theatre to retain television as a regular feature of their programme.

AN account has been received from Mr. A. S. E. Ackermann of the occurrence of three successive waterspouts within half an hour, at a point off the Italian coast four miles west of Portofino Vetta in the forenoon of April 20. The first was the largest, and lasted about ten minutes, while those that followed when the first had drifted away to the west each lasted about four minutes. The description of the actual spout does not suggest anything abnormal—in each case a column of spray first rose from the water, and afterwards the characteristic column of cloud descended to meet the spray, the latter rising at the same time. The cloud column would therefore appear to have developed when the parent atmospheric whirl increased in intensity. The remarkable feature of the phenomenon is the apparent repeated formation at a particular point on the sea at a time when a definite general drift of wind was evidently present, for the atmospheric conditions responsible for a spout might be expected to drift with the wind, and any reappearance of the phenomenon would naturally

be farther to leeward—unless of course there should be a nearly stationary patch of water warmer than the rest of the sea in the neighbourhood, capable of a trigger-like action upon atmospheric conditions already verging upon instability

PROF A C LANE, writing from the Library of Congress, Washington, in connexion with the discussion on geological climates at the Royal Society on Mar 27 (NATURE, April 5, p 546), raises two interesting points First, he suggests that there may have been during geological ages a slow variation in the density of the atmosphere, which would have a definite climatic effect On this it may be remarked that the great flying reptiles of the Mesozoic probably could not have lived in an atmosphere much rarer than the present, they have in fact been adduced as an argument for greater density In the absence of any real evidence, however, it is idle to speculate on the possible climatic effects of such changes The second point is of greater interest Suppose a black smoke deposit could be laid over the surface of the Greenland ice sheet, what would be the effect? The experiment would no doubt add something to the earth's heat, for part of the radiation now reflected back to space would be absorbed, and if the blackening could be maintained, there would presumably be a local amelioration of climate, perhaps comparable with that which occurred about the tenth century A D But immediately the ameliorating influence in the tenth century, whatever its nature, was withdrawn, the Greenland ice sheet increased again in extent, and one fears that any artificial attempt in the same direction would be equally transient There is room for speculation whether the existing meteorological system would remain stable under great changes of solar or geographical conditions, but there is little doubt that it is stable under small disturbances, and tends to restore existing conditions as soon as the disturbing factor is withdrawn

IT is stated in the daily Press that a conference of representatives from all over New Zealand, convened by the Government, met on May 7 in Christchurch to consider the problem of the increase of deer So greatly have the herds developed in recent years that they have spread into new areas and are becoming a menace to farm and forest lands Red deer and fallow deer were introduced into New Zealand in the sixties and seventies of last century, and since that time various other species, such as the Indian sambar, the American wapiti and moose and Virginian deer, have been set free and become firmly established The naturalisation of these handsome animals was hailed with satisfaction by sportsmen and by naturalists, who regarded their presence as an asset to a noble environment Their dispersal from the limited areas in which they were originally set free to new valleys and districts was recorded with admiration, and their safety was ensured by protection, for the deer belonged either to private acclimatisation societies or to the State, which also took a part in the introductions Twenty years ago deer were still being introduced

Now comes the announcement that the deer have become a pest, and the Minister of Internal Affairs, who presided at the conference referred to, declared that he himself favoured the removal of all protection from deer and chamois From the short cabled message it would appear that the body of the conference deemed the menace too serious to be met even by such a measure, a unanimous decision was reached that extermination was a matter of urgency, and the Government was asked to supervise the destruction of the animals Without evidence, we have no means of judging whether this was a reasonable decision on the part of the conference—there are always people who, when their interests are threatened, are ready to call for the extermination of the aggressor But even if the case against the deer is exaggerated, the venture which began in blessings and after half a century of commendation is ending in cursings, is one of the most emphatic warnings of recent years against the setting free of foreign animals in a new land

AMONG the recent acquisitions of the British Museum (Natural History) are the following The Department of Zoology has received the skin and skull of the rare East African bongo (*Boocercus eurycerus isaaci*) from the Aberdare Mountains, Kenya Colony, and also an unusually interesting collection of corals comprising about 300 specimens with full field notes, presented by Dr Cyril Crossland, by whom they were collected in the course of his investigations on the coral reefs of Tahiti Through the kindness of Mrs V D Hughes of Winchester, the Department of Entomology has received a selection of Lepidoptera from the collection of the donor's father, the late Andrew Swanzy The series includes practically all the type specimens in the Swanzy collection described by the late Dr A G Butler and figured by him in one of his earliest works ("Lepidoptera Exotica", 1869–74) Under the will of the late Prof F V Theobald, who died on Feb 11 last, his collection of Aphididæ, consisting of 9258 microscope slides carrying preparations of specimens, among which are 402 types, 19 co types, and 311 paratypes, goes to the Museum The collection includes the material upon which its late owner based his monograph "The Plant Lice or Aphididæ of Great Britain" (3 vols 1926–29), and also his reports on African and Indian Aphididæ This bequest makes the British Museum collection of this family the finest in the world The most important addition to the Geological Collections is a set of four specimens of an extinct aquatic reptile, *Mixosaurus*, from the Alpine Trias of the Lake Lugano district of Italy This genus is a somewhat aberrant form of Ichthyosaur in which the characters of several bones are reminiscent rather of land than of water animals It was about three feet long and in shape rather like a porpoise, and had paddles for swimming and an elongated tail fin The specimens purchased include a fine skull and lower jaw, the sclerotic ring of one of the rather large eyes, and a good portion of the vertebral column Paymaster Commander T M Salter, R N, has presented to the Department of Botany a collection of

1400 prepared and named South African flowering plants

RESEARCH work in Germany from 1920 to 1927 is outlined in "Deutsche Forschung", a brochure issued as an extract from the fifth Report of the Notgemeinschaft der Deutschen Wissenschaft. Its 116 pages give some idea of the immense range of activities encouraged by thousands of grants in aid during years of impoverishment. All academic studies have benefited from theology, philosophy, and philology to biology, agriculture, and medicine. Assistance has taken such forms as subventions for printing expenses of periodicals, grants to research scholars and explorers, publication of works almost completed before the War, provision of expensive physical apparatus and foreign literature. In every department it has been necessary to consider which magazines to support, and in restricting quantity to improve quality; hence two are supported for international law, three for psychology, ten for geology. The most striking venture has been the exploration of the South Atlantic by the research ship *Meteor*. Some two years were spent on about a dozen roughly parallel routes between Africa and South America. Sea and air, winds and currents, plankton and ocean floor were examined by specialists. Other leading lines have been vitamins, ultra-violet and penetrating radiations, cathode rays, vacuum tubes, and spectroscopy. Preparations have been made for total eclipse expeditions and for observations of the opposition of Eros. As a guide to recent research in Germany the book should be valuable to the historians of science and to publishers, editors, and librarians.

WE have received a copy of the Year book 1928–30 of the Sixth Achema or Great International Exhibition of Chemical Apparatus, which is to be held at Frankfurt on the Main on June 10–22. The book contains much useful information about the development of all kinds of machinery and apparatus which is designed for use in chemical technology. These descriptive sections have been compiled by well-known experts. Dr Kirschbaum of Karlsruhe gives an interesting account of the method pursued in the technical high schools of adapting the curricula to the needs of the young engineering chemist. It is recognised that the experience gained from a close and intensive study of the main processes in common use in chemical factories is much more valuable than a superficial but more comprehensive course of theoretical studies. Provision is also made for the students to complete their training by carrying out research, the experience thereby gained being of immense ultimate value to industry. Herr Jentgen of Berlin describes some of the mechanical problems encountered in the rayon industry, and other articles deal with the standardisation of plant and apparatus, both large and small. In the industrial section the characteristic properties of special rustless steels, aluminium and its alloys, and bakelite are described. There is also a section upon scientific apparatus, such as Sartorius' balances, electric high temperature ovens and apparatus for electrometric titrations. This is followed by a chapter upon various types of chemical plant and machinery. An interesting feature of the book is the inclusion of more than fifty portraits of leading German authorities in chemical technology. Copies may be obtained on sending two international postage coupons to Dr Max Buchner, Hannover.

THE May issue of the *Empire Review* contains an article on vocational psychology by Mr Eric Farmer. He points out that the subject suffered in its initial stages from too great publicity, so that uncritical people tended to believe that it was a simple matter to devise tests calculated to select those people likely to do well at any given occupation. Research, however, has revealed that vocational psychology is far more complicated than was at first supposed. The term 'vocational fitness' can no longer be limited to the narrower economic factors involved in ability actually to do a certain type of work, or produce during a test period a large output; it must also include relative freedom from accidents and sickness and satisfaction to the worker from his work. Mr Farmer discusses the principles involved in the problems both those belonging to the individual and those to the work. He criticises some of the more usual methods of devising selection tests and shows that in some cases false assumptions are made. He does not, however, imply that vocational guidance and selection are impossible, but points out that the early over-enthusiastic stage is over and that the whole subject has now entered upon a more scientific experimental period. The article is a very valuable critical survey and of importance to all engaged in this very difficult aspect of psychology.

THE Faraday Society will hold a general discussion on "Colloid Science Applied to Biology" at Cambridge on Sept 29–Oct 1. A number of workers have been invited to prepare reports on the physico-chemical problems which are encountered in biological work and especially in the study of living matter. These reports will be circulated as far in advance of the meeting as possible so that they may be fully considered by workers in the fields of physical chemistry and biology, and so that considered contributions may be made to the discussion in due course. Sir William Hardy will preside over the first part of the meeting, devoted to "Equilibrium in Protein Systems" and will give an introductory address. Those invited to present reports are Prof A V Hill, Dr R A Gortner (Minnesota), Prof E J Bigwood (Brussels) and Prof W Pauli (Vienna). Sir Gowland Hopkins will preside over a discussion on "The Structure of Living Matter" and will give an introductory address. The following have been invited to give reports: Dr Wilmer (Cambridge), Prof W H Lewis (Baltimore), Prof R A Peters (Oxford), Prof Fremiet, Prof Hans Pfeiffer (Bremen), and Dr J H Quastel (Cambridge). The discussion should prove of considerable interest, and the following prominent overseas workers, more particularly in the field of physico-chemistry, have already accepted invitations to take part: Prof E F Burton (Toronto), Prof J Duclaux (Paris), Prof H

Euler (Stockholm), Prof H Freundlich (Berlin Dahlem), Prof H R Kruyt (Utrecht), Prof Wo Ostwald (Leipzig), Prof Wo Pauli (Vienna), Prof S P L Sørensen (Copenhagen), and Prof T Svedberg (Uppsala)

The Burmese earthquake of May 5 (Nature, May 17 p 752) was followed on the next day by an equally destructive shock in north western Persia The epicentre was in the Azerbaijan district and not far from Salmas a town which lies about 80 miles west of Tabriz and 400 miles north west of Teheran The early reports estimate the loss of life as about 2000 The immediate neighbourhood of Salmas has been comparatively free for many years from destructive earthquakes though near Tabriz there is a centre that has been the source of several great earthquakes during the last century and especially in 1879 and 1883 As is stated in the *Daily Science News Bulletin* (for May 10) issued by Science Service Washington D C, there has been lately a period of seismic tranquillity unequalled in the recent annals of seismology From Dec 17 1929 to May 5, 1930 only one rather strong shock (near Borneo on Mar 26) has been recorded

Many friends of Dr G Claridge Druce assembled at the Great Central Hotel, London, on May 23, to offer him congratulations on the attainment of his eightieth birthday Sir Maurice Abbot Anderson, president of Flora's League, occupied the chair, and Viscount Grey of Fallodon gave an address on some aspects of outdoor natural history, the pursuit of which always brings delight and often leads to knowledge of significant scientific value On behalf of the Botanical Exchange Club, Lord Grey presented Dr Druce with a cheque which, it is understood, will be used by him to purchase a plot of land where a particular wild plant is found, and afterwards to hand over the land to the Society for the Preservation of Nature Reserves so that this rare plant may be preserved in England

At a preliminary meeting held at the Technical College, Cardiff, on May 21 it was decided to form a Microscopical Society of Wales, for the acquisition and diffusion of knowledge gained by microscopical research The original suggestion was for a local body, but the preliminary inquiries brought so much support that a body on a wider basis was considered feasible The committee appointed at the preliminary meeting met on May 23 and it was decided to hold an exhibition on June 2 and an inaugural meeting on June 4 The exhibition will illustrate the importance of the microscope in the sciences and will be open to the public Meetings so far have been held at the Technical College, the authorities of which have put the biological laboratory of the College at the Society's disposal on one evening weekly throughout the year Mr A F Harris, 44 Partridge Road, Cardiff, has been appointed secretary and will organise the exhibition

Sir Edward Sharpey Schafer will open the new buildings of the Department of Research in Animal Genetics of the University of Edinburgh at the King's Buildings, West Mains Road, on Monday, June 30, at noon

Mr H T Tizard, Rector of the Imperial College of Science and Technology, is to succeed Sir J J Thomson as president of the Association of Special Libraries and Information Bureaux, at the annual conference of the Association to be held at New College, Oxford, in September

The forty first annual Conference of the Museums Association will be held at Cardiff on June 23–27 under the presidency of Sir Henry Miers The provisional programme includes an address by Dr Cyril Fox on the National Museum of Wales, and another by Dr O Lehmann director of the museum at Altona Prussia papers are to be read on the opportunities and difficulties of the parent museum in connexion with museum affiliation (Dr Cyril Fox), rural services (Mr W C Sprunt and Dr F W Woodhead) geology and botany in relation to the small museum (Dr F J North and Mr H Augustus Hyde respectively) Throughout the meeting there will be an exhibition of museum cases, fittings and appliances, etc in the Engineers' Institute Park Place Cardiff The local honorary secretary for the meeting is Mr A H Lee, National Museum of Wales Cardiff

Applications are invited for the following appointments, on or before the dates mentioned —A radiologist at the Crumpsall Hospital, Crumpsall, Manchester—The Town Clerk, Town Hall, Manchester (June 2) A lecturer in electrical engineering at the Dudley Technical College—The Director of Education, Education Offices, Dudley (June 4) A part time demonstrator in chemistry at King's College of Household and Social Science—The Secretary, King's College of Household and Social Science, Campden Hill Road, W 8 (June 7) An instructor in the electrical engineering and physics department of the School of Engineering and Navigation, Poplar—The Education Officer (T 1), County Hall, S E 1 (June 7) A lecturer in mathematics at the Portsmouth Municipal College—The Secretary, Offices for Higher Education Municipal College, Portsmouth (June 7) An assistant marketing officer under the Department of Agriculture for Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (June 7) A graduate assistant in electrical engineering at the Wolverhampton and Staffordshire Technical College—The Clerk to the Governors, Education Office, North Street, Wolverhampton (June 9) A junior lecturer in the Department of Civil Engineering of the University of Liverpool—The Registrar, The University, Liverpool (June 10) A resident lecturer in hygiene at the Bangor Normal College—The Principal, Normal College, Bangor, North Wales (June 10) A head of the Department of Navigation at the Sir John Cass Technical Institute and Nautical School—The Principal, Sir John Cass Technical Institute, Jewry Street, E C 3 (June 10) Two veterinary surgeons under the South West Africa Administration—The

Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C 2 (June 11) A lecturer in charge of the Clowne Mining Institute and a lecturer in electrical engineering at two mining schools—The Director of Education, County Education Office, Derby (June 11) A lecturer in electrical engineering mainly at the Heanor Mining and Technical School—The Director of Education, County Education Office, Derby (June 11) A lecturer in science at the Ebbw Vale Mining and Technical Institute—The Director of Mining Education, County Hall, Newport, Mon (June 12) A lecturer in geography at Birkbeck College—The Secretary, Birkbeck College, Breams Buildings, Fetter Lane, E C 4 (June 13) A Paterson Research scholar in the Cardiographic Department of London Hospital—The House Governor, London Hospital, E 1 (June 14) A junior lecturer in geography in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C 2 (June 14) A warden of the County Farm Institute, Moulton, and assistant county agricultural organiser, also a junior agricultural assistant, each under the Northamptonshire County Council—The Secretary for Education, County Education Offices, Northampton (June 14) A glass blower in the National Research Laboratories of Canada—The Secretary-Treasurer, National Research Council, Ottawa, Canada A Head of the Building Trades Department of the Bury Municipal Technical College, and a teacher of handicraft (woodwork and metal work) in the Bury Municipal Secondary School and Junior Technical School (jointly)—The Director of Education, Education Offices Moss Lane, Bury A teacher of electrical engineering at the Watford Technical School—The Principal, Technical School, Watford A research assistant at the Liverpool School of Tropical Medicine—The Hon Dean, School of Tropical Medicine, Pembroke Place, Liverpool An assistant to the adviser in economics at the Harper Adams Agricultural College—The Principal, Harper Adams Agricultural College, Newport, Salop Two assistant entomologists under the Division of Economic Entomology of the Commonwealth of Australia Council for Scientific and Industrial Research—F L McDougall, Australia House, Strand, W C 2

ERRATUM—The name of the author of the paper on "The Bavenda" delivered at the Royal Anthropological Institute on May 13, to which reference is made in NATURE of May 24, p 789, is H A Stayt, and not H A Stuyt, as printed

Our Astronomical Column

The Lowell Planet—It is announced from the Lowell Observatory that the name Pluto has been adopted for this planet

The assumption that the image found on a plate taken at Uccle Observatory, Belgium, on Jan 27, 1927, belongs to the planet enables fairly trustworthy elements to be deduced The first of the following orbits is by Prof Banachiewicz (*U A I Circ* 282), the second by Dr A C D Crommelin (*B A A Circ* 93) both are for the equinox of 1930 0

T	1984 Oct	1984 Dec 5 4 U T
ω	108° 56′	106° 45′ 40 0″
Ω	109 22	109 21 23 6
i	17 12	17 5 34 5
ϕ	17 19	16 41 49 7
log a	1 6110	1 6158060
log q	1 4576	1 4687050
Period	260 9 y	265 2828 y

Both orbits place the perihelion point slightly inside Neptune's orbit This is the first known instance (apart from the minor planets) of the orbits of two planets overlapping, the two orbits are separated by about 4 units, owing to the high mutual inclinations It will be seen that according to these orbits the planet will be steadily growing brighter for the next 54 years, and will be brighter than at present for 108 years

It is of interest to give for comparison the orbit predicted by Prof P Lowell in his memoir published in 1915, p 105, and reduced here to the equinox of 1930 longitude of perihelion (that is $\omega + \Omega$), 205°, i, 10° (estimated), ϕ, 11° 39′; log a, 1 6335; log q, 1 5355, Period, 282 years, T, 1991 March It will be seen that there is good accord both in the shape and position of the orbit and in the planet's place in it

Lowell did not give a prediction of Ω, but Prof W. H. Pickering in 1919 predicted Ω as 100°, i as 15°, both quite good approximations.

Large Fireball—A large fireball was observed on May 16 at 9 h 14 m P M by Mr R Skelton from Washington Station, Workington It appeared to be as bright as the full moon and it exhibited an orange colour It was first seen in the south south west, travelling to west south west at altitudes from about 23° to 13° The commencement of the flight was not witnessed, but the visible portion occupied about four seconds When it came into view it showed a pear shaped head which left a trail of bright sparks, no sound was heard and there were no stars visible to help in locating the path accurately The brilliant object was also noticed by a boy at Seaton From this place it was first seen in the south at about 25° altitude, and it passed across a window in its journey to south west, where it glided behind trees, the tops of which are about 20° high It was described as emitting a white light and shedding bright fragments as it traversed its course

Tercentenary of Kepler's Death—The tercentenary occurs this year of the death of Johann Kepler, and the May number of the *Scientific Monthly* contains an interesting review of Kepler's work by Prof Florian Cajori of the University of California Many of Kepler's original diagrams are reproduced, and we are reminded how unwearying was his search for harmonies connecting the planetary distances and periods His success in deducing the three famous laws is well known, but there were very many other researches, notably the attempt to connect the spheres described on the planetary orbits with the five regular solids The diagram in which the elliptical orbit of Mars was drawn for the first time is reproduced from "Astronomia Nova" The orbit is surmounted by a symbolical figure of Victory in a chariot

We see how study of Tycho's beautiful series of observations led Kepler to seek for a much closer accord between theory and observation than that which he deemed satisfactory in his early researches

Research Items.

Heredity of Polydactyly in Man—An analysis of certain family trees showing polydactyly has been made by O Koehler (*Biolog Zentralbl*, p 705, 1929) He finds that, combining the total numbers of occurrences in the various families concerned, the abnormality has occurred 230 times in men and 188 in women But this result, indicating that men are more subject to polydactyly, is due to the large numbers of males included in the older cases, and is contrary to Snyder's opinion Whatever the incidence of the abnormality may be, it would seem that it is equally heritable through male or female lines, for the numbers of fathers and mothers who passed on the defect were identical, 56 each Should further collections of data show that both sexes were equally capable of handing on the abnormality to their children, although it became manifest more often in males, this would support the view of the author

Variation in Chinese Students—A biometric study, analysing the physical measurements of a fairly representative group of Chinese students, has been made by Ju chi Li (*Peking Soc Nat Hist Bull*, vol 4, p 93, 1930) The data consist largely of physical measurements of male gymnasium students aged between twenty and twenty five and comprise broad aspects, such as height, weight, width, and thickness It was found that the student from northern China was decidedly taller in stature, thicker in chest capacity and heavier in weight On the other hand, the southern Chinese had a slightly longer leg in relation to the total height, and proportionately slightly wider shoulders On the whole, however, the northern type blends so gradually into the southern that it is scarcely justifiable to separate them on geographical grounds, except for such comparisons as are given in this paper Within the individual body various correlations, more or less close, were found, width, for example, depending upon height, and girth upon width Taken separately, the thickness of a person as measured by girth has the highest net correlation, height comes next, and width last So that height ought not to be taken as the sole weight index, a combination of height and girth giving a much closer correlation with body weight

Delayed Development of Embryonic Young in Martens—One of the interesting points noted by F G Ashbrook and K B Hanson in the course of observations upon the normal breeding season and gestation period of martens (*Martes americana*), was that the embryo showed marked delay in development (U S Dept Agr, *Circular* No 10, 1930) Such a delay is unusual, but is familiar in the case of roe deer in Great Britain Martens were observed to mate in midsummer (July and August) On Sept 4 all females were isolated from the males, but the young were not born until April of the following year Although it could not be determined to which of several matings conception was due, the gestation period ranged from 259 to 275 days or from 8½ to 9 months, a period excessively long compared with that of related animals of similar size and similar development at birth Positive evidence of delayed embryonic development is suggested by the observation that female martens trapped and killed in the wild have not shown macroscopic signs of pregnancy until late in winter

Sea Trout of South Uist—Mr G Herbert Nall in his paper, "Sea Trout of South Uist The Howmore, Kildonan, and Loch a Bharp Districts Part 2" (Fishery Board for Scotland, *Salmon Fisheries*, 1929, No 4), supplements his first paper of July 1928 (Fisheries, Scotland, *Salmon Fish*, 1928, 7) Most of the former conclusions are here confirmed and the tables are brought up to date The South Uist sea trout differ from the mainland types in their rapid growth rate, shortness of life and consequently few spawning periods The author again shows that there is no genuine spring run analogous to that of spring salmon, the fishes having almost all wintered in the loch or spent the greater part of the winter there There is no sign of any definite movement from sea to fresh water in February or March, although occasional visits to brackish water may account for the good condition of some of them, and there may be a small interchange throughout the winter between small shoals of fishes from the coast and those from fresh water These sea trout do not remain in fresh water until the following autumn, but have returned to the sea by May Of the marked fish only about 3 4 per cent were recaptured, mostly by the commercial nets

Axial Gradients—Dr Silvio Ranzi in his paper "Embriogenesi e gradienti assiali" (*Memorie della Pont Accademia delle Scienze—i Nuovi lincei*, Series 2, vol 12, 1929) discusses the question of the axial gradients of Child whether they truly exist in the course of embryonic development and regulate the growth, or whether they are the results of the unfolding of the embryo itself He concludes after examining the evidence of many workers in this field that this last solution is probably right, especially in vertebrates, annelids and cœlenterates which have a cephalo caudal or oro aboral axis, and, further, that the facts relating to differential susceptibility to toxic agents may be explained by the greater susceptibility of any organ at its most complex development Dr Ranzi's own observations have been made on the Cephalopoda, especially with regard to differential susceptibility, and he finds that the more complex the organ, the greater the susceptibility to toxic agents and the more easily and deeply are they inhibited He failed to demonstrate in the Cephalopoda the presence of axial gradients in the susceptibility of the blastoderm to toxic agents This paper reviews and criticises the work of various specialists on different groups of animals, ranging from planarians and cœlenterates to vertebrates The general conclusions are (*a*) that in the embryo permeability and susceptibility are greater in those parts which are most complex and are the centres of highest metabolism, but this is limited to the period of development of these parts, and (*b*) with regard to the importance of the principal axial gradients in embryonic development, the principal gradient must be retained as an apparent result of the processes of development according to an axis (vertebrates, annelids, cœlenterates), for along this axis are centres of metabolism, the highest being usually anterior However, the author is of the opinion that the metabolism does not increase or decrease gradually along the axis, but varies from time to time

Tertiary Molluscan Fauna of Waiheke Island, New Zealand—Early in 1927 a Tertiary deposit was discovered at Oneroa, Waiheke Island, near Auckland, New Zealand Collections of the contained molluscan fauna were made and the results are now detailed in a joint paper by A W B. Powell and J A. Bartram (*Trans N Z Inst*, vol 60) The beds seem to have accumulated in small pocket-like hollows worn in the underlying Trias-Jura Greywacke terrain prior to Tertiary submergence. Owing to the large percentage of new species accurate correlation

of these beds with fossiliferous horizons in other parts of New Zealand is very difficult, but the authors give reasons for considering them to be the equivalent of the Hutchinsonian stage of the Upper Oligocene. The fauna is decidedly littoral, or shallow water in character, two species of *Cominella* furnishing the most characteristic members. So far, 78 species have been found, of which five have been referred to recent forms and some 44 described as new. The seventeen plates, if not exactly artistic, give 109 sufficiently efficient figures which would have been more acceptable had the actual sizes of the originals been indicated beside them in some customary manner.

Duration of Eocene Time.—W. H. Bradley describes the varved sediments of the Green River formation (middle Eocene) of Colorado, Utah, and Wyoming in *Prof. Paper* 158 E of the U.S. Geol. Survey. The formation is a series of lake deposits averaging 2000 ft. in thickness. Many of the beds of marlstone, oil shale, and fine grained sandstone are varved, the dominant type being a pair of laminæ, one of which is markedly richer in organic matter than the other. The average thickness of the varves is about 0·18 mm., the range being from 0·014 mm. to 9·8 mm. The interpretation of the laminæ as varves is tested by analogy with modern lake deposits and by calculation of the annual thickness to be expected as judged from the data of present day stream loads. The Green River epoch is estimated to have lasted between five and eight million years. From this and an estimate of the rate of accumulation of the fluviatile deposits above and below the Green River formation the duration of the whole Eocene period is calculated to be between thirteen and thirty three million years. This result is of the same order as that deduced from age determinations of radioactive minerals, but is entirely independent of them. Three cycles of greater length are suggested by fairly regular recurrences of thicknesses and characters: (*a*) averaging a little less than twelve years, probably corresponding to the sunspot cycle; (*b*) about fifty years; and (*c*) about 21,600 years, suggesting the average period resulting from changes of eccentricity in the earth's orbit and the cycle of the precession of the equinoxes.

Aeroplane Survey in Canada.—The use of the aeroplane for transport and reconnaissance in the North West Territories of Canada has rapidly pushed northward for several hundred miles the area capable of development. During the last two summer extensive flights have been made in the Keewatin district to the west of Hudson Bay and in the Mackenzie district. Much preliminary prospecting of the ground has been done in this way. It is claimed that by a study of the country and especially by 'vertical' photographs examined stereoscopically the ground can be classed as promising or unpromising for more detailed investigation. The methods and routes are described in general terms in a pamphlet published by the Department of the Interior entitled "Preliminary Report on the Aerial Mineral Exploration of Northern Canada." Although the Keewatin area was found to be, on the whole, unpromising as regards minerals, a great deal of useful topographical information was obtained.

Settlement in Kenya.—The Agricultural Census of Kenya Colony (Tenth Annual Report, 1929) gives a statistical record of the progress of European settlement. The area occupied by Europeans reached about five million acres, showing an increase over that of the previous year of a little more than two per cent. The number of occupiers rose to 2035, and a further small addition gives a total of 2882 as the number of Europeans, including occupiers engaged on agricultural holdings. The numbers increase slowly and the rate has fallen from 10·37 per cent in 1924 to 3·25 per cent in 1929. Drought during the last two years is no doubt partly responsible. Nevertheless, the cultivated area of the occupied land continues to increase and is now more than eleven per cent. Maize continues to be the principal crop, but wheat has grown in importance. Sisal, hemp, and coffee promise well. A revival in the production of sugar is expected.

An Ice-Telemeter.—The necessity of recording the distribution of ice in waters frequented by vessels of commerce has led Prof. M. Kamienski to invent a simple instrument which he calls an ice telemeter, and which is designed to afford a ready means of measuring the distance of floating ice from the observer. The instrument and its use are described in *Wiadomosci Matematyczne*, Vol. 32, and Report No. 8 of the Astronomical Observatory of Warsaw University. The instrument is a kind of sight rule about half a metre in length. A movable scale at one end is aimed on the ice and the apparent horizon or a distant seacoast. The distance of the ice can then be read on the scale. Experiments over known distances have shown that the telemeter is not absolutely accurate, but near enough to accuracy for the purpose for which it is designed. It is intended for use in light ships and lighthouses of the Polish waters of the Baltic. The theory of the instrument is explained, but only a short summary of the paper is in English; the text is in Polish.

Soil Corrosion.—Corrosion, particularly of the ferrous metals, presents a serious industrial and economic problem, and hitherto the available remedies have been quite impractical. An illustrated article by H. W. Hough entitled "Significant Developments regarding Soil Corrosion" has recently appeared in *The Scientific Monthly*, Feb. 1930, vol. 30, from which it is evident that the study of the subject has advanced materially. The electro chemical theory of corrosion appears to be generally accepted, the rate at which hydrogen is evolved from the surface of the metal being actually proportional to the rate of corrosion. A method of soil corrosion surveys has been developed, in which soil samples are taken at intervals over the country through which a pipe line is to be laid. A topographical survey is also made, the amount of moisture, slope, and vegetation, and any local factors being taken into consideration. From a correlation of these data with the analyses of the various soil samples and their pH values, the degree of corrosive action in each district can be determined. The results obtained from such surveys agreed closely with those of some direct experiments carried out by the U.S. Bureau of Standards in which various metals, both treated with different paints and unprotected, were buried in different types of soil for two or four year periods. No one type of metal proved superior to all others in every type of soil, but it is clear that saving could be effected by a certain selection with regard to soil conditions. The inherent characteristics of the soil, however, are the dominating factors influencing corrosion.

Dependence of Raman Scattering on Frequency.—An analogy between the scattering of light without change in wave-length, and the modified scattering which constitutes the Raman effect, which is in sharp contrast to the general dissimilarity of these two processes, is given by Prof. Ornstein and J. Rekveld in the *Zeitschrift für Physik* for April 24 (p. 593). Quantitative intensity measurements were made on the Raman satellites produced by carbon tetra-

chloride on three strong blue and green lines of the mercury arc (λλ4047, 4358, and 5461) After allowing for the difference in intensity of the exciting lines, it was found that the intensity of a Raman line produced by a definite change in the molecule of carbon tetrachloride was proportional to the fourth power of the frequency of the exciting light, which is the same as Rayleigh's law for unmodified scattering The measurements were not sufficiently exact to decide if the correct frequency to be considered was that of the exciting radiation, or that of the light which had suffered a change in wave length in the scattering process

Single Mirror Interference Fringes with X-Rays —The issue of *Die Naturwissenschaften* for April 18 contains a note by W Linnik, of the State Optical Institute of Leningrad, on the interference of X rays in a Lloyd single mirror apparatus A glass reflecting surface was used, as for the usual optical experiment, but the short wave length of the X rays made it essential to work with a slit source of very small width, and to place it unusually close to the plane of the mirror Details of the experiment are not given, but it is stated that the slit used was only 0 1 μ wide, and that it was 2 2 μ from the mirror Fringes of excellent definition were obtained with a spacing of 5 μ on a photographic plate at a distance of 15 cm from the slit, from which the wave length of the $K\alpha$ radiation of copper has been calculated to be 1 56 ± 0 03 A, Siegbahn's value for this being 1 54 A

The Kata-Thermometer —The applications of this instrument, invented by Prof Leonard Hill, as well as full directions for its use, are set forth in a new pamphlet issued by the manufacturers, Messrs James J Hicks, Hatton Garden, E C 1 The kata thermometer has already proved itself to be the simplest and most useful means for checking the efficiency of ventilating systems and fully deserves its title of 'comfort meter and evaporimeter' The pamphlet now contains a chart from which wind velocity may be quickly derived once the reading of the dry kata thermometer is determined Though absolute standardisation in manufacture is impossible, each instrument is turned out with its own factor, thus rendering calibration by the purchaser unnecessary

Mechanism of Reactions —In a paper in the January number of the *Journal of Physical Chemistry*, by P Robinson, the question of the mechanism of reactions is examined from the point of view of a rule proposed by the author This states that in an isothermal system, where several reactions are possible, that reaction takes place first for which the products have the highest entropy The rule is considered for two typical systems, namely, the sulphur system and the water system, with steam, water, and ice as the possible phases In the latter case it is argued that if steam is brought into contact with excess of ice below the melting point, liquid water is formed before ice, although the reaction to form ice is so rapid that the intermediate liquid phase cannot be observed It is shown that two other rules which have been proposed do not agree with the facts in the case of some transitions in the two systems studied These are Ostwald's rule, according to which that reaction takes place first, the products of which are least stable, and Tantzov's rule, according to which that reaction takes place first which involves the minimum change of entropy The first does not hold when gaseous sulphur above the transition temperature passes directly into monoclinic sulphur without going to the rhombic form, and the second is in contradistinction to the fact that rhombic sulphur below the transition temperature passes directly into vapour without going through the monoclinic form These exceptions are, however, to be expected on Robinson's rule

Dissociation Constant of Water —The value of the dissociation constant of water, $K_w = [H^{\cdot}][OH']$, has been found by the conductivity of pure water, hydrolysis, and the e m f of cells The value found by the first method by Kohlrausch gave $1\ 04 \times 10^{-14}$ at 25°, and this has usually been considered the most trustworthy figure, although other values, such as $1\ 005 \times 10^{-14}$ found by Lewis and Randall by other methods, have more recently been put forward In the March number of the *Journal of the American Chemical Society*, R F Newton and M G Bolinger describe some experiments on the e m f of a cell containing mercurous bromide and mercuric oxide from which they have calculated the value of K_w The result obtained was $1\ 02 \times 10^{-14}$, from which it appears that the value of Kohlrausch is sensibly correct and that the newer values are somewhat too small

Reduction of Carbon Monoxide —Sabatier and Senderens in 1902 showed that a mixture of carbon monoxide and hydrogen when passed over reduced nickel at temperatures above 180° was reduced, with the formation of methane $CO + 3H_2 = CH_4 + H_2O$ Further investigations of the reaction showed that liquid hydrocarbons were also formed in the reaction In three papers in vol 12 of the *Scientific Papers* of the Institute of Physical and Chemical Research, Tokyo, published in February, S Kodama has given a summary of the literature on the subject and has described a number of important experiments on the reduction at normal pressure Various catalysts were used, particular attention being directed to the catalytic decomposition of the monoxide with deposition of carbon With nickel this decomposition did not occur, but it was found with other catalysts

High Tension Testing —Although our knowledge of the behaviour of aircraft during thunderstorms has been increased by reports on cases where they have been struck by lightning, yet there are many technical questions involved which are still difficult to answer The hot exhaust from the engines is doubtless a likely path for the flash The ignition system also may be broken down by the flash and the collapse or building up of a strong electrostatic field in the neighbourhood seriously adds to the fire risk In a paper by A O Austin, engineer to the Ohio Insulator Company, read to the High Tension Congress held recently in Paris, an abstract of which appears in *Engineering* for April 4, an account is given of a novel equipment for open air experiments at electric pressures up to three million volts Several years ago the company recognised that the cost of indoor tests on models at the necessary high pressures would be prohibitive The laboratories have been built to enclose a courtyard one side of which is open and faces the testing ground, which is 1000 feet long and 400 feet wide The high tension equipment consists of three 750 kilovolt transformers of identical types which can be connected in series The bushing of the highest voltage transformer is fifty feet above the ground They have been operated when the crest voltage is well over three million volts It was found that at pressures greater than two million volts it was very difficult to prevent 'flash-overs' from the mains For the artificial lightning tests the transformers charge a very large air condenser By distance control the voltage of the generators is gradually increased until the flash-over at the impulse gap takes place

The Tatem Laboratories at University College, Cardiff

University College, Cardiff, was honoured on May 21 by a visit from H R H the Prince of Wales, Chancellor of the University of Wales, for the purpose of opening the new laboratories of chemistry and physics and inspecting the Advisory and Research Department of Agriculture and the Institute of Preventive Medicine of the Welsh National School of Medicine

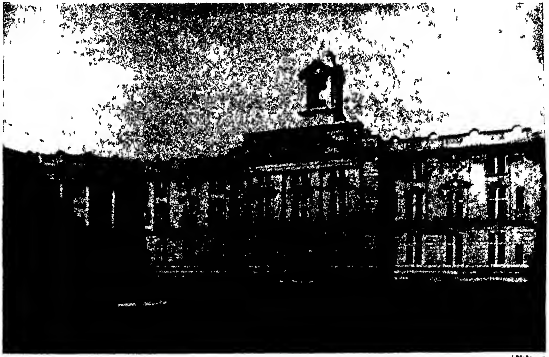
The laboratories of chemistry and physics constitute the north wing of the College buildings in Cathays Park, Cardiff, the civic quarter of the city, which is exclusively devoted to public buildings designed to form an harmonious ensemble Long projected and long delayed by the great rise in the costs of building since the War, these laboratories are the culmination of an effort of local patriotism which the depressed state of industry in South Wales has made trebly difficult Nevertheless, they are only an instalment of the completed plan The arts and administrative sections of the College have been housed upon the Cathays Park site since 1909, but it yet remains to erect the south wing, to accommodate botany, zoology, and geology, which are still in their old quarters in Newport Road, as well as to put up the Great Hall of the College on the fourth side of the quadrangle

The new wing which has been formally opened by the Prince, was designed by Mr W D Caroë, the architect of the main buildings In it, chemistry and physics are accommodated together in close association and in a manner really worthy of the intellectual and industrial importance of modern studies in these subjects

The Department of Chemistry occupies the basement and the first and second floors The first floor comprises a qualitative laboratory for 102 students, a quantitative laboratory for 60 students, two organic laboratories for 60 and 30 students respectively, three balance rooms, combustion room, an electro chemical laboratory, store and service rooms, a library, and staff private rooms

On the second floor are two physico chemical laboratories, a dark room, three research laboratories, a workshop, and two lecturers' rooms The basement, approached by a cart way from the street, provides a store for acids, solvents, and heavy chemicals, with communication by lift to the laboratories and to further capacious store rooms on the upper floors

At the present moment the building of the chemical lecture theatres, preparation rooms, and museum is not being proceeded with, although the foundations of the whole block have been laid



Photo] [Blakeman.

FIG 1 —Physics and Chemistry Laboratories

Special attention has been given to efficient ventilation Each series of fume chambers is independently exhausted by fans to the roof, while the rooms are fitted with a specially designed system of air flues, also connected to a large exhaust fan on the roof Accessibility of water, gas, electric, and drainage services has been secured wherever possible In the larger laboratories, ridge and furrow top lights have been employed, ensuring exclusively north lighting The benches in the large laboratories have been arranged on the island principle and their low superstructures facilitate supervision of large classes

The physics accommodation occupies the whole of the ground floor, with an additional six rooms on a mezzanine floor As the new laboratories communicate directly with the ground and first floors of the Viriamu Jones Memorial Research Laboratories, the Physics Department is now, after many years, once more housed under one roof, with, obviously, very great advantage to all concerned

As in the case of chemistry, the present accommoda

tion represents only a stage in the complete scheme Another wing is to be provided, with a large lecture room, workshop, additional research accommodation, and small laboratories for special research The present building contains a small lecture room and a temporary workshop, which is, however, very well equipped Other small rooms, originally planned for special experimental work, have had to be used for routine work by honours students, as a result of the large increase of the honours school

The greater part of the physics for intermediate and final degree students is accommodated in three large, well lighted rooms, each approximately 30 ft by 50 ft

Photo] FIG 2 —Institute of Preventive Medicine [Blakeman.

Except in the case of the junior laboratory, large, fixed benches in the centres of the rooms have been entirely avoided The essential gas and electric services are led to a series of light posts, about 4 ft high, around which working tables are grouped as required This arrangement, with its obvious flexibility, has proved very satisfactory in practice

The senior electrical work is provided for by two fairly large electrical laboratories These were originally intended to be reserved for final and honours students respectively, but a certain amount of overflow has been inevitable Four darkened rooms are provided for optical experiments and there are smaller rooms for experiments which cannot conveniently be carried out in the general laboratories

Electrically, the laboratories are very well supplied with lighting and power points for 200 volt D C, while 200 volt, 50 cycle alternating current is available also at a number of points The galvanometer lamps are supplied with 12 volt A C, stepped down from the municipal A C supply Steady current for experimental work is derived from a battery of seventy 250 ampere hour accumulators This battery feeds, through a terminal board of special design, 28 points and sub-switchboards in the teaching and research laboratories Any voltage from 10 volts to 140 volts, in steps of 10 volts, can be supplied to any point Large currents over a wide range of voltages can be supplied through the same board, from either a large or a small motor generator, installed in the switchboard room

The building of these laboratories on such a scale was made possible by the generosity of a number of public men in South Wales The chief donors were Lord Glanely, sometime president of the College, and his successor in that office, Sir David Llewellyn, Bart

His Royal Highness was received by Lord Treowen, president of the College, Principal J F Rees, The Hon W N Bruce, Pro Chancellor of the University of Wales, and others He inspected the statues of His Majesty the King and of himself as Chancellors of the University, niched in the College facade, which had been unveiled by Lord Glanely prior to His Royal Highness' arrival Lord Treowen then addressed the Prince, giving a short history of the development of the College and of the progress of its Building Fund Appeal In the course of his response the Prince said "At one time it was generally considered that the chief object of university training was the preparation of students for academic careers, but nowadays the importance of the relation between science and industry is more clearly realised, and we know how valuable a contribution scientific training makes to our commercial and industrial welfare Close co operation between leaders in academic life and the controllers of great business concerns is in the best interests of the country, and from its universities in future will go forth not only the teachers of the generations to come but also—and this is just as essential — young men well equipped by their training to maintain our vital supremacy in commerce and industry"

Lord Glanely then announced that he had decided to increase his benefaction by the sum of £20,000, which would wipe out the debt on the existing building and provide a capital sum for maintenance, while on behalf of himself and Sir William Reardon Smith, he also announced the foundation of three new scholarships The Prince then announced a further donation from Mr Dan Radcliffe, treasurer of the College, of another scholarship and a capital sum of £5000

Finally, the architect, Mr W D Caroë, handed the key to His Royal Highness, who declared the building open Prof H R Robinson (physics) and Prof W J Jones (chemistry) were then presented and accompanied the Prince in his inspection of the Laboratories

Afterwards, a short visit was paid to the Advisory and Research Department of Agriculture, a block at the south end of the main facade of the College, which also owes its existence to the great generosity of Lord Glanely Here there are three floors, containing the offices of the advisors in veterinary science, agricultural botany, and agricultural zoology respectively, together with a large joint Museum and three laboratories, as yet unfurnished, which it is intended to devote to research in problems ancillary to agriculture

In the afternoon the Prince paid a visit to the Institute of Preventive Medicine of the Welsh National School of Medicine in The Parade The foundation

stone of this Institute was laid by His Royal Highness in 1921, on the occasion of his installation as Chancellor of the University of Wales

The present visit enabled Sir William James Thomas, Bart, the donor of the Institute, to hand over the title deeds of the building to the University College of South Wales and Monmouthshire

The Institute comprises four storeys and a basement, and contains, beginning at the top floor, first the Department of Tuberculosis, supervised by Prof Lyle Cummins, the David Davies professor of tuberculosis in the School of Medicine and Director of Research to the King Edward VII Welsh National Memorial (Tuberculosis) Association On the second floor is the Department of Pathology, at present in charge of Dr J B Duguid, the chair being vacant The first floor is devoted to the Department of Preventive Medicine, in charge of the Mansel Talbot professor, Dr E L Collis, who is also Director of the Institute Lastly, the ground floor is occupied by the joint City and County Laboratory of Public Health This is a most valuable feature of the organisation, since it is housed here alongside of the Department of Preventive Medicine and the materials, equipment, and personnel of the public laboratory are available as part of the organisation of the teaching department

The Research Scheme of the Institute of Brewing

If we except the research work carried out with the object of elucidating medical problems, there are no other investigations of so comprehensive a character as those concerned with malting and brewing The problems here presented are connected with biology chemistry, physics, and engineering, and the knowledge gained is of service, not only in the branches of technology for which they are undertaken, but they also find application in many other directions To take but one instance, the study of fermentation has produced results of incalculable benefit to mankind in general, for cannot we trace our present knowledge of zymotic disease to the researches of Pasteur on wine, beer, and vinegar? It is therefore of the highest importance to review the knowledge that is being collected by those who are working under the Research Scheme of the Institute of Brewing, an outline of which is given in the Memorandum for 1930 which was issued a short time ago

An important part of the researches on barley is concerned with the production of new varieties and the Institute is, in this connexion, closely associated with the National Institute of Agricultural Botany, Cambridge, as well as with the Rothamsted Experimental Station, Harpenden and Woburn, nor must we omit to mention the valuable work on barley breeding carried out by Dr E S Beaven The Institute is collaborating with the research staff of the Distillers' Company in tracing the changes that occur in the protein and carbohydrate constituents during the development of the grain and during the malting process The metabolism of the proteins of barley in the germination process is being studied at Rothamsted by Dr R L Bishop, whose results are of far reaching importance and interest to both pure and applied science Manuring experiments on barley and on hops are being carried out and the crops submitted to small scale brewing trials in the laboratory The breeding of new varieties of hops has for many years been carried out by Prof E S Salmon of Wye College Some of the new varieties obtained have been put through brewing trials by well known brewery firms

Methods for determining the brewing and antiseptic properties of hops have been devised by Mr A Chaston Chapman (chairman of the Research Committee), by Messrs Ford and Tait, Prof F L Pyman, Dr T K Walker, and Mr J J Hastings The diseases to which hops are subject are being studied by Prof Salmon and his colleagues Mr A H Burgess is engaged in experiments on the drying of hops, and he has specially studied the processes in vogue at Czechoslovakia

Researches on yeast were commenced at the Imperial College of Science and Technology by the late Prof S B Schryver This work, as well as that on the nitrogenous constituents of wort, which was interrupted by the untimely death of Prof Schryver last year, is being continued by other investigators

The existing methods of estimating starch in barley and in malt are being revised by Prof A R Ling and new methods are being devised This work, it is hoped, will be published very soon Prof Ling is also working on the carbohydrates of barley and malt other than starch

This activity in research, under the able direction of Mr H Lloyd Hind, must commend itself alike to all scientific workers

University and Educational Intelligence

CAMBRIDGE Mr M H A Newman and Mr A S Besicovitch have been reappointed University lecturers in mathematics, Mr W M Smart, of Trinity, and Mr A F Ingham of Trinity, have been appointed University lecturers in mathematics Mr I G Bedford, of Sidney Sussex, has been reappointed University lecturer in physics, and Mr J D Bernal University lecturer in structural crystallography

Mr E B Worthington, of Gonville and Caius College has been elected to the Balfour Studentship

The Vice Chancellor has published a letter from the Universities Bureau of the British Empire in which it is stated that the executive committee of the Bureau has been asked by the Trustees of the Josefine and Eduard von Portheim Foundation to make grants to enable one or more graduates of universities of Great Britain and Ireland to take a post graduate course or undertake research in the University of Heidelberg Preference on the occasion of the first election will be given as between candidates of equal merit to a student proposing to work in mineralogy or crystallography in the Mineralogical Institute founded and directed by Prof V Goldschmidt

New regulations for the Economics Tripos will come into effect next year Under the new scheme, the first part of the Economics Tripos will become a one year course and the second part will, normally, take two years, although candidates coming from another Tripos in their third year will be allowed, if they wish, to take it in one year but with a reduced number of papers The objects of the change are to throw the emphasis more on the second part than it is at present, getting thereby a higher standard of advanced work, and to strengthen the political side by putting in a practically compulsory paper on the principles of politics

LONDON —The following appointments have been made Prof H R Robinson, since 1926 professor of physics at University College, Cardiff, to the University chair of physics tenable at East London College, Dr J W Munro, who has since 1926 been responsible for the control of the Imperial College Biological Field Station at Slough and for the direction there of a research for the Empire Marketing Board, to the University chair of entomology tenable at the

Imperial College (Royal College of Science), Prof P G H Boswell, since 1917 Herdman professor of geology in the University of Liverpool, to the University chair of geology tenable at the Imperial College (Royal College of Science)

The following doctorates have been conferred *D Sc in chemical technology* Mr D M Newitt (Imperial College—Royal College of Science), Mr D T A Townend (Imperial College—Royal College of Science and East London College), *D Sc in chemistry* Mr M Q Khuda (Imperial College—Royal College of Science), *D Sc in psychology* Mr A S J M Huggett (St Thomas's Hospital Medical School), *D Sc in mathematics* Mr R C J Howland

MANCHESTER —Prof J M F Drummond, Regius professor of botany in the University of Glasgow, has been appointed Harrison professor of botany and director of the botanical laboratories in the University on the retirement of Prof F E Weiss Prof Drummond was educated at King's College, London, and at Gonville and Caius College, Cambridge He gained a first class in Part II of the Natural Science Tripos in 1904 and was elected to the Frank Smart research studentship, which he held for two years while engaged on research on photosynthesis with Dr F F Blackman He was appointed as lecturer in botany at Armstrong College, Newcastle upon Tyne, in 1906, and became senior lecturer in plant physiology in the University of Glasgow in 1909 On the establishment in 1921 of the Scottish plant breeding station at Corstorphine, Midlothian he was appointed as its first director, and resigned in 1925 on appointment to the Regius chair of botany at Glasgow While Prof Drummond's botanical interests cover a wide range, his original investigations have been especially concerned with plant physiology and genetics The University already possesses at the Firs in Fallowfield experimental grounds which it is hoped Prof Drummond will be able to develop still further on lines useful to the promotion of horticulture and agriculture

Dr John Walton, lecturer in botany, has been appointed a senior lecturer as from September next

The Council has gratefully accepted the offer of the Manchester Medical Society to present to the University its medical library This library has been housed in the University since 1875, and for a number of years has been supported jointly by the Manchester Medical Society and the University Provision has been made for the members of the Manchester Medical Society to continue their use of the library, and the Society has undertaken to make an annual grant towards the cost of maintenance

At the celebration on May 23 of the jubilee of the University and the eightieth anniversary of the foundation of Owens College, the honorary degree of D Sc was conferred on Prof J Lorrain Smith, professor of pathology and dean of the faculty of medicine in the University of Edinburgh, and Prof A Smithells, director of the Salters' Institute of Industrial Chemistry, London

---

THE Secretary of State for the Colonies will in June and July next award post graduate scholarships in agriculture and agricultural science tenable for from one to two years, and post graduate scholarships in veterinary science tenable for from one to four years The annual value of each scholarship will be £250 plus a certain allowance for expenses Application forms, etc, may be had from the Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1, to whom the completed forms must be returned before June 15

Historic Natural Events

June 1, 1924 Floods—In consequence of heavy rains on the night of May 31–June 1, exceeding four inches in parts of Shropshire and Worcestershire, severe floods occurred in western England Worcester was flooded and the Three Counties' Agricultural Show had to be abandoned

June 2–4, 1666 Abnormal Audibility of Gunfire—On June 2 Pepys wrote "Into the Parke, and there we could hear the guns from the fleete most plainly" But the guns were not heard on the coast, and the yacht *Katherine*, which came into the Thames on that day, heard no firing On June 4 Pepys added "So walking through the Parke we saw hundreds of people listening at the Gravell pits, and to and again in the Parke to hear the guns, and I saw a letter, dated last night, from Strowd, Governor of Dover Castle, which says that the Prince (Rupert) come thither the night before with his fleete, but that the guns which we writ that we heard, it is only a mistake for thunder, and so far as to yesterday it is a miraculous thing that we all Friday and Saturday and yesterday, did hear everywhere most plainly the guns go off, and yet at Deale and Dover to last night they did not hear one word of a fight, nor think they heard one gun This, added to what I have set down before the other day about the *Katherine*, makes room for a great dispute in philosophy, how we should hear them and they not, the same wind that brought it to us being the same that should bring it to them but so it is" This is probably the first definite reference to the 'zone of silence' in the audibility of gunfire

June 4, 1783 Honey Dew—Under this date Gilbert White records ("Natural History of Selborne") "Vast honey dews this week My honeysuckles, which were one week the most sweet and lovely objects that eye could behold, became the next the most loathsome, being enveloped in a viscous substance, and loaded with black aphides or smother flies"

June 5, 1692 Heavy Rain—It is related that the capture of Namur on June 5, 1692, after a siege of only ten days, was largely due to heavy rains which prevented the English army from crossing the river and engaging the besieging French army

June 5, 1784 Thunderstorm—A violent thunderstorm is described in White's "Natural History of Selborne" It began about 2 15, moved from south to north, with convex pieces of ice three inches in circumference which did great damage to windows and tiles At the same time a torrent of rain flooded the meadows, the hollow lane towards Alton was so torn and disordered as not to be passable, rocks being removed that weighed two hundredweight

June 7, 1573 Hailstorm—Between 1 and 2 P M a violent hailstorm broke over Towcester in Northamptonshire, in which six houses were destroyed and fourteen others greatly damaged by floods The hail stones were square and six inches in circumference

June 7–8, 1111 Torrential Rain in Belgium—"On June 7, at the hour of nine, there broke above Robermont (near Liège) three of the blackest rain clouds, which broke very suddenly, so that all was washed away in the city of Liège, it carried off houses, men and women into the River Meuse And the next day, which was Sunday, there came great black clouds which broke over the great church" The lightning did a great deal of damage to the building, and killed a clerk who was reading from the pulpit, and a worshipper who was on his knees praying before the crucifix

June 7, 1692 Earthquake in Jamaica—Port Royal, then the capital of Jamaica, was destroyed by an

earthquake, 3000 lives being lost Three fourths of the buildings in the city and the ground they stood on sank entirely under water Large storehouses on the harbour side were afterwards found 24 48 feet below the sea level A tract of land round the town, about 100 acres in area, sank during the first shock and the sea immediately flowed in

June 7, 1922 Fata Morgana in Hungary — At Nagyhortobagy, Hungary, across a grassy plain with huts, hills, and a well in the distance, all the objects were elevated and in great unrest At several places water surfaces appeared in lively movement with waves moving from west to south west The huts and hills appeared above the water, and then disappeared from time to time A herd of horses driven to the well appeared to advance and then back, and the herdsman and his horse seemed to make an undulating movement, whereas in reality they stood near the well At the time the sky was one third covered with cumulus cloud, and a light wind was blowing from the north

Societies and Academies

LONDON

Royal Society, May 22 —**G H Parker** The ciliation of the Fallopian tubes In the rabbit, spermatozoa travel through the uterus by their own locomotory powers and ascend the Fallopian tube in the main by counter currents (the return flow from the ciliary currents) The eggs press on the ciliated surfaces of the Fallopian tube and descend through this tube chiefly by ciliary action peristalsis may also play a part In the turtle and pigeon the oviduct is lined with cilia most of which beat toward the exterior, but there is also a narrow longitudinal band of cilia which beat toward the ovary and thereby carry spermatozoa to that organ —**D Keilin** Cytochrome and intracellular oxidase Neither component c of cytochrome from yeast cells, a clear solution of deep red colour nor oxidase of heart muscle preparation will oxidise cystein The two together form a powerful catalytic system which can rapidly oxidise cystein The catalytic system thus reconstructed behaves like a true respiratory system of the cell **L E Bayliss, E Boyland, and A D Ritchie** The adductor mechanism of *Pecten* The slow part of the adductor can be isolated from the nervous system in a completely relaxed state in *P magellanicus*, stimulated electrically it gives twitches which can be fused to form tetanus Large tensions are developed In *P maximus* and *P opercularis* different nervous connexions make it difficult to isolate the muscle without some 'contracture', apart from this the muscles are similar to *P magellanicus* The state of contracture is a result of reflex excitation which survives isolation, but may be abolished by direct faradic stimulation Tensions in 'contracture' are much less than the maximum obtainable Reflex movements of intact animals suggest that for the most part the muscle is contracting tetanically The quick muscle with single induction shocks gives a rapid twitch that resembles normal reflex contraction —**H E Roaf** Visual acuity in light of different colours Definition with short wave lengths is less accurate than with medium or long wave lengths That relative intensities, chromatic aberrations, and scatterings of lights can be the whole cause of the observed poorness of visual acuity with short wave lengths seems improbable More likely a lesser density of specific receptors per unit of retinal area is involved With colour filters in front of certain receptors, 'blue' may stimulate only some of them, whilst longer wave lengths can stimulate a larger number per unit area, or the difference might be due to a number of rods being linked to a single ganglion cell, whilst there may be a separate ganglion cell for each cone Evidence is given that the receptors limited to reception of short wave length stimuli are the rods —**Sir Charles Sherrington and J C Eccles** Numbers and contraction values of individual motor units examined in some muscles of the limb Contraction tension for the average motor unit was examined by dividing tension of maximal contraction into number of nerve fibres in the muscle nerve Figures obtained were *gast med*, 30 1 gm *soleus*, 9 9, *semitend*, 5 5, *ext l dig*, 8 6 In all nerves examined analysis of fibre sizes shows two peaks of numerical preponderance, centred on two fibre sizes rather far apart, thus *gast med* 15 μ and 6 μ as measured Of the group of efferent myelinate fibres entering the muscle, many exist several centimetres proximal to muscle, approaching the muscle additional myelinate fibres appear Afferent fibres examined exhibit increase in number as followed in nerve trunk before reaching muscle Approximate estimates of number of motor units composing type muscles are *gast med* 430, *ext l dig*, 330, *soleus*, 250

Royal Meteorological Society, May 21 —**Sir Gilbert T Walker** Seasonal foreshadowing Some applications of the tables of relationships given in previous studies of world weather The southern oscillation affects the winter temperatures of south west and north west Canada as well as the summer rainfall of South Africa and Australia, and the total correlation coefficients found are 0 71, 0 72, 0 72, and 0 79, these would seem to justify prediction in general terms in nearly half the years of a long series —**A C Best** Instruments for obtaining dry and wet bulb temperatures A modified form of the Casella type psychrometer is described in which the aspiration effected by a small electric motor, has the value of 5 metres per second as compared with 1 5 m per second in the usual instrument This psychrometer will run for about eight minutes in air having a relative humidity of 33 per cent before the wet bulb dries up The results of comparing the depressions given by these two psychrometers, two types of sling psychrometers and a Stevenson screen are given

PARIS

Academy of Sciences, April 14 —**Ernest Esclangon** The position of the celestial body at present supposed to be a trans Neptunian planet Application of a parallactic method to observations made at the Paris observatory —**André Blondel** Symmetrical alternators connected with an unsymmetrical network or line —**Léon Guillet and Jean Cournot** Remarks on cold hardening and the annealing of metals and alloys A discussion of two recent communications by Guichard, and by Claussmann and Billon —**F Gonnesslat** The position of the Lowell planet obtained with the photographic equatorial of the Observatory at Algiers —**P Pfeiffer** The operators of a complete system of linear and homogenous partial differential equations of the first order of an unknown function —**Radu Badesco** The distribution of the values of a holomorph or meromorph function —**Elie Cartan** The third fundamental theorem of Lie —**Nicolas Théodoresco** The determination of the velocities as a function of the vortices in the case of a fluid in two dimensions —**Basile Demtchenko** A method of calculation of surfaces of slipping —**P Dupin and M Teissie-Solier** Alternating vortices in non turbulent and in turbulent regime —**F Bordas and E Roelens** Alcoholometric corrections for temperatures below 0° C The range of temperature covered by the experiments was + 15° C to − 30° C —

J Dorfman The magnetic moment of the nucleus of the atom —L Andrieux The preparation of thallium by the electrolysis of its oxides Pure thallium can be prepared by electrolysing its oxides dissolved in boric anhydride (950° C), in alkaline borates (855° 880° C), or in mixtures of borates and fluorides of the alkali or alkaline earths (900° 950° C) —Marcel Chatelet Mixtures of vapours of iodine and of various solvents The absorption spectrum of the gases arising from the vaporisation at 90° C of a solution of iodine in benzene gives an absorption band which belongs neither to the vapour of iodine nor to that of benzene A molecular association is assumed to explain the results —René Dubrisay, René Arditti, and Charles Astier Some transformations produced by the phenomena of absorption —F Vlès and N Kyvelos The spectral properties of the benzoate as a function of the concentration of neutral salts —Jean Cournot The influence of the treatment of steels in solutions of complex phosphates with subsequent varnishing, on their electrical insulating properties —André Courty Tests of casting, under constant pressure, of aluminium and alpax The effects of temperature of the liquid metal, temperature of the mould, and time of heating before pouring were studied separately Jean Challansonnet The dilatometric analysis of some synthetic cast irons with nickel, vanadium, and nickel vanadium These alloys were prepared in a high frequency induction furnace with five metals, and contained 0 08 per cent silicon and only a trace of phosphorus Vanadium raises the temperature of graphite formation of a pure cast iron, it counteracts the graphitising effect of nickel, one part of vanadium annulling the effect of four parts of nickel —Pierre Urbain A quantitative method of spectrographic analysis The method described was designed to deal with quantities of gold of the order of 0 001-0 005 mgm and is based on the simultaneous electrolytic deposition on a carbon rod of the gold and a known quantity of silver This rod is used to obtain spark spectra, and the relative strengths of the silver and gold lines measured with a recording microphotometer —L Palfray and B Rothstein The 1 3 and 1 4 cyclohexanediols Constitution of the halogen derivatives —Jean Thibaud and F Dupré la Tour Study of the polymorphism of the crystals and the orientations of the fatty acids as a function of the temperature From a study of the X ray spectra it is concluded that the saturated fatty acids can be obtained in two principal well defined crystalline forms presenting important differences in their physical properties, especially in the refractive index - Henri Vincienne The structural relations between the Rochers de Léaz (Ain) and the Vieux Chateau d'Arcine (Haute Savoie) and the Vuache Conclusions on the tectonics of this chain —M Loeper, A Lemaire, and A Mougeot The function of the glycogen in the activity of the snail's heart —André Giberton The synthesis of fats in the presence of pancreas extracts —Georges Blanc and J Caminopetros The transmission of the variole of birds by mosquitoes

Rome

Royal National Academy of the Lincei, Feb 2 — Gino Fano Nets of linear complexes of the space S_5 — G Armellini The modern theory of the evolution of the stars Many data based on observation show that, during the first phase of their existence, stars are of great volume, very low density, and intense brightness. The latter diminishes slowly and continuously, and the density increases, whilst the effective temperature of the photosphere, measured spectrophotometrically, rises to a maximum and then begins to fall — C Somigliana The external gravitational field of the ellipsoidic geoid The determination of the lines of force in the field external to the ellipsoidic geoid by integration of the differential equations of these lines is difficult, since the potential function is not harmonic, so that neither Beltrami's ordinary theory of symmetrical potential functions for the case of the ellipsoid of rotation, nor Jacobi's theorem is applicable Various properties of the field may, however, be developed by comparatively simple calculations —U Cisotti Plane electrostatics —A Tonolo Intrinsic form of the equations of the equilibrium of elastic media (1) —R Cacciopolli A question of stability —S Cherubino Observations suggested by a theorem on real Abelian varieties — Rina Baldoni Systems of principal normals to a variety in its π_3 (2) —Pia Nalli Generalised derivations and classification of Riemannian spaces — M Brelot The notion of a point source of heat in a radiating plane in thermal equilibrium —J Geronimus A formula of Tchebycheff —N Théodoresco Steps in a theory of the functions of a complex variable in the general sense (1) —E Gugino The incipient motion of systems with reversible linkings —E Carafoli Theoretical considerations on 'flat spinning' (aerodynamics) — U Barbieri Astronomico geodetic station of Eremo di Cherasco (1) —A Quilico and M Freri A new method of formation of pyrrole blacks One of the most striking facts on which the analogy between phenol and pyrrole is based is the ease with which pyrrole and its homologues couple with diazo compounds This analogy is strengthened by the observation that addition of pyrrole to an alcoholic or glacial acetic acid solution of a diazonium salt, cooled and stirred, results in a very dark, reddish violet solution, which soon deposits a deep black powder resembling pyrrole blacks but, unlike these, almost insoluble in alkalis —R Masini The Rhætic in the Valle della Lima — G B Cacciamali Possible investigations in the subsoil of Lombardy — M Fenoglio Presence of nesquehonite in the serpentine of Viù in Val di Lanzo The possibility of a genetic connexion of the comparatively rare mineral, nesquehonite, with other hydrated magnesium carbonates is considered It is, however, regarded as more probable that nesquehonite is formed at the ordinary temperature and pressure, and that artinite and hydromagnesite are produced at somewhat higher temperature and pressure —G Mezzadroli and E Vareton Action of ultra violet rays on the germination of seeds and on the growth of plants Ultra violet rays of short wave lengths—less than 3000 A — exert a harmful influence on the germination of seeds and on the development of plants At short range, the total ultra violet rays emitted by a quartz mercury vapour lamp exhibit a similar injurious action, even when the exposure is of only brief duration If the seeds and plants are placed at an oblique distance of 50 cm from the lamp, short exposures of 1 5 minutes produce favourable effects, but more protracted exposures, unfavourable effects — M Comel Can strontium be fixed by the tissues? The results of experiments with hens and rats fail to indicate any appreciable fixation of strontium in the tissues

Washington, D C

National Academy of Sciences (*Proc*, Vol 16, No 1, Jan 15) —E S Castle The light-sensitive system as the basis of the photic responses of *Phycomyces* The relation of the 'light growth' response and the phototropic response is investigated by noting the variation of latent period, which is common to both effects, with change of duration of exposure The changes of each response are similar and it is concluded that they have the same functional basis —

H C Ramsperger and R C Tolman The rate of decomposition of nitrogen pentoxide at very low pressures A 45 litre flask was used and a pressure gauge depending on the change of capacitance of a condenser, one plate of which is attached to a mica diaphragm in contact with the gas the pressure of which is to be measured The rate of homogeneous decomposition is of the first order, but when glass tubing is introduced into the reaction vessel to increase the surface, there is a falling off of specific reaction rates —**James A Beattie** A new equation of state for fluids (4) An equation expressing the volume as an explicit function of the pressure and temperature —**George L Clark and Lucy W Pickett** Crystal structures of some derivatives of diphenyl X ray studies of diphenyl, dimesityl and *o* tolidine —**Oliver R Wulf** The temperature coefficient of the photo chemical formation of hydrogen chloride —**E L Nichols and Frances G Wick** Ozone in luminescence Several thermo luminescent substances activated by X rays or cathode rays after treatment with ozone, suffer diminution in brightness Activation by X rays is a reducing effect, when the reduced product is comparatively stable at room temperature but oxidises rapidly and spontaneously on heating, thermo luminescence occurs The effect of ozone is hence due to partial re oxidation —**Paul S Epstein** Geometrical optics in absorbing media A general discussion which has particular significance in the transmission of radio waves in the upper atmosphere —**Edwin H Hall** Recent progress in the dual theory of metallic conduction The numerical results, with recent data, of applying the theory to the relation between electrical conduction, thermal conduction, and Thomson and Peltier effects in eighteen metals, including two alloys —**F S C Northrop** Two contradictions in current physical theory and their resolution A theoretical examination, as a result of which a macroscopic atomic theory is proposed whereby the electrons and protons of the whole of Nature are surrounded by one large finite spherical macroscopic atom Among the consequences are that the universe is finite, there is a physical ether, a new geometry is required, the motion of the microscopic atoms in the macroscopic atom is absolute and the second law of thermodynamics cannot be valid for the whole of Nature —**H E White** Theoretical interpretation of hyper fine structure in singly ionised thallium, Tl II —**Theodore Lyman** The distribution of light intensity in a Fresnel diffraction pattern from a straight edge A diffraction system was illuminated by monochromatic light and intensities registered on a photographic plate measured by a photometer The agreement between theory and experiment are within the limits of error —**Frank Morley and Henry A Robinson** Note on range finding A mathematical discussion for obtaining the co ordinates of the source of sound —**Ernest W Brown** Applications of an expansion theorem to the development of the disturbing function —**Hillel Portisky** On certain polynomial and other approximations to analytic functions —**G A Miller** Groups which admit two thirds automorphisms —**Aristotle D Michal** Differential geometries of function space

Diary of Societies

FRIDAY, MAY 30

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) (Annual General Meeting) at 5 —H A T Fairbank Osteogenesis Imperfecta (Presidential Address)

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts) at 6 30 —H R Ricardo The Development and Progress of the Aero Engine (Wilbur Wright Memorial Lecture)

ROYAL SANITARY INSTITUTE (in Public Halls Blackburn) at 7 —Dr J J Buchan and others Discussion on The Re organisation of Poor Law Hospitals under the Local Government Act

GEOLOGISTS' ASSOCIATION (at University College) at 7 30 —S Hall A Study of the Coastal Geology between Marazion and Porthleven Cornwall (Lecture) —Dr W G Shannon and L G Anniss The Igneous Intrusions of the Stoke Fleming Area South Devon

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir H C Harold Carpenter The Metal Crystal

OXFORD UNIVERSITY JUNIOR SCIENTIFIC CLUB —Dr N K Adam Some Aspects of Lubrication

SATURDAY MAY 31

ROYAL SANITARY INSTITUTE (in Public Halls Blackburn) at 10 45 A M Dr V T Thierens and others Discussion on The Need for Further Legal Powers with Respect to Ice Cream —H W Webb and others Discussion on The Provision and Maintenance of Dustbins—Private or Municipal

MONDAY JUNE 2

ROYAL SOCIETY EDINBURGH, at 4 30 —O F T Roberts On Radiative Diffusion in the Atmosphere —Dr D Jack A Simple Spectrum Comparator —W O Kermack R H Slater and W T Spragg Certain Quinoline and Benzacridine Derivatives yielding Coloured Adsorption Compounds with Iodine —S G Jones A Study of Apothecial Development in the Leaf Spot Disease of Red Clover —E L Ince Tables of the Elliptic Cylinder Functions

ROYAL INSTITUTION OF GREAT BRITAIN at 5 —General Meeting

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College) at 6 —Mrs E Norman Some Observations on the Speech of a Young Child

ROYAL SOCIETY OF MEDICINE (Odontology Section) (Annual General Meeting) (at Royal College of Surgeons) at 8 —Sir Frank Colyer Demonstration on Specimens in the Odontological Museum —C Harborow A Complex Odontome —J G Turner A Histological Report on the Odontome

ROYAL GEOGRAPHICAL SOCIETY (at Eolian Hall) at 8 30 —B Thomas A Journey to the Centre of the Rub al Khali

INSTITUTION OF ELECTRICAL ENGINEERS (Summer Meeting at Irish Centre) (June 2 6)

TUESDAY JUNE 3

SOCIETY OF GLASS TECHNOLOGY (Jointly with Deutsche Glastechnische Gesellschaft) (at Institution of Mechanical Engineers) at 10 A M —Prof W E S Turner A Study of the Chemical Reactions in the Making of Soda Lime Silica Glass —Prof E Zschimmer On the Theory of the Constitution of Glass.—T C Moorshead and E A Coad Pryor Some Experiments on the Cascade Method of Melting Glass —Dr E Berger Influence of Thermal History on the Properties of Glass.—At 2 —Prof W L Bragg The Structure of Silicates —Prof G Gehlhoff Currents and Temperatures in the Glass Tank —H W Howes Volatilisation from Soda Lime Silica Glass —Gehr Reg Rat. Dr A Wendler Development and Trend of the Mechanical Production of Colourless Hollow Glassware

RESEARCH DEFENCE SOCIETY (Annual General Meeting) (at 11 Chandos Street, W 1) at 3 15 —Mrs E Mellanby Diet and Dental Disease (Stephen Paget Memorial Lecture).

MINERALOGICAL SOCIETY, at 5 30 —Dr L J Spencer On a New Meteoric Iron from Piedade do Bagre, Minas Geraes, Brazil —Miss Jessie M Sweet Notes on British Barytes —M H Hey On Face and Zone symbols referred to Hexagonal Axes —Dr L J Spencer Biographical Notices of Mineralogists Recently Deceased (fourth series). —Dr F Walker On a Tholeiitic Phase of the Quartz dolerite Magma of Central Scotland —M H Hey On Pink Epsomites and Fauserite

ZOOLOGICAL SOCIETY OF LONDON, at 5 30 —Dr G C Low D Dewar, T H Newman, and G A Levett Yeats A Classification of the Original Watercolour Paintings of Birds of India by B H Hodgson, S R Tickell, and C F Sharpe in the Library of the Zoological Society of London —P E P Deraniyagala Testudinate Evolution — Margaret C Stean The British Museum Collection of Amphibia from the Middle Coal Measures of Linton Ohio U S A —A Girgis The Development of the Heart in the Rabbit —Dr G S Sansom and Dr J P Hill Observations on the Structure and Mode of Implantation of the Blastocyst of Cavia —Agnes E Miller Note on the Tail Skeleton of *Lepidosiren paradoxa* with Remarks on the Affinities of *Palaeospondylus*

LONDON NATURAL HISTORY SOCIETY (at Winchester House) at 6 30 — E R Taylor The Pyramids and the Sphinx

ILLUMINATING ENGINEERING SOCIETY (Annual Meeting)

WEDNESDAY, JUNE 4

PHYSICAL AND OPTICAL SOCIETIES (Joint Discussion on Photo electric Cells) (at Imperial College of Science and Technology), from 3 to 5 30 —Prof H S Allen The Early History of Photo electric and Selenium Cells (Introductory Lecture)—Dr N R Campbell A Theory of Selective Photo electric Emission with Special Reference to Thin Films of Caesium on Silver —D H Loughridge The Manufacture of Photo electric Cells and their Use in Sound Reproduction —T W Case (a) The Thalofide Cell (b) Barium Photo electric Cells —P Selényi The Manufacture, Properties and Use of Sodium Photo electric Cells —J Kunz Photo-electric Cells and Some Applications — Major C E S Phillips The Manufacture of Selenium Cells —From 5 30 to 7 Demonstrations

FARADAY SOCIETY (at King's College) at 5 30 —Prof T H Laby Quantitative and Qualitative Analysis by X Rays —J T Calvert The Determination of Potassium in Soil Samples by the Application of an X Ray Method

THURSDAY, JUNE 5

PHYSICAL AND OPTICAL SOCIETIES (Joint Discussion on Photo electric Cells) (at Imperial College of Science and Technology) from 10 30 to 1 —Dr N R Campbell The Standardisation of Photo electric Cells Dr N R Campbell and L G Stoodley Time lag in Gas filled Photo electric Cells —E B Moss A Complete Electrostatic Method for the Measurement of Photo electric Currents —Prof G M B Dobson and D S Perfect A Method of Comparing Very Small Amounts of Light by Means of a Photo electric Cell and a Valve Amplifier —N L Yates Fish A Theoretical Investigation of the Use of a Photo electric Cell with a Valve Amplifier —H A Thomas A Theoretical Study of the Amplification of Photo electric Currents by Means of Thermionic Valve Amplifiers —H Geffcken and H Richter Distortion in the Amplification of Photo-electric Currents and a Remedy —Prof G M B Dobson A Spectrophotometer for Measuring the Amount of Ozone in the Upper Atmosphere —D S Perfect A Method of Measuring Small Angles —C H Sharp Notes on Photo electric Photometry —T H Harrison The Photo electric Cell as a Precision Instrument in Photometry —From 3 to 5 30 —Drs W R G Atkins and H H Poole On the Photo electric Measurement of Daylight —Drs J H J Poole and H H Poole The Neon Discharge Tube Photometer —P P Koch Die Photoelektrische Zelle als Hilfsmittel der Registrier photometrie —E A Baker Some Factors Affecting the Speed of the Koch Micro photometer —K S Gibson The Use of the Photo electric Cell in Spectrophotometry —D S Perfect Spectrophotometric Absorption Measurements —H D Griffith Photo electric Photometry in Relation to Phototherapy —V E Shelford The Use of Photo electric Cells in Biological Work

CHEMICAL SOCIETY at 8 —A W Chapman The Influence of a Soluble Fluoride on the Corrosion of Iron —G B Harrison The Application of a New Type of Triode Valve to the Determination of Hydrogen Ion Concentration with Glass Electrodes —E H Farmer and T N Mehta Properties of Conjugated Compounds Part X Variability in the Mode of Ester addition to Butadiene Esters and Ketones

FRIDAY JUNE 6

GEOLOGISTS ASSOCIATION (at University College), at 7 30

SATURDAY, JUNE 7

GEOLOGISTS ASSOCIATION (June 7 to 10) (at Star Hotel Helston).—A Study of the Coastal Geology between Marazion and Porthleven, Cornwall

PHYSIOLOGICAL SOCIETY (in Physiology Department, Edinburgh University)

PUBLIC LECTURE

THURSDAY, JUNE 5

INSTITUTE OF PATHOLOGY AND RESEARCH ST MARY'S HOSPITAL, PADDINGTON) at 5 —Prof G E Gask The Value of Radium in Surgery

CONGRESSES

MAY 28, 29 30, and 31

SOUTH EASTERN UNION OF SCIENTIFIC SOCIETIES (at Portsmouth)

Friday, May 30 at 10 A M —H Dewey Cornish Geology and Scenery, with a Few Remarks on the Isle of Wight by Way of Comparison

At 11 A M —Lt Col J H Cooke, Origin of Scenery in the Portsmouth District, Geologically Considered

At 12 noon —Prof L S Palmer Recent Geology of the Portsmouth District

At 10 A M —J F Marshall The Organisation of Mosquito Control Work

At 11 A M —Miss G F Selwood Observations on Fauna Changes in a Bog at Bembridge, I W

At 8 P M —L R Benny Progress in Astronomy

Saturday May 31, at 10 A M —G E Hutchings Some Applications of Regional Survey in Education.

At 10 45 A M —A Farquharson A Regional Survey of Chichester

At 11 30 A M —D H Thomson Springs, Streams, and Wells in the Portsmouth District

JUNE 3 TO 5

INSTITUTION OF GAS ENGINEERS (Annual General Meeting and Conference) (at Town Hall Leeds)

C F Broadhead The Preparation of a New Road Binder

Dr Margaret Fishenden Heat Transmission with Particular Reference to Modern Methods of Expressing Convection Data.

Dr E W Smith Gas Dehydration

F G Stewart The Functions of Coke Ovens

F Prentice Experiences with a Waterless Gasholder

W H Hoffert and G Claxton Benzole Recovery with Particular Reference to Gas Works Practice

JUNE 4 TO 9

ROYAL INSTITUTE OF PUBLIC HEALTH (at Portsmouth)

Thursday, June 5 from 9 30 A M to 1 —Prof H R Kenwood The Reduction of Preventable Disease—A Few Observations Thereon

D Aulland and others Discussion on National Health and the Local Government Act of 1929

Dr C F White Plague Prevention in English Ports

S Cade Radium and Cancer Clinics

Prof R J A Berry Heredity in Relation to the Nation's Problem of Mental Deficiency

H C M Williams Port Administration

Prof Sir Thomas Oliver The Health of the Worker of To day

Dr W Hanna and others Discussion on Health in Sea faring Occupations

Dr W J O Donovan Occupational Skin Diseases with Special Reference to Cheiropompholyx

F G Bowen Some Geographical and Anthropological Factors in the Study of Industrial Diseases.

Dr A W Sanderson The Health of Women and Girls in Industry

Lady Keyes The Voluntary Worker in Relation to the Public Health Service

Dame A Louise McIlroy and others Discussion on The Prevention of Sickness and Death in Motherhood

Dr I Dorothea Taylor The Health of the School Child

Dr M Critchley The Problem of the Epileptic Child

B Purse The Care of the Blind Child

Col R K White Post Puerperal Disabilities in Women

Sir Henry Gauvain Sun Treatment in England

Dr H M Davies and others Discussion on The Present Position of Surgical Treatment of Pulmonary Tuberculosis

Dr J Gravesen The Early Phases of Tuberculosis and their Treatment

O Amrein The Development of Pulmonary Tuberculosis and the Differential Diagnosis

Thursday June 5 from 10 A M to 1 —Surg Rear Admiral H C Whiteside Some Problems Old and New of the Seafaring Doctor

Major H S Blackmore Points of Contact—The Medical Officer in Charge of Effective Troops links up with the Regimental Officer

Major H N Stafford The Service Doctor and Medical Science—His Contribution

Surg Capt F C B Gittings Has the Naval Service any Ophthalmic Sequels?

Major D T Richardson Experimental Work on Three Types of Stretcher Slings

Prof R Crochet Post Encephalic Parkinsonism and Military Pensions

Friday June 6 from 9 30 A M to 1 —Dr C K Millard and others Discussion on The Slum Problem

Dr C O Stallybrass Variations in Virulence during the Course of Epidemics

Col R J Blackham Acid Milks in Health and Disease

Brig Gen J Charteris The Design and Requirements of Slaughter houses

A Moore Hogarth The Rat Menace

W Buckley National Health and our Milk Supply

Surg Commdr H D Drennan and others Discussion on The Health of Dockyard Workers

Dr H M Vernon New Methods of Heating Buildings and their Influence on Comfort

Dr R E White Sensitisation of the Skin

Dr Letitia D Fairfield and others Discussion on The Slum Child

Miss Doris M Odlum Home and the Adolescent

W Clarke Hall The Problem of the Delinquent Child

Miss B M Johnson The Hygiene of the Domiciliary Labour Room

Dr Olive B Sharp Ante Natal Treatment in Connexion with Venereal Disease

Dr J Watt The Provision of Institutional Treatment for the Tuberculous

Dr R R Trail The Results of Sanatorium Treatment Immediate and Ultimate

Dr Rollier The International Factory Clinic for Indigent Patients suffering from Surgical Tuberculosis

Friday June 6, from 10 A M to 1 —Squadron Leader A F Rook Sanitation in Desert Operations

Surg Commdr J A O Flynn The Control of Malaria at H M Naval Base, Singapore

Surg Capt. L M Morris Recruiting—Review of Modern Requirements.

Wing Commdr H A Treadgold The Conditions of the Heart found in Recruiting

Dr G C Low Climatic Bubo—Its Diagnosis and Treatment.

Science and Philosophy

THE suggestion made by Prof F G Donnan in a letter which appears in our correspondence columns this week, that workers in natural science and philosophy should somehow be brought together in order to elucidate and discuss those fundamental problems with which both are concerned, will, we believe, be given careful consideration over a wide field of thought During the past twenty five years mathematicians and natural philosophers have been led to deal with problems of an essentially philosophical character, while purely philosophic workers from their side have been tending more and more to concentrate attention upon those same problems and to attempt to prepare the way for a more adequate solution of them Most of the really fruitful work in philosophy during the present century has been devoted not to elaborating great speculative systems, but to careful detailed research upon such specific problems as the nature of sense data and their relation to physical entities, the character of space and time in their relation to one another, the basis of scientific induction, the interpretation of life, the relation of mind to Nature, and so on This has been the case not in Great Britain alone, but also on the continent of Europe, as, for example, in the extremely valuable work that has emanated from Husserl and his pupils, one of the most original of philosophic thinkers in Germany at the present time

It is obvious that one of the chief difficulties in all such investigation is that it is impossible nowadays for any one individual to be an expert in more than one or two of the various departments of knowledge upon which the problems referred to touch Few things would be more helpful to the advance of philosophic thought at the present juncture than a combined effort on the part of men of science and workers in philosophy to face the issues which from both sides are being forced upon human reflection The old hard and fast distinction between science and philosophy can no longer be sustained, and the time has come when it should be explicitly recognised that philosophy is, in truth, a branch of science

It is being more and more widely recognised that on one hand the predominantly classical tradition in itself is seriously inadequate to modern tendencies, while, on the other, the difficulties arising from the steadily increasing scientific specialisation are patent Science is being compelled, merely by its own incessant expansion, to investigate its ultimate basis This is pre eminently a philosophical problem of the most intricate order, while the indispensable specialisation practically excludes

the requisite acquaintance with the governing philosophic principles and methods The conclusion seems obvious that research must be complementary, and also systematically directed so far as this is possible without interfering with individual initiative It is well to remember that Aristotle was both a great scientific pioneer and a great metaphysician

The progress of physical research in the early years of the twentieth century had a profound effect on the minds of both scientific workers and philosophers The implication of the theories of relativity and quanta, particularly in relation to notions of space and time, brought the physicist and the mathematician into the realms of philosophy The excursion was not popular Many scientific workers felt alarm and discouragement at the tendency of physical science towards metaphysics, they feared that the doubt and obscurity which have characterised much of the metaphysics of past centuries would invade their science

Among the philosophers there was a movement to grapple with the new problems presented by experimental philosophy Thus we find Prof H Wildon Carr publishing a work entitled "The Scientific Approach to Philosophy" (1924), in which he sets forth his views on the relation of science to philosophy, adopting the view that the fundamental distinction is that, whereas philosophy seeks to see reality as a whole, science is more concerned with particulars, proceeding to laws rather than to a systematic whole Mr Bertrand Russell, on the other hand, believes that the subject matters of science and philosophy are identical and both start from the same point but proceed in opposite directions Prof A N Whitehead, who is also mathematician and philosopher, has formulated a philosophy of Nature through the study of the history of science Only within the last few days a work in which physical science and philosophy are combined, by another pioneer investigator and thinker, has reached us We refer to Sir Oliver Lodge's "Beyond Physics", which aims at the beginning of a philosophical outlook which shall include a basis for life and mind of a physical, though non material, character

This work may be taken as an example of the change which has come over positive science during the past quarter of a century or so, referred to by a reviewer in a notice of Prof Dotterer's "Philosophy by Way of the Sciences" in Nature of April 5 'Not less striking", he remarked, after indicating the changes in the pursuit and teaching of philosophy, "is the changed attitude of men of science, their modified faith in mechanistic explanations of life, and especially of the life of man, their consciousness that every line of scientific inquiry leads to problems which (using the word physics in its older and more general sense) are beyond physics, that is, are metaphysical Hence the present position, that some of our leading men of science are also among our leading philosophers"

Conditions thus seem to be favourable for a closer *rapprochement* between science and philosophy, with the double purpose of working out a real philosophy of Nature and of undertaking a critical overhaul of scientific concepts, perhaps more especially in the biological field Whether at the moment much would be gained by an international meeting devoted exclusively to questions of the relations between science and philosophy is, however, doubted by representative workers in both fields There is a feeling that the common basis of the two groups would be found to be disappointingly small, and that in the absence of sufficient mutual understanding the outcome would be more disruptive than unifying Long range discussion in separate scientific and philosophical journals, and interchange of views between men of science and philosophers at their respective congresses, are helpful in presenting the different points of view, and their extension would be welcomed When the different workers find themselves in the same field they will naturally desire to join in periodical meetings or conferences to consider promising lines of development

At the meeting of the British Association in South Africa last year, General Smuts and other philosophers spoke on questions of interest to both men of science and philosophers, and one of the subjects to be discussed at the International Congress of Philosophy, to be held in Oxford next September, is the question of the metaphysical importance of recent advances in physics As General Smuts is to be the president of the British Association at the centenary meeting in London next year, we suggest that a small joint committee might be appointed representing the British Association, the British Institute of Philosophical Studies, and the Aristotelian Society, to draft a programme of appropriate papers for discussion during the meeting There is at present no Section of the British Association devoted to what may be called scientific philosophy, but philosophic minds are to be found in all the Sections, and it should be possible to arrange a special meeting for the discussion of the basis of all knowledge Perhaps someone will bring the matter forward at the International Congress of Philosophy with the view of getting a joint committee appointed to effect the co operation desired, whether through a periodical international assembly or otherwise

Is Humanism Dead?

Publii Ovidii Nasonis Fastorum Libri Sex *The "Fasti" of Ovid* Edited with a Translation and Commentary by Sir James George Frazer Vol 1 *Text and Translation* Pp xxxi + 357 Vol 2 *Commentary on Books I and II* Pp v + 512 Vol 3 *Commentary on Books III and IV* Pp v + 421 Vol 4 *Commentary on Books V and VI* Pp v + 353 Vol 5 *Indices, Illustrations, Plans* Pp xiii + 212 + 95 (London Macmillan and Co, Ltd, 1929) 5 vols, 126s net

AMONG other fashionable revolts of to day, our reaction against the classics is perhaps a minor, but a vexatious and disruptive crisis, which, while it affects primarily education, also enters deeply into our whole cultural outlook The radical spirits of the day are definitely anti classic The conservative tendency, on the other hand, still leads many thinking people to affirm that no man of science or sociologist has ever rivalled Aristotle, no thinker reached the heights of Plato, and that no philosopher is more worth studying than Democritus, Thales or Anaximander People also still speak of the absolute necessity of memorising Latin cases or of conjugating Greek verbs in order to understand the working of human speech or to acquire the faculty of logical thought This of course is an untenable line of defence of a cause not altogether lost

The grip of dead tongues on the study of language is and has always been pernicious The habit of framing all our linguistic conceptions and grammatical categories on a language which we never can use in its principal function—of living speech between living people and in a living culture—has made philology lose touch with real life and become a barren discipline Again, it is but an affectation to treat the scientific and philosophical work of classical writers as anything but wonderful documents of a past culture As direct contributions to modern scientific knowledge they are obviously worthless

Yet all sane people have an uneasy feeling that it is impossible to dispose thus lightly of humanism We cannot sweep away the influence of classical antiquity on our own culture Nor can we banish philological methods from our schools, our philosophies, our social sciences—any more than we can drop the influence of Greek or Latin on our vocabulary and grammar Classical antiquity has become an essential part of our civilisation—a living myth upon which our culture is built For every culture has to rely upon a retrospective vision, a grand illusion of a Golden Age, lawgiving and inspiring, supplying the present with a life drawn from the past

The historical myths of our own civilisation are the belief in the divine inspiration of the Jews, in the Olympic beauty and wisdom of the Greeks, in the political majesty of Rome as the fountain head of law and statecraft The fact that some of us have come critically to doubt whether Greek sculpture is more perfect than Japanese decorative art, or to suggest that the Indian epics might equal Homer, or that the social and political systems of China are as worthy of study as those of Rome, will never change the fact that emotionally we find our 'promised land' around the eastern basin of the Mediterranean, that somehow Athens, Rome and Jerusalem have acquired a dominance over our emotions as well as over our thought

The anthropologist above all must believe in the continuity of tradition, and whatever defects our classical tradition has, it cannot be jettisoned Classical interests must and will receive ever-widening scope and an increasingly greater depth through constructive criticism Our knowledge of Greece and Rome must be placed within the context of other cultures In this sense, humanism, as living mythology and inspiring science, is not dead and never will be

If we define, then an anthropologist as one who passionately loves the continuity of tradition and works for its preservation and development, who also brings to this task a profound knowledge of our own mythology as well as of the superstitious of other savages—Sir James Frazer is the greatest anthropologist of our age He is also one in the long line of succession of great humanists For, constantly reshaped by criticism from within and without, humanism has, in fact, grown from a narrow and rigid discipline to that all embracing vision of humanity as a whole which, in Great Britain and this generation, has given us the works of Jane Harrison, Gilbert Murray and James Frazer The five volumes of the "Fasti" which mark Frazer's return to applied anthropology and to first hand classical research and reinterpretation, naturally provoke these reflections

The earliest humanists who awoke to the reality of Greek and Latin civilisation from the dead grip of medieval scholasticism and Church tradition, regarded ancient writing and ancient art as a revelation unto itself When, through the discoveries of comparative Indo European linguistics, the scope was widened, we were shown that,

through the sacred books of the East, and through the comparative study of Sanskrit and Zend, Celtic and Slavonic, a new meaning could be given to the religious conceptions of Greek polytheism, to the institution of the Mediterranean patriarchal household, and to the legal norms and historical vicissitudes of the Hellenic and Italic peoples But it was only by placing Latin and Greek culture in the widest comparative survey that the full humanistic meaning could be given to all that is beautiful, and all that is crude and barbarous, in customs and beliefs revealed to us by Virgil and Ovid, Homer and Sophocles

In this work of revealing to us the full human meaning of Greek and Latin culture, Frazer started with his classical interests The six volumes of his "Pausanias" give us a vision of ancient Greece as it was in the times of Imperial Rome In his "Golden Bough", starting from one of the most inexplicable and barbarous customs recorded from Latium, Frazer gives us the theory of primitive culture and of the rational savagery of human faith, a theory which will for ever remain a masterpiece of comparative anthropology Then the great Cambridge scholar, casting himself for a time completely adrift from his Mediterranean moorings, explored the remote continents of Africa, Australia and the New World, discovering the real nature of totemism and exogamy, interpreting, in the "Worship of Nature", the relations between primitive man and his environment, giving, in the "Belief in Immortality and the Worship of the Dead", a new insight into the desire for survival, and, mindful of another 'promised land', he analysed folk lore in the Old Testament, with an insight into Semitic spirit and culture only rivalled by his Greek and Latin scholarship

Now, again, in the "Fasti" of Ovid, he returns to his original interest, and in the running commentary to the poetic version of the Roman calendar, shows once more the kinship between ancient classical belief and that of humanity at large In the first volume we are given the Latin text and the translation, characterised by Frazer's accuracy and learning, as well as by his sense of beauty both in English and Latin But, as we read it, there arise at every step those queries and enigmas which not even the best translator can overcome in a direct rendering Indeed, Frazer needs three bulky volumes of comments to his short half volume of translation But these volumes are not merely a commentary on Ovid and his Roman calendar, but on the whole life of the Roman nation For a pious and practical people like the Romans marked down in their programme of the year, besides historical and legendary landmarks, also dates of religious or magical importance, days of economic or political significance, festivities which affected the family, the city, and the State Thus a great deal of Roman civilisation, projected along the weeks, months and seasons, unrolls before the reader in its yearly sequence

Right from the beginning we are brought to the heart of the real interests which led man to systematise his times and occupations and wed them to the regular courses of sun, moon, and seasons Frazer comments on the 28th line of the poem, in which Ovid accepts the traditional version attributing to Romulus the institution of a ten months year So absurd did this legend appear to some scholars that no lesser a man that Joseph Scaliger and his much younger confrère G F Unger rejected it as a mere fallacy of crude folk lore Anthropology, however, not only endorses Ovid in his fabulous sources, but also can give us a full explanation of the apparent irregularity Frazer is able to show that an incomplete year, based as a rule on lunar divisions, is found all over the world, in defiance not merely of theoretics of the ten months year, but also of the innumerable theories given in explanation of this anomaly This shortened year is due simply to the fact that the real interest of an agricultural people is directed towards what happens on the surface of the earth and not on the vault of the heavens The calendar is determined by the cultivation of fields and the growth of crops, and not by the abstract rotation of stars and constellations Even in the counting of time humanity crawls on its belly, scarcely aware of what passes above and around

Line after line we follow the vagaries of Roman time reckoning, and of Ovid's explanations We learn about the widow's mourning, and about the unlucky periods of intercalary days and months We are led into an analysis of primitive licence, and of the annual mock kings This last subject leads us near to the theme of "The Golden Bough", to which the present book contains, incidentally, a great many riders and additions Especially interesting is the long commentary (vol 3, p 72) to the lines

"The strong of hand and fleet of foot do there reign kings, and each is slain thereafter even as himself had slain"

It would be quite impossible to give point for

point the gist of the many illuminating comments—some brief and pithy, others leading us far afield over the surface of the earth and into the ramifications of a belief or custom, but all pertinent and illuminating, all characterised by that solid grip on fact, by that reluctance to vague theorising, which are the greatest qualities of Frazer's work.

We acquire a great deal of comparative knowledge about the Latin divinities, Janus and Jupiter, Vesta and Juno; about the Lares and other family gods; about Roman family law and its Latin sources and the constitution of the household; about the Sacred Fire, beliefs concerning cross-roads, werwolfs and vestal virgins.

The fifth volume illuminates the learned body of the work with diagrams and illustrations, in the choice of which the author reveals himself again as a scholar and an artist. It also contains an excellent index.

Frazer, who, since the recent publication of this book, has given the world two more volumes on such widely different subjects as the logic and thought of Plato and the myths of the origin of fire, has demonstrated once more the vigour and fertility of the new science and of its master. Perhaps the highest praise that can be given the work under review is that it forms an indispensable compendium to "The Golden Bough", to which it constantly refers, and of which it is a worthy illustration and amplification.

B. MALINOWSKI.

Space and its Properties

The Size of the Universe: Attempts at a Determination of the Curvature Radius of Spacetime. By Dr. Ludwik Silberstein. Pp. viii + 215. (London: Oxford University Press, 1930.) 10s. net.

DR. SILBERSTEIN'S monograph is concerned with the hypothesis, now widely favoured, that space is not infinite, but is a closed domain analogous to the surface of a sphere. Besides giving a general account of this theory, it includes an exposition of certain views which have led him to an estimate of the 'radius of space' much smaller than the estimates of other writers. Whatever reservations we may wish to make with regard to this controversial part of the work, the book as a whole can be cordially welcomed. It is written lucidly, vividly, and with keen flashes of insight. It can scarcely be read by a non-mathematical reader; but the mathematician is not delayed with details, and is guided quickly and racily to the interesting results. The style of expression brings to mind vividly its enthusiastic and impetuous author. The reader may not always agree, but he will enjoy disagreeing with so ingenious an advocate.

Silberstein rejects the spherical world of Einstein and adopts that of de Sitter. This is in accordance with general current opinion; and in any case de Sitter's is the better working hypothesis, since it is the one which has interesting astronomical consequences. Whilst agreeing with his choice, we cannot agree with the reason on which he lays most stress. He seems to regard it as a blemish of Einstein's world that its equations do not admit of the insertion of a particle of matter (a mass centre), whereas de Sitter's admit it. But, when examined, this superiority of de Sitter's world is found to arise from the fact that it is entirely empty; the insertion of a gravitating particle does not upset its equilibrium because there is nothing to upset. When de Sitter's idealised conception is modified into a practical astronomical universe, this supposed advantage is the first property to be discarded.

It is a feature of de Sitter's world that every particle appears to be repelled from the observer with an acceleration proportional to the distance, so long as the distance is small compared with the radius of space. (The law of acceleration at large distances depends on the definition of distance adopted.) In consequence of this, the symptom of world curvature that has been looked for by most authorities and used as the basis for estimating the size of the universe is a velocity of recession of distant objects increasing with the distance. This effect is shown markedly by the spiral nebulæ, which are the most distant objects known. Silberstein differs from everyone else in taking the symptom to be an increase of average speed with distance, irrespective of whether the motion is receding or approaching; he uses for his material star clusters and even stars, which have no marked preponderance of receding velocities. In considering this divergence, it must be borne in mind that we know only the present velocities of celestial objects, and it is, of course, impossible to say that a particular instantaneous distribution of velocities is irreconcilable with any assumed field of force. The most we can do is to connect the field of force and the velocity distribution by some plausible theory of the origin and development of the present state of affairs. We have not space to describe Silberstein's claim to plausibility; it is ingenious but we do not find it convincing.

Some months ago Dr Silberstein caused a mild sensation by announcing a radius of the universe so small that it left the astronomer scarcely room 'to swing a cat in' This calculation is given by him in an appendix, it gives a mere 2,000,000 parsecs for the radius of space (The nearest spiral nebula is distant about 300,000 parsecs) The result depends on stellar motions only We naturally object that inasmuch as world curvature obviously does not explain the main features of stellar motions, it is unreasonable to suppose that it is the only effect to be considered in interpreting their minor correlations In fact, the phenomenon attributed by Silberstein to space time curvature appears to be one which is more usually ascribed to galactic rotation His older value used in the main part of the book was eighteen times greater, and it demands considerable mental agility on the part of the reader who wishes to review the arguments in accordance with the reduced scale

Three years ago a very substantial advance in this subject was made by Abbé G Lemaître (*Annales de la Société Scientifique de Bruxelles*, April 25, 1927) Until recently, this paper seems to have been almost unknown, and we can scarcely blame Dr Silberstein for being unaware of it, but it is unfortunate that the new point of view does not appear in his book In particular it renders obsolete the contest between Einstein's and de Sitter's cosmogonies We can now prove that Einstein's universe is unstable The equilibrium having been disturbed, the universe will progress through a continuous series of intermediate states towards the limit represented by de Sitter's universe By Lemaître's analysis the history of this progress can be studied, and the intermediate stages (one of which must represent the present state of the world) can be treated in detail

A S EDDINGTON

Classification of the Octopoda

A Monograph of the Recent Cephalopoda based on the Collections in the British Museum (Natural History) Part 1 *Octopodinæ* By G C Robson Pp xi + 236 + 7 plates (London British Museum (Natural History), 1929)

IN the present volume, the first instalment of a systematic account of the recent Cephalopoda, Mr G C Robson has attacked the most difficult part of the work—the classification of the subfamily Octopodinæ, the largest division of the order Octopoda The difficulty of classification is enhanced by post-mortem changes which modify or efface the sculpture of the skin and distort the shape of the body and head, by the amount of material available for the study of a single species being generally limited, and hence the amount of variation of the species unknown, and by the defective descriptions of earlier workers, which are often based on more or less valueless characters The author directs attention to the need for intensive studies on the variation of a single species carried out on living examples, and gives the results of an examination of a number of characters in twenty one specimens of *Octopus vulgaris*

A brief description of the structure of the genus *Octopus* deals especially with the features which are important in classification and is followed by a short account of the habits and a note on the characteristics of young forms

In his remarks on phylogeny and classification, the author states that the sub family seems to be broken up into a large number of disconnected and often monotypic groups rather than along well defined lines of evolutionary significance He has, however, reviewed the evidence with the object of obtaining indications as to the characters of the primitive Octopodine, and concludes that these were—rather short, equal arms, a low equal web, probably a W-shaped funnel organ, numerous gill filaments, a small undifferentiated hectocotylus, simple rhachidian teeth on the radula, a superficially placed ink sac, and a widely open mantle aperture

The Octopodine species which have been adequately described fall into the genus *Octopus* (with five sub genera) and eight other genera For these species tables of measurements and other details—in most cases of thirteen characters—are given This is followed by the systematic account in which each genus is defined, the type species designated, and remarks added on matters of historical import For each species the synonymy is given, the locality of the type specimen is stated where this has been traced, a note of the specimens examined, a statement of the known distribution, a description and remarks are added A list of sixty seven insufficiently diagnosed species of *Octopus* is appended, and a brief account added of three species of uncertain generic position A bibliography and an index—both adequate—complete the text

The author is to be congratulated on his method of handling a very difficult subject, which has involved much detailed work and careful analysis and consideration

Our Bookshelf

Recollections of My Youth By Ernest Renan Translated by C B Pitman Pp xlvi + 360 + 2 plates (London George Routledge and Sons, Ltd, 1929) 7s 6d net

THIS new edition of Renan's second most famous book has the great additional advantage of an introduction by Dr Coulton It may well be, as Dr Coulton suggests, that these autobiographical reminiscences will survive the long and solid works in which Renan condensed the learning of his time If so, it will be due more, one may think, to the charming picture he has left us of the Breton life and country and friends of his youth than to the account of the long drawn struggle which took him at last from his early faith and intended profession

Most people who have a sense for such things have read the "Souveneur de Jeunesse" long ago, but they would do well to renew their acquaintance in Mr Pitman's quite competent and readable translation, and with the aid of Dr Coulton's useful sign posts It must suffice here to note two passages of special interest to scientific readers, one of which is quoted by Dr Coulton in his introduction Renan, writing after these "Souvenirs" in 1891 just before his own death in 1892, uttered one of the most remarkable judgments on public affairs on record "My dear children of the new generation, how many things you will know forty or fifty years hence which I shall never know! How will the inmost soul of the Kaiser William II develop? What will be the end of the conflict of European nationalities? What turn will the social question take? What will be the coming fate of the Papacy?"

The other passage occurs towards the end of the "Souvenirs" themselves There was a moment before Renan left St Sulpice when he might have taken up the study of natural science, and he says that he much regrets that he did not do so "It is by chemistry at one end and by astronomy at the other, and especially by general physiology, that we really grasp the secret of existence of this world and of God, whichever it may be called" Possibly, if he had done so, mankind might have gained from a mind so industrious, synthetic, and humane, a view of scientific evolution as a historic whole which we have still to build He would scarcely have been a great discoverer, he might have been one of the greatest historians of science F S MARVIN

Steam and Gas Engineering a Text covering Power Generating Apparatus utilising Energy released by the Combustion of Fuels By Prof Thomas E Butterfield Pp xv + 481 (London Macmillan and Co, Ltd, 1929) 18s net

PROF BUTTERFIELD holds the chair of heat power engineering at Lehigh University, and his text book has been written to fill what he felt to be a real lack in material for teaching the subject He is therefore concerned more with elementary principles and general descriptions of plant than with the work of the designer and the operating engineer, and the student who wishes to master any branch of heat power engineering will have to supplement his reading by consulting the books and articles mentioned in the bibliographies appended to each chapter Most of the books referred to are either British or American

The book may be divided roughly into four sections, the first treating of fuels, combustion, boiler furnaces, grates, the boilers themselves and their auxiliaries, the second deals with the various types of reciprocating steam engines, the third with steam turbines, and the last with internal combustion engines Though owing to the extensive use of the motor car the aggregate horse power of internal combustion engines exceeds the total horse power of steam plant, yet the place occupied by the latter in central power stations gives it the greatest engineering interest, and more space is thus given to steam than to gas and oil

All the usual features found in steam plant are dealt with, including mechanical stokers and condensing plant, and there are chapters on heat and work, the properties of steam, the laws of gases, gas and steam cycles, and the nozzle and blade calculations for steam turbines, and the student thereby gets a broad foundation on which to base his further studies A few historical notes are given regarding gas and oil engines, and similar notes might well have been given on steam engines and steam turbines It is somewhat strange to read descriptions of steam turbines without meeting with the name of Parsons

Kristallzeichnen Von Dr Robert L Parker Pp vi + 112 + 50 Zeichenblattern (Berlin Gebruder Borntraeger, 1929) 20 gold marks

THIS is one of the few books which deal exclusively with the drawing of crystals It consists of a threefold division into text, tables, and drawing sheets The text forms a practical introduction to crystal drawing, and theory is well blended with practical application

The first few chapters are devoted to general questions such as the choice of a projection, and to the older methods of drawing as on the projection of the crystal axis, and with the aid of the stereographic and gnomonic projections The position of the projected axes is given by co ordinates (Weber's method), and a chapter is devoted to the method of determining the co ordinates for the orthographic and clinographic projections in the case of each crystal system Each method of drawing is illustrated with worked examples

In the second half of the book is explained the author's new "Bildkantenazimute" method This, without loss of accuracy or applicability, offers a great saving in time and labour over the older methods, and has the great advantage that it does away with confusing constructional lines The slope of the edges is given by an angle measured in azimuth from a fixed point The angles are derived by a simple calculation from the co-ordinates of the axial cross and the indices of the edges together with the axial ratio Once calculated, the values are then available for all subsequent drawings of the same species Prepared drawing sheets allow of rapid plotting of the edges

The method may be adapted to any projection, but in the tables are given the angular values for the orthographic and basal projection for twenty minerals in addition to all the cubic values It is the obvious method to use in drawing cubic crystals The text is well illustrated

The Journal of the Institute of Metals Vol 42 Edited by G Shaw Scott Pp xii + 846 + 48 plates (London The Institute of Metals, 1929) 31*s* 6*d* net

The original papers contained in this volume were presented at the meeting of the Institute in Dusseldorf last autumn, and include several contributions from Continental metallurgists They fall into three main groups The first includes a general discussion on metallographic methods, as well as separate papers on dilatometry Here will be found a useful survey of modern methods of investigation, including some of very recent development A second group is concerned with recent progress in melting and casting non ferrous metals, special attention being given to electric heating The extent to which electric heating has replaced the use of direct fuel in the German copper and brass industry is very striking, and the laboratory metallurgist, accustomed to the difficulties of vacuum operations, may be surprised to find that charges of as much as four tons of metal have been successfully cast *in vacuo*, an induction furnace being used for the purpose

The subjects of corrosion and chemical attack are represented by several papers, one of which deals interestingly with the formation of patina on copper, and another with the wastage of locomotive fire box stays The influence of the Non ferrous Metals Research Association in encouraging and supporting work of scientific as well as of practical interest is conspicuous The abstracts and bibliography occupy no less than 360 pages, and this section of the volume is, as usual, very thorough in character, and indispensable to the metallurgist

Applied Inorganic Analysis with Special Reference to the Analysis of Metals, Minerals, and Rocks By Dr W F Hillebrand and Dr G E F Lundell Pp xix + 929 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 42*s* 6*d* net

This important work is the result of prolonged experience on the part of both authors, whose publications on analytical subjects are well known Although attention is more especially directed to metal, mineral, and rock analysis, the book is really a general treatise on quantitative analysis, and as such will appeal to a wide circle of readers The treatment is essentially practical, and the details necessary for successful procedure are carefully described

References to the literature are given very fully, and a great number of critical observations and comparisons of methods add considerably to the value of the book The treatment is not exhaustive, and the reviewer has failed to find more than one method which he has himself used with success, but the authoritative treatment of the methods selected is entitled to the high praise which the book as a whole fully deserves Although the price is somewhat high, the saving of time which the possession of the book will realise makes it worth the cost Every chemical laboratory will find the book of great value

Anthropology of the Syrian Christians By Rao Bahadur L K Ananta Krishna Ayyar Pp xvii + 338 + 48 plates (Ernakulam Cochin Government Press, 1926)

The Syrian Christians of Malabar are, in their way, one of the most interesting communities in India Originally a single community, they afterwards divided themselves into various sects in circumstances over which they had no control, each with its divergent set of social customs and religious differences Yet all of them claim equally to be descended from, and themselves to be, true followers of the Apostle Thomas They have on many occasions attained prominence from their numerous and interminable disputes about the possession and administration of church property, a character, however, in which they are not peculiar either in India or elsewhere

Mr Krishna Ayyar's investigations into the manners and customs of the Syrian Christians of Malabar, Cochin, and Travancore were originally made so long ago as 1910, and the results embodied in vol 2 of "Cochin Tribes and Castes" Later opportunities for intensive study have enlarged the material, and the Cochin Government has now sanctioned its publication in a separate volume Four chapters are given to the history of the Syrian Church, and the remaining thirteen are devoted to the description of manners and customs It is interesting to note that not only are there many survivals of Hindu customs among these Christians, but also they show the same tendency to frequent fission into sects which is to be observed in the formation of castes and sub castes by division among the Hindus

The Statesman's Year Book Statistical and Historical Annual of the States of the World for the Year 1930 Edited by Dr M Epstein Sixty seventh Annual Publication Revised after Official Returns Pp xxxi + 1458 (London Macmillan and Co , Ltd , 1930) 20*s* net

The changes in the new issue of this familiar work of reference are in matters of detail The political world has been relatively quiet and there are few changes of frontiers or adjustments of territory to be recorded except the acquisition by Norway of a few polar islands Yugoslavia now appears under that official name in place of the old Serb, Croat, and Slovene State As usual, the revision of detail has been thorough, and an immense mass of useful statistical and descriptive matter appears within a small bulk The copious bibliographies of official reports and non official publications have been again revised There are two coloured maps, one showing Northern China with Manchuria and Mongolia, and the other Lithuania with the territory claimed by both that State and Poland The usual introductory tables give world output of various commodities

Complete Spectral Diagrams of Crystals

IN NATURE of Dec 21, 1929 (vol 124, p 946), W Linnik describes a complete spectral diagram [1] of quartz produced by a conical X ray pencil, which pencil is obtained by the movement in two directions of a narrow pencil about a point The rays reflected

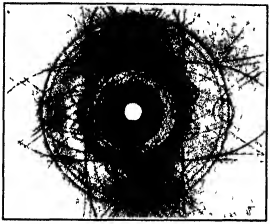

FIG 1

from inside the crystal come out on the side of the crystal opposite the source of rays and fall on a photographic plate A screen is moved with the ray and prevents the direct unreflected pencil from falling on the plate

This method permits the production only of a very

FIG 2

limited part of the complete spectral diagram Far more complete diagrams, as shown in Figs 1, 2, and 3 are obtained by reflection at the surface of a rock salt crystal backwards by using a very broad conical pencil Fig 6 of Seemann [2] shows the arrangement of apparatus to produce such diagrams, provided that the photographic plate is placed parallel to the surface of the crystal and not perpendicular

The chief difference from Linnik's diagrams consists in the presence of closed circles and ellipses The short hyperbolic segments of Linnik are only present in Fig 2 within the two circles In Fig 2 the focus was in the plane of the photographic plate—in Figs 1 and 3 it was not in this plane In addition to this, the

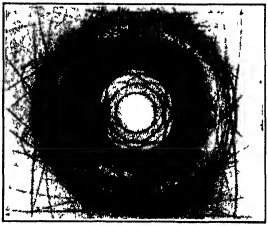

FIG 3

distances between the crystal and the point focus of the X ray tube and between the former and the photographic plate were different in the three diagrams A screen or diaphragm is not used in this method and all parts of the apparatus are kept fixed during the exposure

Adsorption from Solutions containing Two Solutes

ACCORDING to Gibbs's theory of capillarity, since the surface energy of a solution is at the minimum compatible with the other conditions of equilibrium, a substance which lowers the surface tension will be present at the interface in greater amount than in the bulk of the solution If two solutes are present, both of which lower the surface tension, it might be expected that that which causes the greatest surface tension lowering will be adsorbed to a relatively greater extent than the other If the difference is considerable, we may get the almost exclusive adsorption of the more active substance

We have determined, by means of the capillary electrometer, the surface tension lowerings produced at polarised mercury surfaces by solutions containing two surface active substances, and have found cases in which the lowering caused by the mixture is identical with that produced by the more active substance, when present alone For example, $M/20$ sodium *o* toluate by itself causes smaller surface tension lowerings than $M/20$ sodium cinnamate at all potential differences (Fig 1), and the electro capillary curve of the mixture is identical with that of $M/20$ sodium cinnamate When the sodium cinnamate concentration is reduced, while that of the toluate remains constant, the curve of the mixture remains identical with that of the cinnamate to below $M/50$ With $M/60$ sodium cinnamate, the effect of $M/20$ sodium toluate first becomes observable

The surface tension lowerings of $M/50$ sodium cinnamate and $M/20$ sodium toluate separately at $V = -0.3$ volt, are equivalent to 3.4 and 2.1 cm of mercury in our apparatus, so that a difference in the lowerings caused by the two substances of about 30 per cent is sufficient to prevent the adsorption of sufficient toluate to cause a measurable change of surface tension. We have obtained similar effects with seven mixtures of salts of organic acids.

Similar observations have been made with mixtures of two neutral substances. In many cases, owing to

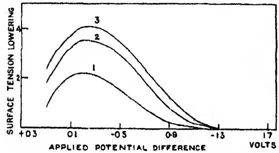

FIG. 1.—1. $M/20$ sodium o-toluate. 2. $M/50$ sodium cinnamate and $M/50$ sodium cinnamate + $M/20$ sodium o-toluate. 3. $M/20$ sodium cinnamate, and $M/20$ sodium cinnamate + $M/20$ sodium o-toluate.

the maximum surface tension lowerings occurring at different potentials, the curves of the two substances intersect and one substance causes the greater lowering on one side of the point of intersection, the other substance on the other side. In such cases we have found that the curve of the mixture approaches the higher curve on each side of the point of intersection (Fig. 2). Near the point of intersection the lowering is greater than that produced by either substance separately, but much less than the sum of the two. This type of behaviour is exhibited by the systems,

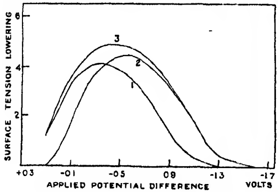

FIG. 2.—1. $M/20$ phenol. 2. $M/100$ caffein. 3. $M/20$ phenol + $M/100$ caffein.

caffeine phenol, phenol lactose, caffeine lactose, and salicin saccharose, all of which have been measured in $M/2$ sodium sulphate solution.

According to Langmuir's theory of adsorption as applied to the surfaces of solutions, the relation between the number of molecules of a solute adsorbed (Γ) and its concentration (c) in the solution is

$$c(1 - A\Gamma) = k\Gamma,$$

where A is the surface area occupied by each adsorbed molecule, and k a constant. It can be shown that this relation leads to Szyszkowski's equation, $\Delta\rho = \frac{RT}{A}\log\left(\frac{c}{a}+1\right)$, where $\Delta\rho$ is the surface tension lowering and $a = k/A$. Now $1 - A\Gamma$ is the fraction of the area of the interface which is unoccupied by any solute molecules, and if a similar relation applies when two solutes are present, the amounts adsorbed are determined by the equations

$$c_1(1 - A_1\Gamma_1 - A_2\Gamma_2) = k_1\Gamma_1,$$
$$c_2(1 - A\Gamma_1 - A_2\Gamma_2) = k_2\Gamma_2$$

It can be shown that these equations lead to the relation

$$\log_e \frac{(\Delta\rho_1)_{c_2}}{(\Delta\rho_1)_0} = -(\Delta\rho_2)_0 \quad \frac{A_2}{RT},$$

where $(\Delta\rho_1)_{c_2}$ is the lowering produced by the first substance in a solution containing the second substance at a concentration c_2, and $(\Delta\rho_1)_0$ and $(\Delta\rho_2)_0$ the lowerings produced by the two solutes separately at the concentrations at which they are present in the mixture. It has been found that this relation applies reasonably well to the data for neutral solutes, A_2 varying to a certain extent with the applied potential difference. In mixtures containing surface active ions, the effect of the less active substance is somewhat less than that predicted by the equation, probably owing to the electric field of the adsorbed ions hindering the adsorption of more ions of the same sign. A complete account of this work is to be published in the *Journal of Physical Chemistry*.

Synapsis and Chromosome Rings in *Œnothera*.

IN a letter in NATURE of May 17, p. 743, Dr. Darlington, having observed what he believes to be parasynapsis or side by side pairing of threads during meiosis in certain plants, mostly allied to the Liliaceæ, where such conditions have been described before, assumes that meiosis in all other organisms must fit in with his particular scheme of events. Since 1911[1] I have been inclined to the view that some organisms conform more nearly to the parasynaptic story, while others agree essentially with the telosynaptic account. Certainly nothing that Dr. Darlington has observed has given me any reason to alter that view.

Œnothera is by no means the only genus in which the observations lead naturally to a telosynaptic conclusion. In *Lathyrus*, Dr. Latter[2] has shown that the evidence of telosynapsis is very clear, and no fair treatment of her observations can twist them into a parasynaptic interpretation. The spireme is shown from a remarkably early stage in the heterotypic prophase to be a continuous single thread, which gradually shortens and thickens and becomes arranged in a characteristic way, with seven loops radiating from the centre. Each loop clearly represents a pair of chromosomes attached end to end. A parasynaptic interpretation is not only contrary to all her observations, but also would involve as well the disruption of the individuality of every chromosome at this period.

This is not the place to discuss cytological details, but Darlington has referred to the work of two of my pupils, and a word is necessary on this subject. Any one who reads the papers of Dr. Sheffield,[3] only one of which was referred to by Darlington, and examines her drawings, will recognise the very high quality of her technique, and the cogency of the evidence for telosynapsis in the forms she has studied. Her results need no defence from me. For example, in the segmented spireme stage the connexions between the chromosomes are sometimes short and sometimes very long, yet they are invariably single; but on Darling

ton's hypothesis they should be double, as he finds them to be in *Tradescantia* and other forms

Catcheside's very interesting case[4] of a triploid *Œnothera* with its 21 chromosomes all arranged end to end in the spireme to form a closed ring is, if correct, a fatal blow to Darlington's theories as applied to *Œnothera*, as he has admitted Having admitted so much, he now denies the facts, but Mr Catcheside's preparations have been examined by other cytologists besides myself, and we were agreed that his interpretation is correct, although the evidence is not, perhaps, so copious as one would like Moreover, the usual distribution of the chromosomes as 10 + 11 in the reduction division, which I first showed in 1909[5] and Catcheside has recently confirmed is the result which would be expected from a ring of 21 linked chromosomes with successive members oriented towards opposite poles The early conclusion of mine[5] which Darlington quotes, "that there is usually no meta phase, strictly speaking", in *Œnothera*, has been abundantly confirmed by the work of many subsequent investigators, the zigzag arrangement of the chromosomes at this time being in marked contrast to their usual alinement

Cleland (who has also described telosynapsis in many *Œnothera* forms) and Blakeslee[6] have recently shown that the rings of chromosomes in many *Œnothera* species have a possible explanation on the basis of segmental interchange according to Blakeslee and Belling's hypothesis for *Datura* While such comparisons are to be welcomed as representing a possible advance, there are, nevertheless, important differences between the two genera, and in any case in recent years there has been evidence to suggest (in such papers as that of Latter on *Lathyrus*) that segmental interchange can also take place in connexion with telosynapsis and not merely as the result of lateral pairing of threads Blakeslee and Belling's hypothesis of segmental interchange is therefore quite independent of parasynapsis, and there is no reason why its occurrence in *Œnothera* should be regarded as an indication of lateral pairing

Whether my work on *Œnothera* during the last twenty years and more has been "sterile" can safely be left to others to judge Those who wish to form an unbiased opinion should read Lehmann's "Die Theorien der Œnotheraforschung" (Fischer, 1922), which deals with the whole subject up to 1922 They will then be able to realise the important part which the cytological investigations of *Œnothera* have played in the history of genetics A more recent monograph (Gates, 1928[7]) deals also with some of the later work My first critical paper on the subject[8] showed a telosynaptic course of events, contrary to my anticipations at that time, and of the scores of papers on the subject published since, every critical one has repeated the same story in all essentials, though with varying details and additional facts Especially has the constancy of chromosome linkages been brought out in recent years Various parasynaptists have endeavoured to make the facts fit into their ideas, but without conspicuous success Notably the Gregoire school have investigated *Œnothera*,[9] but failed completely to find evidence of parasynapsis They could only repeat in its essentials the telosynaptic account Recently Weier[10] has made another attempt But anyone who examines his figures, for example, Figs 18 22 and 36 39, will see that the special method of fixation which he recommends has been anything but a success, with the result that the chromatin has flowed together to form what he calls the "central coagulum", which is obviously not a natural condition

The idea that all organisms must conform to one scheme of pairing has seriously retarded progress in this field There are signs that some of the younger cytologists are developing less stereotyped ideas on this subject

Interpretation of Infra-Red Frequencies of the Diamond

NATURE of May 10 contains two interesting communications one by Robertson and Fox and another by Ramaswamy—on the infra red frequencies of the diamond as determined directly and as inferred from the Raman effect With the view of interpreting these lines, it appears to me to be of interest that attention be directed to the following facts

Some time ago (*Sitzungsberichte der Preuss Akad der Wiss*, **33**, 447, 1926), from an analysis of the change of the specific heat with temperature, I had concluded that the atoms of a number of crystallised substances are capable of assuming two states differing in energy to so small an extent that the higher quantum state is excited thermally at comparatively low temperatures The diamond is one of these substances Formerly, the attempt was made to interpret its specific heat with the help of a Debye function of $\theta = 1860$, but now a much better agreement with the experimental results is found by means of a Debye function of $\theta = 2340$ and the supposition that the C atoms can assume two states differing in energy by 2120 calories per mol

If we therefore desire to compare the infra red lines with the thermal data, we must consider not only the altered frequency but also the possibility that the higher quantum state can be excited by light From the above mentioned energy difference a wave length of 13 4 μ can be calculated (experimental error about 10 per cent) Reinkober has, in fact, found an absorption band at 14 μ Now Ramaswamy believes he has discovered a diffuse band which can be calculated to correspond to a wave length of about 15 16 μ Taking the experimental error into account, which may be considerable in these Raman measurements, it is quite possible that this diffuse band is due to the transition to the higher quantum state brought about by the action of light Whether this is actually the case could be determined first by a more accurate determination and discussion of the infra red bands, and in the second place by determining the variation of the intensity of the lines with temperature, for which a perfectly definite course would be prescribed by the above mentioned interpretation

I may mention that the existence of an X ray reflection from the 222 plane of the diamond may be connected with these two energy states of the C atom, and moreover that, in the case of silicon and grey tin, both having the same crystal structure as the diamond, the specific heats point very definitely to the same phenomenon

Scattering of X-Rays by Bound Electrons

THOUGH Bergen Davis and his collaborators (*Phys Rev*, 23) have reported the detection by means of an ionisation chamber of the modified lines (over and above the Compton effect) produced by the scattering of a monochromatic beam of X rays by carbon in a direction at right angles to the direction of propagation, Coster (NATURE, Aug 10, 1929), Ehrenberg (*Zeit f Phys*, 53), and Kast (*Zeit f Phys*, 58) have failed to observe the same on the photographic plate In a previous note to NATURE, it has been pointed out by me that a portion of copper $K\alpha$ radiation in passing through carbon decreases its frequency by an amount equal to that of the $K\alpha$ radiation of carbon The accompanying photograph (Fig 1) shows the effect of copper $K\alpha$ radiation in passing through carbon, nitrogen, and oxygen The known lines are marked as usual, while the new ones are shown by numbers The white mark on the copper $K\alpha$ line is due to the fact that a piece of aluminium was placed just in front of the photographic plate to decrease the blackness of the plate in this region

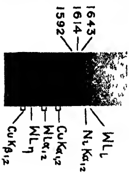

FIG 1

The lines are diffuse and very broad, and as such they could only be measured with a glass scale Longer exposure does not improve the relative intensity of these lines, as the general radiation tends to blacken the whole plate The three lines 1592 X U, 1614 X U, and 1643 X U are interpreted as due to the scattering of copper $K\alpha$ radiation by carbon, nitrogen, and oxygen The frequency differences (ν/R) between the copper $K\alpha$ radiation and these lines are 20 1, 27 6, and 37 7 respectively, whereas the frequencies (ν/R) of the $K\alpha$ radiations of carbon nitrogen, and oxygen are 20 4, 28 7, and 38 3 respectively

Similarly, a portion of the nickel $K\alpha$ radiation in passing through carbon and nitrogen shows new lines the wave lengths of which are 1719 X U and 1746 X U, and the frequency differences between the nickel $K\alpha$ radiation and these lines are 20 0 and 28 1 respectively

The absence of any modified lines by scattering (Coster, Ehrenberg, and Kast) in any other direction than that of propagation suggests that in all probability *in an interaction between a quantum and a bound electron*, the former on its passage through the medium loses a part of its energy and an equivalent amount of momentum in raising the electron from one orbit to the other, and is propagated in the original direction as a modified wave of lower frequency

Fluorescence of Mercury Vapour in the Far Ultra-Violet

SOME years ago one of us (Terenin *Zeits f Physik*, 31, p 40, 1925) observed a strong re emission of the aluminium line at 1854 A in the fluorescent spectrum of dense mercury vapour excited by an aluminium spark A great deal of work has been done since on mercury band fluorescence, but this re emission has not been recorded again This can be explained by the strong absorption of the radiation in ordinary spectrographs with thick quartz and a long light path in air, a very small home made fluorite spectrograph was used in the experiment mentioned Last year this subject was re examined by us in more detail The part played by absorption was shown clearly by the fact that an exposure of five hours was needed to record the emission with an ordinary small quartz spectrograph, whereas five minutes sufficed with the fluorite one In spite of the short focal length of the lenses (5 cm) the dispersion of the fluorite prism was sufficient to show the aluminium lines at 1854 A and 1862 A clearly resolved

Re emission of the 1854 A line begins to be noticeable at a much smaller vapour density than is required for mercury band fluorescence in the nearer ultra violet and the visible At a vapour pressure of about 10 mm, the re emission is quite conspicuous On raising the pressure of the vapour, the aluminium lines at 1862 A, 1935 A, and 1990 A appear in succession, following the development of the well known continuous absorption band to the long wave length side of 1850 A There is in addition in the fluorescent spectrum a continuous background, which spreads with increase in vapour density from 1854 A to 2345 A, where it ceases abruptly A similar emission, likewise localised in the neighbourhood of the resonance line $1^1S_0 - 2^1P_1$ of the atom, has been observed in the case of cadmium by Kapuscinski (*Zeits f Physik*, 41, p 214, 1927) The remarkable re emission of exciting lines is no doubt of molecular origin, but its exact mechanism is still not clear

On heating the vapour to 800° C at constant pressure, the spectrum described above is quenched as a whole, which suggests a common origin for the re emitted lines and the continuous background

The presence of small traces of gases does not have the strong quenching effect which occurs with the near ultra violet and visible fluorescence This is consistent with the view that the state to which the molecule Hg_2 is raised by the absorption of the aluminium lines has a much shorter life than those responsible for the fluorescence in the near ultra-violet and visible, the duration of the latter has been shown to be of the order of 10^{-3} sec (Rayleigh, *Proc Roy Soc*, 114, 620, 1927 Pringsheim and Terenin, *Zeits f Physik*, 47, p 330, 1928) It is of interest that the band at 2345 A (probably corresponding to the 2^3P_2 state of mercury) is strongly quenched by traces of gases, and so does not seem to be connected with the far ultra violet fluorescence studied here

A quantitative investigation of the subject is in progress

The Acquired Characters of *Alytes*

IN NATURE of April 12, p 562, Dr Charles Walker draws a parallel between the well known experiments on plants transferred to other climate or soil and Kammerer's endeavours to prove the inheritance of acquired characteristics, especially in *Alytes obstetricans* Without again entering into the whole matter, I would only like to point out that Kammerer (*Roux' Archiv*, 45, 324, 1919) states distinctly that the *Alytes* returned to their habitual temperature retained the *habit* acquired at the high temperature artificially employed of copulating in the water (p 328), and that the fourth generation of *Alytes* which were returned to normal conditions developed the nuptial pad in a male of the F_4 generation It is the *habit* which was

induced and retained after return to normal climate The deprivation of water proposed by Walker would not have been equivalent to a return to former conditions, but induction in the opposite direction Furthermore, Kammerer himself did not think the nuptial pad of *Alytes* an example of a newly acquired characteristic, but suggested that the character had been inherited from the frog ancestors, which normally have these pads (p 326) In his English account entitled "The Inheritance of Acquired Characteristics" (New York, Boni and Liveright, 1924), Kammerer writes (p 6) on the pads of *Alytes* 'admittedly an atavism and not a new acquisition" He would not have opposed Walker's statement that *Alytes* had both potencies either to develop or not to develop the nuptial pad, one or the other turning up under certain external conditions Valentin Haecker has termed this 'pluripotency" ("Pluripotenzerscheinungen, synthetische Beiträge zur Vererbungs und Abstammungslehre Jena, Fischer, 1925)

Lastly, I must mention the great difference of method in the old experiments on plants and Kammerer's experiments on the transmission of acquired characteristics in those other cases, in which not only a habit, but also a morphological or colour character was immediately affected Whereas the plants were put back under the former conditions, Kammerer placed the progenies of animals modified by diverging external factors into an intermediate surrounding, thus avoiding the instantaneous counteraction of one modification by the opposite one The difference of these progenies in the same surroundings was taken as proof of the transmission of the induced modifications Returning to the case of *Alytes*, we have in the same surroundings the progeny of parents which have always been kept at normal low temperatures and breeding on land, and the progeny of those exposed for several generations to high temperature in water As in Kammerer's other experiments on the transmission of modifications, we have *different* characters in the *same* surroundings whereas in the experiments on plants referred to by Dr Walker, there were *different* characters in *different* surroundings, and only a small divergence in time of growth marked the origin of two lots side by side in the old conditions A comparison of the two lines of experiment can, I think, only be made in so far that both have furnished cases of 'pluripotency' HANS PRZIBRAM

Evolution of the Hive-bee

IT has been recently suggested, or maintained, that the case of the worker bee can be explained on the principles of genetics and mutation, but not on the Lamarckian hypothesis The queen bee or fully developed female shows no maternal or industrial instincts, but she transmits such instincts to her daughters, the worker bees, which are sexually undeveloped females

The question then is whether the absence of the above instincts in the queen bee is due to mutation, or to disuse It can scarcely be disputed that the hive bee is descended from a form like the humble bee or wasp in which a solitary fertilised female begins the summer by laying eggs, collecting food, making cells, and nursing the larvæ, and ends by resigning all these tasks to her sexually imperfect daughters The fact that the worker bee possesses and exhibits the industrial and maternal instincts is proof that it has inherited the genes of these instincts from its mother, the queen bee But if the absence of the same instincts in the queen bee was due to mutation, she must have lost the genes of those instincts, and the worker bee could not inherit them Even if we suppose that the mutation was only a modification of the genes which prevented them becoming active, this modification would be passed on by heredity to the worker

On the other hand, on the hypothesis that the loss of the instincts in the queen bee is due to many generations of disuse it is easy to explain their presence and activity in the worker For the suppression of the instincts will be impressed on the genes in association with the hormones present when it took place, namely, the hormones of the fully developed female reproductive organs The workers will inherit the genes with the same modification, and as in them the reproductive system is never fully developed or active, the modification will never show itself, and the instincts will be in full activity

The difference between the queen and the worker bee is thus of the same kind as that between a male with secondary sexual characters and a female in which they are suppressed by the absence of the testis hormone, and I have not yet heard any explanation of the origin of the influence of sexual hormones on the development of secondary sexual characters on the theory of mutations J T CUNNINGHAM

Chiswick, April 29

Science and Philosophy A Proposed International Conference

THAT great and epoch making work of Eddington, "The Nature of the Physical World," must have raised afresh in many minds the ever recurring question of the nature and meaning of science and its relation to philosophy and to our ordinary concepts of the familiar world Many eminent men of science and philosophy have dealt with this age long question in relatively recent times One might, for example, cite Comte, Clifford, Huxley, Spencer, Balfour, Stallo, Mach, Ostwald, Pearson, Poincaré, Alexander, and Bergson The rapidly advancing tide of scientific research during the last twenty five years has made the question still more urgent, although it has been frequently discussed and illuminated by many acute minds of the highest quality To mention again only a few examples, the names of Russell, Whitehead, Eddington, Jeans, Perrin, Rignano, Smuts, Einstein, Minkowski, Weyl, Heisenberg, de Sitter, Henderson, Morgan, Campbell, Lewis, Bridgman, and Ritter will occur to everyone

My proposal is that poets, philosophers, psychologists, biologists, mathematicians physicists, and chemists should be brought together to discuss this matter and, if possible, to elucidate it There is urgent need to bring such men together and to do something towards a synthesis of thought and the advancement of a true *philosophie scientifique* Perhaps the meeting of the British Association in 1931 might offer a possible occasion Another possibility would be a meeting in Italy in celebration of the memory of Prof Eugenio Rignano, who by his own writings and his editorship of *Scientia* did so much in the cause of scientific synthesis

The ideal would perhaps be a special international meeting held, say, every five years I believe very firmly that if the intellectual leaders of the world could meet at regular intervals and explain to each other, to their immediate audience, and to the world at large, their doubts and hopes concerning what the human mind has created from the data of sense the cause of civilisation would be materially aided

Do Cockroaches eat Bed Bugs?

Howlett, writing on bed bugs in Lefroy's book on "Indian Insect Life", states "In America cockroaches and small red ants are mentioned by Marlatt (*U S Ent Circular*, No 47) as being fond of eating bugs, the ants in particular being effective checks" In the account of cockroaches, however, Lefroy himself writes, "these insects are 'scavengers', and *none is known to feed on living plant tissue or to attack living insects*" In view of the contradictory nature of the two statements, my experience with these insects at Bombay is perhaps worth recording

(1) It was observed that cockroaches generally frequented bug infested bedsteads at night, although they were sometimes seen under the mattresses in the daytime also

(2) The presence of cockroaches in very large numbers on a bug infested cot was once noted to be associated with the complete disappearance of bugs, in a fortnight, after the cot was discarded from use

In order to exclude alternative explanations for the presence of cockroaches and disappearance of bed bugs in the second case, direct experimental evidence was sought to discover if the cockroaches were really capable of eating bed bugs Cockroaches were kept singly with one or more living bed bugs, in glass jars, each guarded at the mouth by a fine piece of muslin, tightly tied by means of a string It was found that at least *Periplaneta americana* ate bed bugs, but preferably those young ones which had soft blood gorged abdomens Adult bugs with comparatively harder exoskeleton were sometimes rejected The maximum number of bed bugs eaten by a cockroach was three out of twelve supplied to it in forty eight hours, after which, during the following twenty four hours, the cockroach preferred to starve The repetition of the above experiments confirmed Marlatt's observation that cockroaches of this species will eat bed bugs

Band Spectrum of Sulphur

The absorption spectrum of S_2 vapour has been investigated by Henri and his pupils (Nature, **114**, 894, 1924, *C R*, **179**, 1156, 1924, *Jour de phys*, **8**, 289 1927) and by Rosen (*Zeit f Phys*, **43**, 69, 1927, **48**, 545, 1928) They found a band system leading from the vibrational levels of the normal electronic state of the molecule to the vibrational levels of an excited electronic state They also found that those bands for which the upper states lie above a certain energy value are diffuse, a fact which can be explained if one assumes that in these states the molecule has the possibility of dissociating spontaneously into separate atoms, a phenomenon called predissociation by Henri (see, for example, Kronig, *Zeit f Phys*, **50**, 347, 1928)

At the suggestion of Dr Kronig, I investigated the spectra obtained by passing a high voltage discharge through hydrogen sulphide at a pressure of a few millimetres It showed that the same band system obtained by the observers mentioned above in absorption appeared here in emission, with the one difference that the bands which in their investigations were diffuse are here entirely absent After the current had been passed through the discharge tube for some time, a deposit of sulphur appeared on the walls

These facts can be understood if it be remembered that the S_2 molecules produced by the discharge and raised to the levels in question have a very short lifetime They will hence dissociate before they have a chance to fall back to the normal state under emission of radiation, so that the emission bands starting from them are very faint or entirely absent

Besides the band system just discussed, the photographic plates showed another band system with its maximum intensity in the region of 2570 A To judge from its appearance, it is also due to S_2 It is hoped to investigate in greater detail the structure of these bands, particularly with regard to a possible intensity alternation

Water-meadows and River-flow

I am glad to see from Dr Vaughan Cornish's review on pp 737 8 of Nature for May 17 that the Council for the Preservation of Rural England is directing attention to the unsuitability of water meadows for dwellings and to the fact that they serve as safety overflows for inhabited districts lower down the river in times of heavy flooding The æsthetic advantage of these flats is also accentuated

A point which does not seem to have been made is that water meadows are essential for the existence of the river itself If recent proposals for measures to ensure the rapid passage seaward of winter rainfall are adopted the summer flow of such rivers as the Thames is likely to become negligible In winter as much as 10 000 million gallons may pass over Teddington Weir in twenty four hours, in summer as little as 100 million gallons If the water now stored in the land around the upper reaches during winter floods is not allowed to collect in the future, then it is difficult to see how the summer flow can be maintained even at its present level or how flooding near London can be prevented in winter The question affects navigation, sewage treatment, and water supply not only in the Thames but also in all such rivers Lord Desborough has directed attention to the doubtful future of the water supply of many districts

Flint Implements of Lower Palæolithic Age from the Mammaliferous Gravels of Yorkshire

On Feb 15 last there appeared in Nature the announcement of my discovery in Yorkshire of Upper Palæolithic implements, *in situ*, at the base of a glacial deposit of Pleistocene age

Messrs Dewey and Bromehead, of H M Geological Survey, have just completed an official examination of the sites under consideration, and, from the sections north of Bridlington, they have removed, with their own hands, numerous implements from the base of what they, also, consider to be a deposit of late Pleistocene age A detailed report of these investigations will be issued in due course

On Saturday, May 17, whilst examining, in their company, the mammaliferous gravels at Burstwick, in Holderness, I recovered therefrom a Levallois-flake, which, from its stratigraphical position, cannot be later in date than the Early Mousterian period Last year, I found in this same deposit a small hand axe, flaked on one face only, both these specimens will be described and figured at a later date

The Metallography of some Ancient Egyptian Implements *

By SIR HAROLD CARPENTER, F R S, and DR J M ROBERTSON

IRON in ancient Egypt has been the subject of many publications, and, concerning such aspects as the approximate date of the beginning of the Iron Age, the use of meteoritic iron, and the source of the Egyptians' knowledge of iron making, many different opinions have been expressed With regard to some of these questions the position is such that evidence may be adduced in support of a variety of views each of which is at variance with certain portions of the total available evidence Concerning the approximate date of the beginning of the Iron Age there are, for example, two main categories of evidence, the direct and the indirect, and generally speaking, the conclusion arrived at depends on which type is regarded as the more reliable The evidence provided by the discoveries of iron articles, iron smelting furnaces, or references to iron in writings or paintings constitutes the direct evidence, whereas the existence of hard stone carvings which would appear to have required the use of iron tools in their execution constitutes the indirect evidence

Only six iron specimens which can be definitely shown to belong to the period 1300 B C have been found, whereas iron articles belonging to later periods are fairly plentiful On the basis of this evidence, Petrie has suggested that iron did not come into general use in Egypt until 1300–1200 B C, although it was apparently used sporadically for a period of from 2000 to 3000 years before this

A further indication of the late beginning of the use of iron is provided by the evidence quoted by Rickard,[1] that mural pictures surviving from the period prior to 2000 B C show weapons coloured yellow or red, representing copper or bronze, but none of iron, which was usually coloured blue in paintings subsequent to 1500 B C In the long lists of tribute collected in the days of the Eighteenth Dynasty (1580–1350 B C) iron is not mentioned, and Rameses II (1292–1225 B C) wrote to the King of the Hittites asking for a dagger In the innermost sarcophagus of Tut ankh amen, who died about 1360 B C, three iron articles were found—a dagger blade, part of an amuletic bracelet, and a miniature head rest Rickard infers from the position of these articles, which lay on the wrappings of the mummy, that they were the most precious things belonging to the dead Pharaoh, and that the iron was more rare and highly prized than the gold of which the sarcophagus was made Among the funerary chattels found in the annexe of Tut ankh amen's tomb were some miniature iron implements, and Howard Carter[2] suggests that these might have been "gifts to the young King to record the arrival or discovery of iron in Egypt"

All the foregoing evidence goes to show that iron, although not unknown in Egypt before 1200 B C, was very rare, and was probably not manufactured in that country The majority of archæologists accept this evidence as conclusive

If no appreciable quantity of iron existed in Egypt before 1200 B C, copper and bronze tools must have been the only ones available, and yet from the Fourth Dynasty (2900 B C) the Egyptians were accustomed to sculpture hard stones, such as granite and diorite According to Garland and Bannister,[3] "Many of the antique Egyptian statues are perfect examples of the sculpture's art, the hardest stones were carved and shaped with unfailing accuracy, faultless symmetry and definition sharp corners with perfect angles and knife like edges, gracefully curved and plumb straight lines, grooves and serrations deep and shallow depressions and reliefs, with delicate, undulating contours, or rigidly plane surfaces"

Sculpture work of this kind is known to have been done for a thousand years before the introduction of bronze, when copper tools only were available—but even with bronze tools it is difficult to understand how this work was accomplished The hypothesis that the Egyptians possessed some secret method of hardening copper has now been discarded, and two alternative explanations of their method of carving hard stone remain One, due to Petrie, is that the work was done by means of emery fed copper or bronze tools, the other, that steel tools were used Hadfield[4] goes so far as to suggest that "the ancient Egyptians were not only able to make steel for tools of all kinds, but also to cement and harden it, or, if not themselves steel workers, they obtained the necessary material and help from the workmen of another nation"

The existence of the hard stone carvings is difficult to reconcile with the evidence of the specimens found by excavators The scarcity of iron relics of the period prior to 1200 B C may perhaps be explained by corrosion, by the existence of a superstitious objection to the inclusion of iron among funerary objects, or by arguing that the total number of metal specimens found is at best only a small proportion of those that must have been used These arguments may, however, be met by appealing to the permanency of iron rust, and to the fact that many iron objects belonging to the period subsequent to 1200 B C have been found in tombs and elsewhere

We incline to the view that iron was rare in Egypt until about 1300 B C, for the evidence of this scarcity implied in the request of Rameses II to the King of the Hittites, and in the nature and position of the iron objects buried with Tut ankh amen, is certainly strong

The existence of a number of iron specimens definitely known to belong to the period 2900–1450 B C shows, however, that the Egyptians were acquainted with this metal for about fifteen hundred years before its use became general During this, what may be termed, sporadic Iron Age, it was

* Based upon a paper read on May 1 at the annual meeting of the Iron and Steel Institute

obtained in limited quantities either by home manufacture or by trade, and it has been argued that an intelligent people like the Egyptians would not have been content with a limited supply of this valuable commodity, but would have applied themselves to extending its production and manufacture The validity of this argument rests, however, on the assumption that the iron was found to be superior, at any rate in certain respects, to copper and bronze, in the working of which the Egyptians had already acquired remarkable skill On consideration it is quite clear, however, that the first efforts at iron making would be most unlikely to produce a metal which would commend itself to the Egyptians or any other ancient people previously acquainted with the use of bronze

We are liable to forget that the position of iron in modern civilisation is due to the abundance of its ores, the scale on which it can be manufactured, and the variety of alloys it forms with carbon None of these considerations would influence its position when it first appeared in Egypt The spongy mass of iron and slag obtained from the direct furnace required much heating and hammering to get rid of the slag and produce a coherent metallic lump From this material the desired articles would have to be laboriously cut and forged with frequent reheatings, and the final product—if free from carbon, as most direct iron was—would be softer than bronze, devoid of ornamental attributes, and liable to rust The manufacture of iron articles was therefore much more troublesome than that of similar articles in bronze, and when finished, the product would not display any properties superior to those of this alloy It is probable, therefore, that iron when first discovered was developed with most avidity among people not previously acquainted with other metals or not highly skilled in their use In Egypt conditions were far otherwise, and iron would probably be regarded as a curiosity, or something with possibilities, but not as an alternative to, or an improvement on, existing metals

The position of iron in ancient Egypt clearly did not depend entirely on acquaintance with the metal, the ores from which it could be extracted, and the means by which this could be accomplished Numerous other considerations have to be taken into account, and these may be summarised by stating that direct iron when compared with bronze did not possess sufficient advantages to compensate for the greater difficulty experienced in manufacturing useful articles

The usefulness of iron for tools, weapons, and implements of all kinds would be greatly enhanced when means were discovered for converting it into *steel* by the introduction of carbon and a further extension of the utility of this metal would follow the discovery of quenching With the development of these processes of carburising and quenching, iron, because of the *increased* hardness that could then be conferred on it, would assume a new significance, and it was probably from this time that it began to be taken seriously and the sporadic gave place to the real Iron Age

Although there is in existence a large collection of ancient specimens of iron, comparatively few of them have been examined by metallurgical methods, and this is largely due to the reluctance of archæologists to submit specimens for examination when they anticipate that this will involve their partial destruction It is certainly true that examination by chemical methods requires drillings to be taken, but microscopic examination can be carried out simply by polishing a part of the surface, and by this method a considerable amount of information can be obtained from the examination of ancient metal specimens without injuring them

FIG 1 —Specimen No 6, a chisel

Through the kindness of Sir Flinders Petrie, we have been able to examine nine representative specimens selected with his assistance from his Egyptian Collection at University College, London The specimens examined were as follows —

No 1 A portion of a sickle This specimen had been very badly corroded, and consisted mainly of iron oxide held together by a thin sheet of metal The sickle consisted of two parts, a back and a blade Sir Flinders Petrie considers that this specimen belonged to the Roman period, and was probably made in the second or third century A D

No 2 A small knife in good condition It is considered that this belonged to an early period in the Iron Age, and was probably made about 1200 B C

No 3 A knife with a bronze handle This specimen was in fairly good condition, although it showed marked surface corrosion and pitting It is regarded as belonging to the period about 1200 B C

No 4 A small knife in good condition It is not an Egyptian shape, and is believed to have been imported from Europe about 300 B C

No 5 This specimen is a very primitive piece of work, and it is difficult to say what it is Sir Flinders Petrie was unable to assign it to any period

No 6 A chisel in good condition (Fig 1) It is supposed to date from about 700 B C

No 7 A hoe in good condition This specimen is supposed to date from about 800 B C

No 8 An axe head, corroded It is believed to date from about 900 B C

No 9 An axe head in very good condition (Fig 2) This specimen is believed to belong to the same period as No 8, namely, about 900 B C

The examination of these specimens was carried out in such a way that practically no damage was done to them In each specimen a representative

area was polished and examined microscopically, micrographs being taken of typical structures The hardness of these typical structures was then determined by means of a Brinell hardness tester with a 1 mm diameter ball In all the specimens extensive variations in microstructure were observed Some of these were clearly the result of carburising and heat treatment, but others were due to variations in the composition of the original metal, which when produced in primitive smelting furnaces consists of particles that have been welded and not melted together

FIG 2—Specimen No 9 an axe head

The principal results that were obtained from examination of the specimens were, briefly, as follow —

No 1 This sickle consisted of two portions, a back and a blade Microscopic examination showed that the back consisted mainly of ferrite with a little carbide, indicating that it had been made from iron containing a very small proportion of carbon The blade, however, had been carburised so as to bring the carbon content up to about 0 35 per cent It had then been quenched in water and tempered at about 600° C (Fig 3)

No 2 This specimen, presumably made in the first place from almost pure iron, had been carburised so that the carbon content was raised to about 0 7 per cent at the edge From the edge towards the back the carbon content decreased progressively, and the microstructure and hardness varied accordingly After carburising, this knife had been heated to about 750° C and air cooled—thus producing a hardness of 269 Brinell at the edge

No 3 This specimen had been given a similar treatment to No 2, and the variations in microstructure were almost identical

No 4 This specimen had not been carburised or subjected to any other special heat treatment It was a double edged knife or dagger, and, whereas the middle of the blade was small grained and contained a fair amount of carbon, the edges were large grained and consisted of soft ferrite The hardness of the middle of the knife varied between 137 and 143 Brinell, that of the edges varied between 95 and 107 Brinell

No 5 This specimen contained a small amount of carbon and had been water quenched, thus producing a hardness which varied between 160 and 197 Brinell

No 6 This chisel had been carburised so as to produce a carbon gradient which varied from about 0 6 to 0 8 per cent at the edge to about 0 15 per cent $1\frac{1}{4}$ in from the edge It had then been heated at the edge and quenched by immersing the edge only

No 7 This hoe had been forged from direct iron and had received no further treatment

No 8 This axe head was badly corroded It had been carburised, but the treatment had not produced the highest carbon content at the edge It had then been quenched, but the original hard edge had evidently been removed by sharpening The highest hardness number obtained was 229 Brinell in an area of high carbon at some distance from the edge, the hardness at the edge was 207 Brinell

No 9 This axe head appeared never to have been used and was still protected by a blue film of oxide formed during the last heat treatment For this reason it had not been corroded and the edge was sharp and regular The carburising treatment had produced a carbon content of about 0 9 per cent at the edge, decreasing to a very small amount at 1 in from the edge Quenching the edge had resulted in the production of a hardness of 444 Brinell at the edge and a progressive decrease in hardness to 62 Brinell at 1 in from the edge

It is evident from the examination of these nine specimens that although the Egyptian process of extracting iron from its ores was very primitive and resulted in the production of almost pure iron containing some slag, yet the metal workers of the period were able to produce in small articles a great variety of properties by means of carburising and heat treatment All the articles examined do not show the same degree of skill in their manufacture

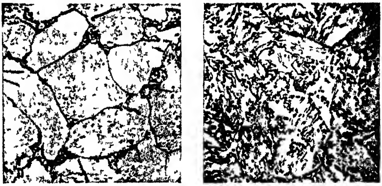

FIG 3—Specimen No 1, (a) back, (b) blade ×820

and heat treatment, even when they are considered according to their age But even at the present time there are notable differences in the extent to which the metallurgical knowledge and skill of the community is exhibited by different products, and the same would certainly hold in ancient Egypt when the facilities for the spread of knowledge were, by comparison, very meagre

So far as we know, the facts disclosed by the present work constitute the first definite evidence that carburising, quenching, and the advantages of heat treatment generally, were known and understood many centuries before the Christian era Hitherto, the earliest direct evidence of hardening has been that provided by Hanemann,[5] who observed a hardened structure at the edge of a specimen found during the excavations on the site of Steinsburg at Romhild in Thuringen This specimen belonged to a period about the beginning of the Christian era Indirect evidence of quenching at a much earlier date is provided by a reference in Homer

As already stated, the introduction of carburising and quenching would entirely alter the position of iron in comparison with bronze, and in our opinion it is probable that the Iron Age in Egypt did not properly begin until these processes were understood In other words, it was not until iron had been converted into steel that the Egyptians obtained a range of alloys which were superior in properties to bronze and capable of more varied applications In countries, however, where bronze was practically unknown, where notable skill in its manipulation had not been attained, or where the requisite ores were not readily available, the extensive manufacture of iron would follow more closely on its first discovery

There is no reason to suppose that the specimens examined in the present work represent the earliest specimens to be carburised and quenched The investigation has shown, however, that these processes were in use in the period 1200–800 B C As it was about this time that iron came into common use in Egypt, the information now obtained provides a substantial argument in support of the view that the discovery of carburising and quenching was the cause of the extensive utilisation of iron

Chinese and Malayan Medicine

IN his presidential address to the Chemical Section of the British Association last year, Prof G Barger pointed out that "the use of vegetable drugs led pharmacists to examine the constituents of plants and thus the foundations of descriptive biochemistry were laid" He suggested later on that 'whilst organic chemists are often eager to investigate the constitution of animal and vegetable substances, they are less ready to undertake the preliminaries of purification and isolation and are therefore less apt to discover new ones"

So far as Germany and Great Britain are concerned, it is probably true that less work is being done on the isolation of the proximate constituents of plants and that in France the additions to such knowledge are of a strictly limited character On the other hand, there is a distinct growth of such work in India, China, and Japan, and there are signs of a revival of interest in it in the United States The earlier British and German investigations of this kind were usually devoted to severely practical ends, such as the isolation of active principles from vegetable drugs or the preparation of colouring matters from natural dyestuffs, and it is just possible that the decline of interest is largely due to failure in supplies of new raw material worth examination Directors of laboratories associated with the application of chemistry to medicine are apt to be afflicted by enthusiastic and credulous collectors of native drugs, who bring home an ounce or two of mouldy roots and a romantic story of marvellous cures of diabetes, tuberculosis, or cancer, and expect the chemist to examine the one and believe the other

Much valuable work has been wasted in examining material of this kind Though there is still much to be done, we already have much information linking up the groups of the systematic botanist with particular types of chemical compounds, and there are already clear indications that in the future, work on the constituents of plants is likely to proceed on systematic lines to be settled by cooperation between the botanist and the chemist In this connexion it is satisfactory to find Dr Hooper employing his well earned leisure in identifying and recording the botanical sources of the drugs to be found in Chinese pharmacies in Malaya[1] The particular specimens identified were collected by Mr I H Burkill when Director of Gardens, Straits Settlements The number of specimens dealt with is 456, and they are mostly of plant origin The Chinese name of each drug is given, followed by the Romanised Mandarin transliteration The botanical source is then stated, whereever possible, and a note as to the composition, uses, etc, of the drug is added

Some of these substances were once familiar drugs in Europe, but have long been obsolete Many of them are still in common use in European medicine, for example, *Datura Metel*, the usual source of the valuable alkaloid hyoscine, *Hydnocarpus anthelmintica*, the seed oil of which is one of the raw materials used in preparing the derivatives of chaulmoogric and hydnocarpic acids used in the modern treatment of leprosy, rhubarb root, for supplies of which European druggists are still dependent upon Chinese collectors, and a considerable number of aromatic drugs and spices such as mint, anise, dill and ginger

The most interesting materials, however, are those which have not acquired fame in Europe, of which *Achyranthes bidentata* Blume is an example

Judging from Dr Hooper's note, the roots of this plant must be in fairly common use in China and Japan, where it is regarded as a cure for rheumatism, fever, and cutaneous diseases In Perak it is given for extreme anæmia, whilst in India and Ceylon the roots of the allied species, *A aspera*, have a reputation as a diuretic and astringent These two species belong to the natural order Amarantaceæ According to Wehmer ("Die Pflanzenstoffe") the chief economic distinction of the plants of this order appears to be that of furnishing a number of harmless and useful vegetables, whilst their most striking constituent is potassium nitrate

On the whole, therefore, it appears likely that the value of *A bidentata* in the various diseases referred to above rests on a somewhat slender foundation

A more plausible case can be made out for *Quisqualis indica*, the seeds of which enjoy a wide spread reputation as an anthelmintic, in which respect they resemble two other plants of the same natural order, Combretaceæ, namely, *Combretum quadrangulare* and *C pilosum*, neither of which occurs in Dr Hooper's list, though the first is used in Siam and the second in India Another species, *C sundaicum*, is believed to afford relief to the con firmed opium smoker suddenly deprived of his favourite drug All these plants have been ex amined at various times, and from none of them has anything likely to account for their alleged anthelmintic action been isolated, the most inter esting constituents so far as the *Combretum* spp are concerned being usually tannin or its degrada tion products or related substances Now that better methods of testing anthelmintics are being gradually worked out, it would be interesting to have some of these products tried by pharmacolo gists, as chemical methods of examination seem so far to have failed to justify native belief in their efficacy, unless, indeed, certain kinds of tannin prove to have hitherto unsuspected value as anthelmintics

We also owe to Mr Burkill's enthusiasm as a collector a monograph on the native medicines of Malaya [2] He and his colleague toured through the Peninsula interviewing the native physicians and midwives and inducing them to provide specimens of the drugs they used These, duly registered and numbered, have been placed in the herbarium of the Singapore Botanic Gardens The botanical identifications of these specimens, their Malay names, localities, and medicinal uses, are recorded in the monograph, which also includes an index to the vernacular names, with explanatory comments by the senior author

With regard to the medicinal uses it is explained that the Malays are apt to consider all sicknesses following childbirth as due to evil spirits and to place these in a special group called *sakit meroyan* To ward off such attacks they administer during the first three days after childbirth—the period during which evil spirits are most powerful—pre parations called *ubat meroyan*, and the word *meroyan* is introduced into the names of plants so used, often in highly fanciful expressions As the authors put it, an *ubat meroyan* may not be in- tended to have any immediate effect, and many of the plants in the class possess the medicinal value of sympathy, but none chemico physiologically

The number of drugs so used appears from the list to be very large These Malayan drugs include comparatively few that have found acceptance in European medicine, but many of them are well known as having a considerable reputation among natives in various parts of the world as specifics for certain tropical diseases Among these are *Quisqualis* and *Combretum* spp, the alleged anthelmintic properties of which have been referred to already Three *Alstonia* species are mentioned, including *A scholaris*, which is included in the British Pharmacopeia of 1914, apparently on account of its sup posed anti malarial action, but there is no allusion to this use in this monograph except possibly in the case of *A angustiloba* Miq, which is described as a cure for remittent fever', used by smearing the leaves with coconut oil, heating and applying hot over the spleen One of the Rubiaceæ, *Mitragyne speciosa*, is used for treating wounds, curing a craving for opium, eliminating worms in children, and reducing enlarged spleens, a truly beneficent plant, about which the authors unkindly remark that as a cure for opium craving the remedy is apparently worse than the disease This interesting plant has already been examined in Prof Barger's laboratory and it appears to merit further atten tion from the chemist and the pharmacologist

Many such examples of the value of botanical identifications as a guide to the chemist could be picked out of these useful publications, and from this point of view alone, Dr Hooper and Mr Burkill have rendered no small service in carrying out what must have been a difficult and sometimes tedious task

It is to Prof Bernard Read and his pupils in Peiping (Pekin) that we owe the introduction or if the reader prefers it, the reintroduction, of the alkaloid ephedrine into European medicine for the treatment of asthma, a piece of work which has made ephedrine in a short time one of the more important alkaloids of commerce and has led to numerous researches on the botany and chemistry of the genus [3] It is a curious fact that much of this scientific work and the resulting commercial organisation necessary for the collection of the *Ephedra* species for export to Europe and America for the manufacture of the alkaloid, have been accomplished while China has been undergoing violent political and military convulsions After much discussion it has apparently been clearly established that the two species chiefly collected in China as sources of ephedrine are *E sinica* Stapf and *E Equisetina* Bunge, and that to both of these, and possibly others, the vernacular name *Mahuang* is applied Both these species are fully described and illustrated by Prof Read, and the complicated story of their botanical identification is clearly related

There is still some doubt as to whether any of the commercial Chinese supplies are derived from *E distachya*, as Prof Read thinks there is good reason to believe this species occurs between the

Huang Ho and Yangtse Kiang Rivers, and Mr E M Holmes has had commercial material apparently derived from this source

It is a curious and disconcerting fact that when many plants of a genus have been examined, they quite frequently show remarkable differences in the character of their secondary constituents, such as alkaloids It is not surprising that five of the Chinese species, namely, *sinica*, *Equisetina*, *gerardiana*, *distachya*, and *intermedia* should contain both ephedrine and its isomeride pseudoephedrine, the former predominating in all but *intermedia*, or perhaps that E monosperma should contain a third alkaloid "Ephedrine, Spehr" and that these alkaloids should also occur in these species from India and Europe so far west as the Canaries, so far as they have been found there and examined It is, however, remarkable that of the Ephedras found in the two newer continents, America and Australia, none has so far been found to contain alkaloids Prof Read's monograph is a useful and timely summary of the present position of the botany of Ephedra, and particularly of those species which have acquired commercial importance Readers of NATURE do not need to be reminded of the valuable services which Kew renders to science and to industry, but it should be pointed out that, thanks to the work of Dr Stapf on Ephedras, Kew has been able to render very considerable assistance in solving the problems arising out of the introduction of this drug into commerce

News and Views

THE King's birthday honours list contains the following names of scientific workers and others associated with scientific activities *Baron* The Right Hon Noel Edward Buxton, Minister of Agriculture and Fisheries *Baronets* Mr Basil Mott past president of the Institution of Civil Engineers, and Mr F H Royce, founder, director, and chief engineer of Rolls Royce, Limited *Order of Merit* Prof S Alexander, in recognition of his eminent position as a British philosopher and for his services as a writer and teacher *Knights* Dr E Brown, secretary of the National Poultry Council of England and Wales, Major T H Crozier Chief Inspector of Explosives, Home Office, Prof A S Eddington, Plumian professor of astronomy in the University of Cambridge, Prof Leonard F Hill, director of the Department of Applied Physiology, National Institute of Medical Research, Dr G A K Marshall, director of the Imperial Bureau of Entomology, Prof J Arthur Thomson, Regius professor of natural history in the University of Aberdeen, Mr H W A Watson, lately Chief Conservator of Forests, Burma, Mr H Wright, chairman of the Executive Committee of the Governing Body, Imperial College of Science and Technology, South Kensington *K B E* Sir Philip Hartog, chairman of the Education Committee Indian Statutory Commission *C B E* Dr E W Smith, honorary technical adviser to the Area Gas Supply Committee, Board of Trade *O B E* Mr T P W Barty, lecturer in civil engineering, Gordon College, Khartoum, and Municipal Engineer, Khartoum, Mr J A B Horsley, Electrical Inspector of Mines, Mines Department, Board of Trade, Prof W M Roberts, professor of mathematics, Royal Military Academy, Woolwich, Dr F B Young, Principal Scientific Officer, Admiralty Research Laboratory *M B E* Mr J Haworth, general manager of the Sewage Disposal Department and Chief Chemist and Water Examiner, Sheffield Corporation, Mr H W Jack, economic botanist, Agricultural Department, Straits Settlements and Federated Malay States, Mr H G D Rooke, lately Chief Locust Officer, Ministry of Irrigation and Agriculture, Iraq, Dr A Winstanley, Junior Inspector of Mines, Mines Department, Board of Trade *C I E* Mr F F R Channer, lately Chief Conservator of Forests, United Provinces, Lieut Col H R Dutton, lately Principal, Prince of Wales' Medical College, Patna, and Superintendent of the Patna Medical College Hospital, Bihar and Orissa, Mr L Mason lately Chief Forest Officer, Andamans, Mr R R Simpson, Chief Inspector of Mines in India *C V O* Mr Evelyn C Shaw, secretary since 1910 to the Royal Commissioners of the Exhibition of 1851 *I S O* Mr D Keiller, head laboratory assistant, Imperial Institute of Veterinary Research, Muktesar, United Provinces

THE President and Council of the Royal Society have recommended Mr Ramsay Macdonald and General J C Smuts for election into the Society under the special statute which permits the election of "persons who in their opinion either have rendered conspicuous service to the cause of Science, or are such that their election would be of signal benefit to the Society" It should here be said that the inclusion of certain persons not actually engaged in scientific pursuits is a practice sanctioned by long usage In the Society's original statutes of 1663, it was provided that every one of His Majesty's subjects having the title and place of baron, or any other higher title or place, and every one of His Majesty's Privy Council, might be elected In process of time, such persons formed a panel or privileged class However, in 1873, there was much discussion on a motion to require in the privileged class, "evidence of ascertained special power and disposition to forward the aims of the Society from exceptionally personal or official advantages of position" Arising therefrom, the privileged class was limited to princes of the blood royal and members of the Privy Council Statutes enacted in 1902 abolished the clause relating to privy councillors, and the basis of qualification remains now as quoted above Its implications seem clear enough The

opportunities of the chief officer of state in the scientific arena are always at hand, they have nothing to do with political complexities

IN connexion with Mr Macdonald's nomination for election, it is interesting to recall that within the past sixty years four precedents can be recorded for the election of a Prime Minister whilst holding the seals of office The instances are Mr Disraeli, elected on Feb 10, 1876, Mr Gladstone elected on Jan 13, 1881, Mr Asquith, elected Nov 5, 1908 Mr Baldwin, elected Nov 3, 1927 The first named signed the charter book, and was formally admitted by Dr J D Hooker, the president, on June 1, 1876—fifty four years ago—that also being the day fixed for the election of the fifteen ordinary fellows Amongst these (and happily still with us) was Prof H E Armstrong Mr Gladstone was admitted on May 19, 1881 (Mr Spottiswoode was president), on which occasion William Crookes read a paper, "On Discontinuous Phosphorescent Spectra in High Vacua" It fell to Mr Asquith, in 1912, as Prime Minister, to propose "The Royal Society" at the Guildhall banquet held in connexion with the two hundred and fiftieth anniversary of the Royal Society Mr Baldwin was formally admitted by Sir Ernest Rutherford, and a similar act when extended to Mr Macdonald (following election) will provide the circumstance (we think without precedent) of the admission of two Prime Ministers during one presidency The only Prime Ministers for more than half a century who have not been fellows of the Royal Society by special election or otherwise are Sir Henry Campbell Bannerman, Mr Lloyd George, and Mr Bonar Law

PROF A S Eve's recently delivered presidential address to the Royal Society of Canada, entitled "The Universe as a Whole", essays to unite in a single view recent discoveries and theories in the physical and biological sciences and gives point to the suggestions made in our leading article this week It is pointed out that, in spite of modern specialism, "many of the great advances to day are made by those who are fortunate and able enough to be expert in two subjects, for example, in physics and in physiology, or in mathematics and physics, or in physics and chemistry, or in physics and philosophy Borderlands are prolific" This seems to prove that the wider view is not always the more superficial, hence the value of such an inclusive conspectus as the one before us Prof Eve, in dealing with recent physical theories, observes that the new quantum mechanics constitute a "far greater *bouleversement*" than the principle of relativity, though the latter has attracted more public attention Another observation of interest is that the search for ultimate nature of *substance* is probably futile and may be safely abandoned Attention is now concentrated "on the *structure*, on the form, arrangement, and resulting habits or behaviour of things" "The appeal to models is passing away, and the trust in mathematical symbols, equations, and deductions is growing stronger"

PERHAPS the most interesting passage in Prof Eve's address is the following, which occurs under the heading *Time* 'It is a remarkable fact that in physics, energy has an intimate relation with time, and also with frequency so that it is a particular fad of the author to endeavour to ascertain to what extent we can substitute the frequency of waves for the perhaps less tangible but more familiar concept of energy This is scarcely the place to enlarge on this idea, and it must suffice to point out that, as Einstein explained gravitation on a geometrical basis, so it may be possible to consider energy more fully as an aspect of frequency, possibly arriving at a comprehensive wave theory of the Universe" Prof Eve makes the observation that "It is somewhat strange to think that if the whole human species were submerged in Lake Ontario the water would rise but a few inches and doubtless the Universe as a whole would go forward but slightly affected, and dynamically and materially unimpaired" This reflection leads to the thought of the eventual extinction of humanity upon this planet, and to the ultimate degradation of energy in the universe But Prof Eve is unwilling to believe that there can be no other alternative, and quotes the remark of Prof A N Whitehead that though the universe is physically descending, yet it may be spiritually ascending At any rate, upon a question which is far more obscure than it has been represented to be, one is entitled to suspect dogmatic statements

THE annual report of the British Science Guild recently issued records a year of considerable activity The Guild was invited to give the first evidence to be heard by the Board of Trade Patents Committee, 1929, which had been appointed as a result of its activities The evidence was presented by Dr W H Eccles, Major the Hon H Fletcher Moulton, and Mr A F Ravenshear A memorandum of evidence, supplementary to the report previously issued by the Guild, is to be found in the annual report A committee of the Guild is now discussing the position of the technical expert in the public service and in industry, and in this connexion it may be noted that the Guild protested vigorously at the entire absence of scientific and technical men from the present Royal Commission on the Civil Service Further, it proposes to offer evidence before this Commission, its spokesmen being Lieut Col W H D Clark, late Deputy Controller of the Patent Office, Sir Arthur Newsholme late Principal Medical Officer to the Local Government Board, and Lieut Col W A J O'Meara, late Engineer in Chief to the Post Office The Commission will therefore have an excellent opportunity of ascertaining some facts with regard to the loss of efficiency which arises from the subordination of those who have to those who lack expert knowledge of the work of technical Departments of State

DURING the past year the Guild instituted an annual lecture to be given in honour of a benefactor, the late Sir Alexander Pedler, in a provincial town The first of these lectures was delivered at Manchester by

Dr G C Simpson, director of the Meteorological Office (see NATURE, Dec 28, 1929, p 988) The next lecture will be given at Liverpool on Oct 22 by Sir David Prain, on the subject of "Science Discipline" The third edition of the Guild's "Catalogue of Scientific and Technical Books" is announced as in the Press It has been entirely revised and enlarged, and its publication will be welcomed by the many readers of scientific literature who have found the previous editions valuable Most scientific men welcome the work which the Guild is doing, but comparatively few seem to be willing to bear a small share of the burden by becoming members On the other hand, Sir Samuel Hoare, who succeeds Lord Melchett as president, may be counted upon to bring with him new and invigorating ideas for the Guild's sphere of usefulness The new honorary treasurer is Lady Lockyer, widow of Sir Norman Lockyer, founder of the Guild and of NATURE

WHILE the Government of Great Britain is still only at the point of considering whether the creation of one or more national parks is desirable and feasible, the announcement is made (by Science Service, Washington D C) that Poland is the latest nation to have developed a national park system The largest of the Polish parks is in the Tatra range, a part of the Carpathians on the Czechoslovakian boundary, and joining with reserved areas across the borders it contributes to form a great international park covering 240 square miles The wild creatures include bear, chamois, lynx, deer, and eagles To the Polish parks has also been added the former royal Russian hunting preserves in Bialowicza, a forest some 11 500 acres in extent which formerly sheltered one of the last herds of European bison The total land reserved in Poland at the present day, for recreational and educational purposes includes six national parks, 48 forest reservations 35 steppe reservations, 13 peat bog reservations 5 lakes, and 5 interesting rock formations The national parks of Poland differ from most others in that the peasants living in them when they were established have been left there undisturbed

WE turn from those spacious parks of Poland and wonder at the seeming lack of appreciation of such places in Great Britain A Romney Marsh bird sanctuary is a possibility—a typical marsh area, frequented by rare migrant birds in winter and inhabited by a great variety of water fowl in summer In 1928 the Royal Society for the Protection of Birds purchased here an 18 acre meadow as the beginning of a larger scheme, and now the farmer owner, himself a keen bird watcher and protector, is willing to sell additional land sufficient to complete a compact reserve of 180 acres Probably no more ideal bird sanctuary, with its open water, stretches of mud, rush and reed beds, and pasture land, is to be found in any of the marshes of south east England In many another country the State would step in to form a Government sanctuary (Canada has eighty such reserves), but we have scarcely yet reached that degree of development, and private enterprise is the only alternative The amount required for the purchase of this desirable spot is £4000, of which £500 has already been subscribed, and the Royal Society for the Protection of Birds (82 Victoria Street, London, S W 1) appeals for contributions from a bird loving public to complete the purchase

IN a short article in the *Empire Review* for May, Lord Onslow reviews the steps which have been taken in various parts of the British Empire for the preservation of the native fauna If many wild creatures are to survive they must be guarded, but it need not be supposed that the enthusiasts for protection, such as the Society for the Protection of the Fauna of the Empire, seek to preserve animals in a manner likely to cause danger to life or property They do hold, however, that experience shows that the protection of the wild fauna need not interfere with development, and that preservation is in itself an asset to any country Lord Onslow rightly emphasises that if protection is to keep in touch with development its creation of sanctuaries must not be too rigid, but must permit of temporary or permanent adjustments to the needs of the animals within and the human beings outside the reserved area How rapid are the changes which may occur is illustrated by two items in Lord Onslow's article He hopes that the British Government will proclaim as a gorilla sanctuary the British territory adjoining the Belgian Park in the Belgian Congo but such a proclamation was actually made several months ago Again he refers to the success of the introduction of deer to New Zealand, but the success has turned to nuisance, and, as a note in these columns last week indicated, there is now a widespread desire for the reduction in numbers and even the extermination of the superabundant deer

ON May 30 the Halley Lecture was delivered at Oxford by Prof A S Eddington, Plumian professor of astronomy at Cambridge, before a large and attentive audience, who thoroughly appreciated the lucidity of his exposition, and the touches of humour with which it was illuminated Before embarking on the proper subject of his discourse, namely, the rotation of the galaxy, Prof Eddington remarked that in the nineteenth century attention was principally concentrated on solar motion, which had to be allowed for in estimating the value and amount of stellar motions generally The aspects which are now engaging attention are star streaming, correlation between velocity and physical characteristics, between velocity and approach towards or recession from our system, and finally the rotation of the galaxy itself The galaxy is a flattened, almost disc like system, which presents a rough resemblance to the system of Saturn's rings The solidity of the latter system was shown by Clerk Maxwell to be impossible dynamically That the rings consist of comparatively small particles rotating about a centre, the outer particles moving at a slower rate than the inner, has been confirmed by spectroscopic observation

CONTINUING, Prof Eddington said that as the stars have individual as well as rotational motion, it is necessary in investigating the motion of a system such as the galaxy, to subject a large number of stars

to observation. An attempt has been made, by using the asteroids on the analogy of Saturn's rings, to find the centre of the galactic system; an obstacle to this endeavour is the fact that the proper motions of stars in the southern hemisphere are not sufficiently well known,—"it is like flying with one wing." Prof. Eddington concluded by touching upon the many dynamical problems involved in the modern conception of the stellar universe, and the unifying influence of the hypothesis of a 'cosmic cloud' pervading space, with its attribute of viscosity. A hearty vote of thanks was accorded to Prof. Eddington on the motion of Prof. E. A. Milne, seconded by Prof. H. H. Turner, the latter of whom took occasion to refer to the need pointed out by Prof. Eddington for additional centres of observation in the southern hemisphere, in connexion with the question of the future destiny of the Radcliffe bequest.

THE National Broadcasting Company of the United States charges no licence fee for listening in to its programmes. According to an interview with Mr. James, the promotion manager of the Company, which appeared in the *Daily News* for May 28, the necessary revenue is obtained by allowing commercial companies to 'sponsor' programmes. The big business houses buy broadcasting time at the rate of £2000 an hour. Of this time not more than five minutes must be taken in telling listeners about the firm and its activities. No charge is made to universities if they desire to send out educational broadcasts, but apparently they do not take advantage of this offer. Talks are strictly limited to fifteen minutes and the silent periods must not exceed half a minute. When listeners dislike a particular type of programme they write to the company making complaints. The N.B.C. serves a great chain of seventy-six broadcasting stations stretching from the Atlantic Ocean to the Pacific. Advertisers can buy up the broadcasting time of all the stations in a particular area of the United States. It is interesting to notice that gramophone records are banned. Mr. James states that the total business turnover is about five million pounds a year. The advertising companies take up about 60 per cent of the total broadcasting time. They find that it pays to give excellent programmes. A cereal company, for example, gives children's programmes at breakfast time, and some of the largest companies give excellent classical programmes. No charge is made for broadcasting church services. In Great Britain, owing to the terms of the charter for the B.B.C., there is no advertising by radio.

THE financial difficulties by which the Australian Government is beset are acutely affecting the position of the Council for Scientific and Industrial Research. It appears inevitable that the erection of the proposed forest products laboratory in Sydney must be postponed and also that of a joint administrative block (including museum, lecture hall, and offices) for the entomology and plant industry divisions at Canberra. The contract for the main plant industry laboratories was, however, let before the present situation developed and the work will now go to completion. Plans for the McMaster Laboratory for animal health in the grounds of the University of Sydney have been adopted and building will shortly begin. The Darling Laboratory for soil science, placed in juxtaposition to the Melrose Laboratory at the Waite Institute, Adelaide, will soon be ready for occupation. While, therefore, it is apparent that the next two years will be exceedingly difficult for the Council, with little or no prospect of any extension of activity, there is reason to hope that the main lines of work initiated during the past four years will not suffer a serious set-back. A very encouraging fact is a decision just announced by the directors of the Commonwealth Bank to present a sum of £13,000 from the Rural Credits Fund to the Council to enable it to carry out certain projects which otherwise would have been abandoned, or at least seriously curtailed. £10,000 will be used in the erection of a plant house at Canberra, and £3000 will provide for insectaries for the study of blowfly and buffalo fly (*Lyperosia exigua*) problems.

IN his Friday evening discourse, delivered at the Royal Institution on May 30, Sir Harold Carpenter discussed the metal crystal. When prepared by one of the usual methods, metals and alloys consist of an aggregate of small allotriomorphic crystals and contain from about one hundred thousand to several millions of crystals per cubic inch. Their properties accordingly are the properties of aggregates and are therefore composite. In all metals, however, the individual crystal is the unit of which the aggregate is built. It is therefore the simplest form of metal. From a scientific point of view, the study of individual metal crystals should precede that of aggregates. This enables any particular property of the metal crystal itself to be studied, the only variable being its orientation. It is the realisation of this fact which has given rise in recent years to definite attempts to prepare single metal crystals. Success has been achieved in three different ways: (1) By the production of the crystal from the vapour phase; (2) by its production from the liquid phase; (3) by conversion of the solid metal in the ordinary polycrystalline aggregate into a single crystal. Each of these is an example of *controlled* crystallisation. The mechanical and physical properties of the single metal crystal are, in the majority of cases, directional. This fact is more strikingly illustrated in the mechanical tests, because the single crystal test pieces undergo distortion and assume new and striking forms. In both categories, however, the properties of the single crystal differ from those of the crystal aggregate, depending upon its particular orientation. Single crystal alloys have been investigated to a less extent but, in so far as evidence is available, it indicates that the same holds for them. Future research will involve the controlled production of single crystals in particular orientations. Such knowledge will form the basis of the scientific manufacture of metals and alloys possessing properties which can be specified with accuracy and certainty.

WE are glad to see in the report of the Board of the Institute of Physics, adopted at the annual meeting of the Institute on May 27, that the *Journal of*

Scientific Instruments continues to make progress The *Journal* publishes many valuable articles and is of decided service in the laboratory and the instrument shop There is a special section devoted to laboratory and workshop notes, and an appeal is made for increased contributions to this section from workers in laboratories, workshops, and drawing offices, etc The *Journal* is distributed to fellows at the cost of the Institute and to associates and registered students at the reduced price of 10*s* 6*d* per annum

DR W H ECCLES, in the course of his presidential address, pointed out that the Institute of Physics was incorporated in 1920 in order to form into a professional body all physicists interested in industrial applications Trained physicists had provided so many ingenious and useful weapons of attack and defence during the War that there was every anticipation of their future importance in British industry during peace Until nearly the end of the War physicists who were occasionally called upon to enter the service of the State were officially classed as 'chemists', as the word 'physicist' had not appeared in the official vocabulary, and those who had entered industry did so in the guise of 'engineers' The need for a professional Institute of Physics was evident The stability which the Institute has attained after a life of ten years shows that the founders were justified in their belief that the time had come to secure for physicists a position comparable with that of professional workers in other departments of applied science and that an organisation was required to represent them Dr Eccles was re elected president and other officers appointed were as follows, in addition to a number of members of the Board not subject to election *Vice President*, Dr R S Clay, *Hon Treasurer*, Major C E S Phillips, *Hon Secretary*, Prof A O Rankine, *Non Official Members of the Board*, Prof J A Crowther and Sir Richard Gregory

THE appointment announced last week of Prof H R Robinson to the chair of physics at East London College, will strengthen the distinguished body of physicists already associated with the University of London, and East London College may be congratulated on obtaining so distinguished a successor to Prof C H Lees, who is retiring shortly Prof Robinson was born on Nov 26, 1889 and studied at the University of Manchester, where he obtained the D Sc degree in 1917, and at the University of Cambridge, where he obtained the Ph D degree in 1924 He has been lecturer (1912–14) and assistant director (1919–21) of the Physical Laboratories in the University of Manchester, Moseley Research Student of the Royal Society (1921–23), reader and Carnegie Teaching Fellow in the University of Edinburgh (1923–26) and since October 1926 professor of physics at University College, Cardiff He was elected a fellow of the Royal Society in 1929, and has published numerous papers on radio activity, X rays and atomic structure, and similar topics in the *Proceedings* of the Royal Society and the *Philosophical Magazine*

IN recent years various heavy metals either as salts or in colloidal solution have been recommended for therapeutic purposes especially in the treatment of tuberculosis and of cancer The rationale of this treatment is the assumption that the pathological cells or tissues have a special affinity for a certain heavy metal, which thus exercises a direct toxic action on the abnormal cells in which it accumulates Thus the lead treatment for cancer introduced by Blair Bell was based on the assumption that cancer cells have a special affinity for lead It is therefore of importance to have accurate data concerning the distribution of various heavy metals after injection into an animal This problem is dealt with in a recent paper by G Hevesy and O H Wagner in which mice bearing a transplanted tumour received injections of small amounts of thorium, of lead, and of bismuth (*Arch f exp Pathologica und Pharmakologie*, vol 149, p 336, 1930)

BY the ingenious device of injecting a heavy metal together with its radioactive isotope and making electroscopic measurements with the ash of the various tissues, Prof Hevesy and Mr Wagner have overcome the difficulty of determining accurately the extremely minute quantities of the various metals which may be present in the tissues The method is of an astonishing delicacy since the amounts of tissue analysed were almost always less than 1 gm and the amount of metal found is given in units of 1/1000 of a milligram to the fourth decimal point The analyses show that neither thorium nor lead accumulates in the tumour cells If, therefore, lead has any therapeutic effect in cancer it must be an indirect one Bismuth, on the other hand, shows a striking selective accumulation in tumour cells These may contain from five to fifty times as much bismuth as the surrounding normal tissues This confirms the observations of H Kahn (*Klin Wchnschr*, vol 6, p 2335, 1927), who has used bismuth preparations in the treatment of cancer with, as he claims, encouraging results

LESS than four years ago, the Japanese Earthquake Investigation Committee, after more than thirty years of useful work, was transformed into the Earthquake Research Institute, the sole object of which is the promotion of scientific inquiries (NATURE, vol 119, p 576) The first volume of the *Bulletin* of the new Institute was published in 1926, and in each succeeding year two volumes have appeared, the last part of the seventh volume having lately reached us Some idea of the value of the new journal may be gathered from the fact that the seven volumes contain 106 papers, 1704 pages, and 198 plates In the first volume, all the papers were written in Japanese, but were provided with summaries in English or French Since then, fortunately for European readers, the number of papers in their languages has greatly increased, until in 1929 two out of every three papers were printed in English, French, or German A welcome and very remarkable feature is the extraordinary increase in the number of authors Up to 1923, the year of the great earthquake, 96 per cent of the papers in the *Bulletin* of the Earthquake Investigation Committee appeared under the name of Prof Omori In the new *Bulletin* there are papers

by 41 authors, twelve of whom are frequent contributors. While many writers continue to deal with the Kwanto earthquake of 1923 and the Tango earthquake of 1927, almost the whole field of seismology is covered. Among the more important contributions may be mentioned the mathematical investigations on wave motion by K. Sezawa, the time curves of various earthquakes by T. Matuzawa, the studies on the after-shocks of the Tango earthquake by N. Nasu, and the observations on the tilting of the ground before earthquakes by M. Ishimoto.

THE Second International Conference of Benzole Producers met in London on May 30 and 31. Delegates were present from Belgium, Czechoslovakia, France, Germany, Great Britain, Holland, Italy, Poland, and Spain, and they were received by the president, Sir David Milne Watson, president of the National Benzole Association. The Conference was opened by a speech of welcome by M. H. Laurain, president of the International Conference of Benzole Producers. Sir David Milne Watson in his address outlined the remarkable progress which has been made in the production of benzole during recent years, principally in Great Britain and Germany. Five papers were read at the Conference dealing with motor fuels for high compression engines, resin formation in motor spirits, estimation of gum in motor benzoles, the European benzole market position, and sales organisation, respectively. These were followed by a kinematograph film showing what has been done to exploit British produced benzole in Great Britain. The Conference concluded with a visit to the distribution depots, research stations, and various transport workshops of the National Benzole Company, Limited.

MR. C. C. PATERSON, director of the Research Laboratories of the General Electric Company, Ltd., Wembley, has been nominated for election as president of the Institution of Electrical Engineers in succession to Sir Thomas Purves, whose term of office ends on Sept. 30 next.

AT a recent session of the Council of the League of Nations, the Health Committee of the League was reconstituted for a further three years. Sir George Buchanan, senior medical officer, Ministry of Health, has been reappointed a member, and Dame Janet M. Campbell, also of the Ministry of Health, is a new member.

WE are informed that the Secretary of State for Scotland has appointed Sir William E. Whyte to be chairman of the Scottish Advisory Committee on Rivers Pollution Prevention in succession to the late Sir John R. Findlay, Bart., of Aberlour. Sir William has been a member of the Advisory Committee since its inception. The Secretary of State has also appointed Mr. David N. MacKay, of Messrs. MacKay, Paterson, and Chalk, solicitors, Glasgow, to fill the vacancy on the Committee caused by the death of Sir John Findlay.

THE Council of the Institution of Civil Engineers has recently made the following awards in respect of papers read and discussed at the ordinary meetings during the session 1929–30: Telford Gold Medals to Messrs. David Anderson (London) and B. B. Haskew (Weston-super-Mare); a Watt Gold Medal to Mr. A. E. L. Chorlton (London); Telford Premiums to Mr. W. T. Everall (Lahore), Prof. E. G. Coker (London), Messrs. G. L. Groves (Croydon), R. C. Bristow (Cochin), E. T. Ward (Sulina, Roumania), Gerald Lacey (Bombay), R. W. S. Thompson (Sheffield), and R. F. Hindmarsh (Newcastle-on-Tyne).

THE second Daniel Guggenheim gold medal for notable achievements in aeronautics has been awarded to Dr. Ludwig Prandtl, of the University of Göttingen, "for pioneer and creative work in the theory of aerodynamics". The first award of the Guggenheim Medal was made to Orville Wright a year ago, and the medal was presented to him in Washington on April 8 in connexion with the celebration of the fiftieth anniversary of the American Society of Mechanical Engineers. The medal is awarded by a corporation consisting of representatives of the American Society of Mechanical Engineers and the Society of Automotive Engineers, with five representatives of foreign engineering bodies, one each in England, France, Germany, Italy, and Japan.

A CLEARANCE list (No. 177) of books on entomology, geology, mineralogy, and general zoology, including mammalia, invertebrates, and ornithology, has just been issued by Messrs. Dulau and Co., Ltd., 32 Old Bond Street, W.1. Nearly 700 items are listed.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—Two veterinary surgeons under the South West Africa Administration—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (June 11). A teacher of mining and allied subjects at the Doncaster Technical College—The Secretary, Education Offices, Doncaster (June 14). An agricultural economist in the Department of Agriculture, Kenya—The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S.W.1 (June 16). A junior officer in the wood technology section of the Forest Products Research Laboratory, Princes Risborough—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (June 16). A lecturer in the Department of Mechanical Engineering of the Borough Polytechnic—The Principal, Borough Polytechnic, S.E.1 (June 16). An assistant organiser for dairy husbandry under the Wilts County Council—The Clerk of the County Council, County Offices, Trowbridge (June 18). A physicist in the Forest Products Research Laboratory, Princes Risborough—The Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1 (June 19). A part-time lecturer in philosophy and logic at Birkbeck College—The Secretary, Birkbeck College, Fetter Lane, E.C.4 (June 20). A full-time teacher of science—principally chemistry and botany—at the Shrewsbury Technical College—The Clerk to the Committee of Management of the College, Guildhall, Shrewsbury (June 21). An advisory officer in glass-house work and market gardening under the Kent

Education Committee—The Agricultural Organiser, Springfield, Maidstone (June 21) An assistant for bulb research at the Agricultural Institute and Experimental Station, Kirton, Lincs —The Principal, Agricultural Institute, Kirton, near Boston, Lincs (June 21) An instructor in building for the Government Technical Schools, Uganda—C A (T), The Secretary, Board of Education, Whitehall, S W 1, Scottish candidates, (C A), The Secretary, Scottish Education Department, Whitehall, S W 1 (June 23) A pathologist to the Cancer Hospital—The Secretary, Cancer Hospital, Fulham Road, S W 3 (June 23) An assistant in the botany and pharmacy department of the Dundee Technical College—The Secretary, Technical College, Bell Street, Dundee (June 23) An engineering workshop instructor at the Technical College, Port Elizabeth—G H Penney and Co, 23 Lime Street, E C 3 (June 24) A full time secretary of the Universities Bureau of the British Empire—The Secretary, Universities Bureau, 50 Russell Square, W C 1 (June 25) Two senior timber assistants in the Forest Utilisation Circle, Burma—The Secretary to the High Commissioner for India, General Department, India House, Aldwych, W C 2 (June 30) Two assistants on the higher technical staff of the Science Museum, one in the industrial engineering and manufactures department and one in the mechanical engineering, land transport and construction department—The Director and Secretary, Science Museum, South Kensington, S W 7 (July 4) Probationary assistant engineers in the engineering department of the Post Office—The Secretary, Civil Service Commission, Burlington Gardens, W 1 (July 10) A lecturer in charge of the Department of Zoology of the Natal University College—The Registrar, Natal University College, Pietermaritzburg, South Africa (Sept 24) A lecturer in mathematics in the University of Reading—The Registrar, University, Reading A teacher of electrical engineering at the Watford Technical School—The Principal, Technical School, Watford A secretary of the Institution of Engineers and Shipbuilders in Scotland—The Institution of Engineers and Shipbuilders in Scotland 39 Elmbank Crescent, Glasgow C 2 A chief engineer for the Manchester Steam Users' Association—The President of the Manchester Steam Users' Association, 20 Quay Street, Manchester A chemical laboratory assistant in the Experimental Department of the Fine Cotton Spinners' and Doublers' Association, Ltd —The Chief of the Department, Rock Bank, Bollington, nr Macclesfield A woman lecturer in botany and chemistry at the Studley Agricultural College—The Principal, Studley Agricultural College, Warwickshire

Our Astronomical Column

Comets —Comet 1930*d* (Schwassmann Wachmann), discovered at Bergedorf on May 2, is interesting for the near approach that it makes to the earth early this month It is evidently a periodic comet and Prof Yamamoto asks that a lookout should be kept for possible meteors from it He gives June 9 for the middle of the shower, and χ Herculis as the radiant point No accurate orbit is yet to hand, but the following by Dr A C D Crommelin, from observations on May 2, 12, 22, suffices to give some idea of it

T	1930 June 14 050 U T	
ω	192° 4′ 7″	1930 0
Ω	76 59 19	
i	17 36 32	
ϕ	43 47 17	
log a	0 51661	
log q	0 00517	
Period	5 9555 y	

The elements do not appear to resemble those of any comet previously observed

Another comet, 1930 *e*, was discovered by Mr Forbes at Cape Town on the morning of May 31, it was of the ninth magnitude, its position was R A $23^h 45^m$, South Decl 33° 38′, daily motion 4′ west, 24′ north It is too far south to be observed in England It is Mr Forbes' third discovery, in November 1928 he found a comet that had already been observed in 1818 and 1873, and in 1929 he found a periodic comet not previously observed

The Large Fireball of May 16 —A considerable number of observations have been received of this object, but they are nearly all by casual spectators of such phenomena and therefore imperfect and in some cases erroneous There is no doubt, however, as to the splendour of the object, though it appeared in the evening twilight when very few stars were perceptible Descriptions have come from Lancashire, Yorkshire, and other counties, and many interesting notes have been sent from South Wales The fireball had a long flight from east to west over the central region of England onwards to the Irish Sea, and it apparently vanished when it reached the Irish coast Pursuing a course of more than 200 miles, its height declined from 65 miles to 43 miles at a velocity of about 25 miles per second Several observers thought it was comparable in size with the moon, but this would make the object about a mile in diameter, whereas if the effects of glare and flame are eliminated the actual size would be probably about 1 or 2 feet The radiant point was in Scorpio or Ophiuchus, and it is quite remarkable that this region supplies many fireballs at various periods of the year and particularly in the spring months of May and June The great meteor of Dec 3, 1929, apparently emanated from the same region of sky, but the data were not absolutely trustworthy

The Oldest Known Star Catalogue —Most text books state that Hipparchus was the first to draw up a catalogue of stars, but it appears that in this, as in many other respects, the East anticipated the West The *Memoirs of the College of Science of Kyoto University*, vol 13, No 1, contain a paper by Joe Meta on the Chinese catalogue of Shih Shên, which he dates at about 360 B C, or two centuries before Hipparchus It is in 120 volumes, which contain a large admixture of astrology, this appears to have been one of the main motives of early celestial observations, but it had the good effect of causing careful records of phenomena to be preserved The zodiac is divided into the 28 lunar mansions, 62 northern asterisms, and 38 southern ones The identification of the stars gave much trouble, which was increased by numerous copyists' errors in the MSS The paper describes the method of dating the catalogue, which was mainly done from the recorded declinations of the stars, and closes with the list of asterisms, which gives the Chinese names and their meanings, also the extent of each The measures are in Chinese degrees, of which there are 365¼ to the circumference

Research Items.

Atmospheric Pollution.—The Report recently published for the year ending March 1928 of the Atmospheric Pollution Research Committee of the Department of Scientific and Industrial Research is a quarto pamphlet of 68 pages, 40 of which are occupied by tables. The majority of the records are obtained by means of a glazed earthenware or glass funnel on the sides of which solid particles from the air deposit themselves and are washed by rain into a bottle placed below. Each month the contents of the bottle are analysed and the tons of deposit per square mile calculated. Rochdale has 13 of these gauges, London 11, and Glasgow 9. At Rochdale one gauge is placed at the centre of the town and the others within a mile of the centre. The average deposit per month is 33 tons per square mile, of which 15 tons are soluble. London has one station at which the deposit is about as heavy as that at the worst of the Rochdale stations, but stations at Kew and Victoria Park reduce its average to about 70 per cent of the Rochdale average. Glasgow has no station at which the deposit reaches 70 per cent of the worst London and Rochdale stations and its average is about 72 per cent of the Rochdale average. Rothamsted, Southport, and Kingston upon Thames get about a third of the average Rochdale deposit.

Chinese Mammals.—Since no attempt has yet been made to compile a list of all the mammals found in China, N. Gist Gee has made a praiseworthy and useful effort to gather together, without detailed specific revision, the records which so far have been made (*Peking Soc. Nat. Hist. Bull.*, vol. 4, p. 49, 1930). In the circumstances, the list cannot be regarded as perfect, but its value is obvious as a groundwork upon which future investigations of the mammalian fauna can be based. The list, which includes sub-species, gives one or two references to literature in each case and states the provenance. It covers 42 pages and comprises round about 700 species and sub-species.

External Parasites of British Birds.—A short but useful paper by R. S. Bagnall and W. Hall, written in 1912 and only now published (apparently without further editing) gives a list of mallophaga identified from some British birds (*Vasculum*, May 1930). Fifteen species of birds are dealt with here and the need for the examination of their lice is apparent in the nineteen species which are recorded for the first time as British, while species from the fulmar petrel and the little auk are new to the fauna of Europe. It is a remarkable and significant fact that the lice from these two British birds belong to species which have hitherto been found only on related species on the Californian coast.

Researches on Earthworms.—*Pheretima* is a genus of earthworms much used for experimental study in Japan. In the *Science Reports of the Tôhoku Imperial University* (Fourth Series (Biology) Sendai, Japan, vol. 4, No. 4, December 1929) there are two papers on this subject, the first by Hideomi Tuge, "On the Number of Ganglion Cells in the Suprapharyngeal Ganglion and in the XXX Ventral Ganglion of the earthworm *Pheretima megascolidioides* (Goto and Hatai)", the second by Teruhei Hino, on "Carbon Dioxide Production in relation to the Growth of Body of earthworm *Pheretima communissima* Goto et Hatai." *Pheretima megascolidioides* measures 1½ feet when fully extended and is well adapted for experimental study. It was found that the number of ganglion cells in segment XXX was considerably larger than in the corresponding segment of smaller species previously used. In the suprapharyngeal ganglion one pair of nerves is associated with more than twice as many cells than the pair of nerves in the ventral ganglion. Mr. Teruhei Hino, who reared his worms from eggs, states that the gaseous metabolism in *Pheretima communissima* bears a direct relation to the body surface, and the carbon dioxide production per sq. cm. per hour is constant during the greater part of the growing period. When the sexual organs begin to develop the rate rapidly increases, to fall again after the breeding period.

Myriopoda of the Swiss National Park.—Dr. W. Bigler in an elaborate memoir has described the Myriopoda Diplopoda in the region of the Swiss National Park ("Die Diplopodenfauna des Schweizerischen Nationalparks". Ergebnisse der wissenschaftlichen Untersuchung des schweizer National parks, herausgegeben von der Kommissionen der S. N. G. zur wissenschaftliche Erforschung des National parkes, December 1928 (1929)). This is specially a study in distribution and in the region which embraces various habitats including much high land, we find a large number of Myriopods belonging to the groups recorded. Besides the actual National Park reservations, neighbouring localities were also studied for comparison. Each genus and species is carefully described with details which affect their systematic position, especially the auxiliary copulatory apparatus of the male, which is of considerable importance in classification. Many species are found so far up as 2800 metres, those from the greatest heights belonging to the Julidæ and Ascospermophora. Between 1300 metres and 2800 metres the maximum occurs at about 2100 metres, the woodland limit being at 2200 metres. The largest numbers belong to the Glomeridæ, which range from 1450 metres to 2700 metres, and the Julidæ (having the widest range), from 1300 metres to 2800 metres. The work is of much interest and greatly extends our knowledge of distribution and habitat of the Diplopoda.

Australian Fisheries.—A map of the fisheries of Australia, prepared by the Development and Migration Commission for the information of the members of the Australian Fisheries Conference, has recently been issued by the Australian Government. Several attempts have been made to discover suitable trawling grounds around the coast especially in the south, and the positions of these explorations have been indicated by coloured signs. The most important work of the kind was that done by the Federal Investigation Ship *Endeavour* between 1909 and 1913, but it was not continued after the unfortunate loss of that ship. A series of notes is printed on the map containing information on the present position of the fishing industry in Australia, and these notes, used in conjunction with the map itself, give a clear indication of what has already been done and of the developments which are immediately called for. The map, which in addition to fishery information gives isotherms showing air temperatures over the land, as well as sea temperatures, has been well reproduced by the Hydrographic Branch of the Navy Office at Melbourne.

Standardisation of a Plate Method of Counting Soil Actinomyces.—The study of the Actinomyces group of micro-organisms is as yet in its infancy, but enough is already known to indicate that these fungi play a very significant rôle in Nature—either as injurious

parasites to animals and plants, or as beneficial saprophytes which help to break down complex organic matter to humus in the soil It is in the latter rôle that a special interest now attaches to them One of the greatest difficulties in estimating the activities of the Actinomyces in the soil has been that of counting their numbers, since no two of the culture media in general use yield results which are at all comparable Messrs M Ganesha Rao and V Subrahmanyan (*Jour Ind Inst Sci*, vol 12A, part 18, pp 253 273) have done mycology a great service in comparing the variable counts obtained by the use of a considerable number of standard media, and in evolving a new synthetic media which gives maximum and consistent results This is the type of problem which by reason of its laborious and unimaginative character is usually avoided by research workers Its results, though simple, are often of more fundamental service to science than those of more spectacular problems, and we congratulate the authors on having carried the present one to a successful conclusion

Cotton Yield and the Flowering Curve—Mr N W Barritt has an interesting discussion of the possible correlation between the production of flowers by the cotton plant and its subsequent production of cotton in the *Empire Cotton Growing Review* vol 7, April 1930 He points out that Egyptian workers on cotton have a general impression that the ideal plant should have a steep and narrow flowering curve, so as to ensure an early crop capable of being picked almost in one operation 'This belief appears to be based chiefly on the fear of the pink boll worm, notwithstanding the fact that Williams in 1926 showed conclusively that the increase in the boll worm always kept pace with the growth of the crop" Barritt examines some yields given by C H Brown for two new strains of cotton grown side by side in four different localities in Upper Egypt Both strains give identical flowering curves which are very different in the different localities, and in both strains the broad flat flowering curve is definitely superior to the short steep curve Barritt suggests very reasonably that this is because, with the steep flowering curve, most flowers open on the same day, and if these bolls afterwards ripen, such bolls are competing more intensely for the available carbohydrates, with, as a result, some starvation of the developing lint

Cultivation of the Castor Oil Plant—Castor oil with its capacity for remaining liquid at low temperatures whilst it retains its high viscosity at high temperatures, has proved of great value as a lubricant in internal combustion engines, and especially in aeroplane engines It is also used in the dye industry, in the manufacture of Turkey red, whilst the pure cold-drawn oil, which is free from the poisonous ricin contained in the seeds, is of course employed in medicine as a purgative Its usefulness as a lubricant, particularly, points to an extension of its employment, and though the plant is scheduled in parts of New South Wales and Queensland as a 'noxious weed', there is probably good reason, in many tropical and sub tropical regions, to consider carefully the possibilities of *Ricinus communis* as a crop The plant is singularly variable in cultivation, yielding profusely in some places, whilst in apparently similar situations nearby, it may be very disappointing The suitability of the plant for unused pieces of land, on the borders of cultivation, in refuse heaps and other waste spots, together with the ease with which the seed can be collected, make it almost an ideal crop for the small cultivator, or as a catch crop in permanent cultivation, provided that local conditions provide a good market for comparatively small quantities of seed The habit of growth and method of cultivation of the plant, together with methods of oil extraction, etc, are dealt with fully in an article in the *Bulletin of the Imperial Institute*, vol 28, No 1, 1930 At present, India is the chief source of the world's commercial supply of castor oil, but instead of the primitive method of expressing the oil used in India, the seeds are tending more and more to be exported, especially to England and America Brazil is also exporting both castor seed and oil

Japanese Tectonics—In the *Jap Jour Geol and Geog Trans*, **7**, No 1, 1929, S Yehara publishes the results of nine years' study of the geology and tectonics of Shikoku together with a beautifully printed geological map of the island and a map of the Japanese Islands illustrating tectonic movements during the Cainozoic The dominant fracture belt is the 'Median tectonic line' which came into existence in south west Japan about the close of the Triassic All the pre Tertiary rocks have been affected by movements exorted from the north (Lower Triassic and post Jurassic) The north east–south west trend lines of the Cainozoic are referred to the 'peri Setouchi' movement The trend lines of Kyushu and the Riu kiu festoon are similarly referred to the 'peri Iunghai' movement The two arcs cross in the extreme south west of Japan and in the straits between Kyushu and Korea To the west and north the trend lines are very different In addition to the volcanic line of the Bonin Islands, there are the mountain ranges of Abukuma and Kitakami (in the north of the main island) and of Hidaka (in Hokkaido) All these extend north north west to south south east The horizontal pressure responsible for the movements is regarded as having come from the east, that is, from the Pacific, and is referred to the 'peri Tuscarora' movement

Investigation of Electrolytic Dissociation by the Raman Effect—A paper by Dr I R Rao in the May number of the *Proceedings of the Royal Society* gives further details of his work on the Raman spectra of nitric acid A modified form of Prof R W Wood's apparatus was employed, and both the origin of the ten sets of Raman lines established, and the relative intensities of a number of the satellites measured by means of a microphotometer, to obtain quantitative information about the numbers of NO_3 ions and undissociated HNO_3 molecules responsible for the scattering The change in the degree of dissociation with progressive dilution could then be followed on the assumption that the intensity of the scattered light at 4567 A was proportional to the number of free ions present Extension of this work should permit of a decision between the alternative theories of complete dissociation at all dilutions and progressive dissociation with increasing dilution, at least in the case of this particular strong electrolyte

Liberation of Electrons by Positive Ions—A form of apparatus for investigating the liberation of electrons from metal surfaces by positive ions is described by M L E Oliphant in the May number of the *Proceedings of the Royal Society* The problem is complicated by the fact that the most convenient source of ions, an electric arc in gas at rather low pressure, must be in direct connexion with the chamber in which the ions are made use of, and the latter must be kept at very low pressure, so that differential pumping must be employed In Dr

Oliphant's work the ions were drawn from a helium arc through a positive ion sheath on to an auxiliary electrode, which collected most of them, but allowed a few to pass through a small hole to a second chamber. There they were sorted out from metastable atoms, given the desired speed, and allowed to impinge on a target. The electrons set free from the latter were analysed by a retarding field, or magnetically, the system of electrodes used in the second method being particularly ingenious and delicately mounted. Dr. Oliphant has obtained a considerable volume of valuable data, and has been able to show, in a second communication in conjunction with Mr. P. B. Moon, that all essential features of his results agree well with current ideas of the electrical structure of metallic surfaces.

Electrometric Hydrogen Ion Measurements.—Measurements of the hydrogen ion concentration of solutions are being recognised as of increasing importance not only in many fields of research but also in nearly every industry. To those who have not yet installed an electrometric apparatus for this purpose the Cambridge Instrument Company's new list (No. 108) of instruments will be welcome as a guide to the selection of a suitable equipment. The general designs are along well tried lines and the following comments refer only to the more novel features. The potentiometer recommended for the highest accuracy has a selector switch so that measurements on three different solutions can be carried out in rapid succession. For more general and industrial work there are two self-contained portable potentiometers embodying Unipivot galvanometers with standardisation from either the galvanometer itself or, in Mr. S. W. Cole's pattern, from a Weston standard cell built into the instrument. The second pattern may be used with either a dry battery or an accumulator and has additional scales giving temperature corrections and direct readings of pH values. Dr. P. T. Kerridge's glass electrode outfit with a Lindemann electrometer has advantages where only small amounts of solution are available or where the hydrogen and quinhydrone electrodes are disturbed by oxidation or reduction. A recording potentiometer in conjunction with double quinhydrone electrodes is used to record pH values automatically and to give audible warnings when critical values are reached. The list includes a brief discussion and bibliography of typical industrial and research applications.

Formation of Iron Pentacarbonyl.—By the examination of the contents of a steel cylinder containing compressed coal gas which has been standing since 1899, Friend and Vallance found that considerable amounts of iron pentacarbonyl $Fe(CO)_5$ had been produced. The pressure of the gas was probably between 50 atm. and 80 atm. The observations are recorded in the April number of the *Journal of the Chemical Society*; other recent researches noticed in NATURE also show that small quantities of iron carbonyl may be formed from carbon monoxide under pressure in steel cylinders during a period of a few weeks.

Chlorides of Sulphur.—Attention has been directed in previous notes to the investigations of Lowry and his collaborators on the chlorides of sulphur, the compounds S_2Cl_2, SCl_2, SCl_4, and S_2Cl_4 having been described. The researches have been extended by Lowry and Jessop, in the April number of the *Journal of the Chemical Society*, in which measurements of the dielectric constants of sulphur chloride mixtures over a range of composition from monochloride to chlorine and from room temperature down to the freezing points are described. The isothermals for the liquids confirm the existence of sulphur dichloride but do not show any inflection corresponding with the tetrachloride, even at $-50°$. The dielectric constants of the solids, however, show a pronounced maximum at the composition of the tetrachloride, indicating, in agreement with previous work, that this compound exists in the solid state.

Structure of Strychnine and Brucine.—In the Bakerian Lecture delivered before the Royal Society on May 29, Prof. Robert Robinson, Waynflete professor of chemistry in the University of Oxford, discussed the experimental evidence which is available for the development of structural formulæ for the highly complex molecules of the alkaloids strychnine and its dimethoxy derivative brucine. From a study of the products of electrolytic and catalytic reduction, of nitration and oxidation, and so on, it has been possible to draw numerous conclusions which go far to establish the orientation of the various groupings in the two molecules. Thus strychnine, which possesses the molecular formula $C_{21}H_{22}O_2N_2$, appears to be a polycyclic compound, which contains (*a*) an ethylene linkage, (*b*) an etheric oxygen atom, which is almost certainly a member of a heterocyclic ring, (*c*) a tertiary basic nitrogen atom, (*d*) a cyclic amide group $>N \cdot CO \cdot CH_2$—, in which the nitrogen atom forms part of another heterocyclic ring, and (*e*) a benzenoid ring, to which this second nitrogen atom is directly attached. It is this aromatic nucleus which carries the two methoxyl groups in the molecule of brucine. A structural formula expressing the ascertained facts with a high degree of probability is given in Prof. Robinson's paper.

Inductive Interference in Telephone Circuits.—The troubles that arise owing to the inductive interference of power transmission lines with telephone circuits were discussed by Colonel Sir T. F. Purves, the engineer to the Post Office, in an interesting speech at Sheffield on Feb. 19 to the local section of the Institution of Electrical Engineers. He mentioned that the Comité Consultatif International des Communications Téléphoniques à Grande Distance (C.C.I.) has for some time been studying how to protect communication circuits both from inductive interference and from electrolytic action due to neighbouring power lines. The C.C.I. has issued a set of guiding rules to minimise inductive interference and to fix limits for the maximum disturbance permissible. There were, however, several outstanding problems which were being investigated by another international body, the Commission Mixte Internationale (C.M.I.). The most important problem at the present time is the dangerous inductive effects which occur in communication circuits when a fault arises on a high tension transmission line. 'Acoustic shock' is generally caused when a voltage sufficiently high to operate the lightning protectors (about 350 volts) is induced in the two wires of the telephone circuit. The lightning protectors which are on each side of the circuit do not act simultaneously. The charge consequently passes through the operator's set and the diaphragm of the telephone receiver is brought into violent contact with the pole pieces. The ear of the listener can be permanently damaged in this way. Even if it is not, frequent disturbance of this kind affects the nerves of listeners. In the case of operators, the loss of morale is often so serious that continued work becomes impossible. Sir Thomas Purves stated that in Germany and America the trouble due to this cause is very serious. The British Post Office has adopted 300 volts as the maximum permissible induced longitudinal voltage possible in a circuit, but it is very difficult to predict by computation

The Physical Society's Discussion on Magnetism

THE discussion on magnetism organised by the Physical Society and held on May 23, at the Imperial College of Science and Technology, admirably illustrates the thesis that with advancing knowledge our concepts of a particular region of Nature, even though they may serve to correlate a wider range of phenomena, become less clear cut and more diffuse and difficult to follow

When Sir Alfred Ewing formulated his magnetic models, our knowledge (in great measure due to his own happily conceived experiments) was confined mainly to the properties of the ferro magnetic elements, and that knowledge could be subsumed under certain relatively simple concepts Sir Alfred, in his opening address, reminded us that his own model, though not to be regarded as anything more than a piece of symbolism, could still assist in clearing our views concerning certain ferro magnetic properties He illustrated this position by instancing a criticism of the model made by Swinburne, who pointed out that its behaviour indicated the unlikely condition of a zero hysteresis loss in a revolving field strong enough to produce saturation Though the fact has almost escaped notice, experiments by Baily on the hysteresis loss in a revolving field have shown that the loss increases with increasing field strength to a maximum and then does fall almost to zero when the field is strong enough to produce saturation

About the beginning of this century, Curie's investigations, developing the fundamental observations of Faraday had resulted in the well known generalisations that the mass susceptibility of a diamagnetic was independent of the temperature, and of a paramagnetic varied inversely as the absolute temperature The concept of the magneton was shadowed forth so far back as the eighteen seventies by Weber, in a model identical with that of simple electron theory, save that the rôles of the electricities are reversed Weiss gave the name to a fundamental unit of magnetic moment obtained from a study of the mass susceptibility per gram atom, and a knowledge of Avogadro's number, the number of atoms in the gram atom Such atomic magnetic moments were always found to be integral multiples of a fundamental quantity, the Weiss magneton, $18\ 54 \times 10^{-22}$

It is easy to calculate by the classical laws, the magnetic moment of the magnet competent to produce the field due to an electron revolving in a circular orbit about a central nucleus Writing down the angular momentum of the circulating electron, taking the ratio of the magnetic moment to the angular momentum, and in terms of the quantum theory assuming the angular momentum to be an integral multiple of $h/2\pi$, we easily find in the simplest case that the magnetic moment of the Bohr magneton is $he/4\pi m$, which, by substitution of known values, gives the magnetic moment of the Bohr magneton as almost exactly five times that of the Weiss magneton The properties of a 'ring' electron, in which the revolving charge, instead of being concentrated at a point, is uniformly distributed over a thin anchor ring, have from time to time been discussed, and it is interesting to note that some of Schrödinger's recent results are strictly analogous to those obtained for this ring type of magneton

Langevin's classical paper of 1905 gave a basis for Curie's experimental generalisations concerning the behaviour with temperature of dia and paramagnetic bodies Again an appeal is made to classical methods The electron orbit behaves as a magnet and possesses a magnetic moment It is possible that, for a given molecule, these orbital moments give no resultant magnetic moment The application of a field which rises from zero to some final value, H, will cause a change in the magnetic moment which can be calculated on the assumption that an electromotive force is induced in the orbit, measured by the rate of change of the flux through it It is not difficult to show that this change is negative In a paramagnetic gas we have to deal with molecules which have a resultant magnetic moment, and, assuming an initial random distribution of the axes of these magnets, it may be shown that the application of a magnetic field results in the development of a magnetic moment giving a mass susceptibility varying inversely as the absolute temperature

So far the effect of any mutual molecular interaction has been neglected, but if, following Weiss, we assume the existence of a molecular field proportional always to the intensity of magnetisation, I, so that the total field is $(H+NI)$, we then obtain for the mass susceptibility the modified Curie law, which makes the susceptibility inversely proportional, not to T, but to $(T-\theta)$ But considerations of the Zeeman effect show that Langevin's original treatment of paramagnetism requires serious modification, inasmuch as we find that only certain discrete values can be assumed by the resolutes, in the field direction, of the atomic magnetic moments, and in order to resolve the difficulties of the situation it is necessary to endow the electron with an intrinsic spin and a magnetic moment

These elementary considerations and many more points of importance in modern theory are developed in the contributions made to the discussion by Dr E C Stoner and by Prof H S Allen

Prof C G Darwin discussed the polarisation of the electron The quantisation of the electronic orbit leaves unexplained certain finer phenomena which are covered by giving the electron itself an intrinsic spin, and now with the development of wave mechanics comes the notion that the electron can be considered as a polarised wave Prof Darwin considered in some detail the possibility of observing directly the magnetic moment of a *free* electron, as distinguished from the indirect verification observed by loading the electron with the core of a silver atom and subjecting the stream of atoms to the action of a non uniform magnetic field as in the experiments of Gerlach and Stern

Bohr has suggested that any experiment of this type carried out on streams of free electrons would necessarily give negative results, as the electrons would have uncertainties of position and speed which would blot out any systematic effect which we might hope to obtain Prof Darwin disagrees with this conclusion, based as it is on the assumption that the behaviour of the polarised electrons is observed by *one* magnetometer, whereas a survey of the magnetic field by several magnetometers may enable us to overcome the uncertainty

Mr W Sucksmith discussed some difficult experiments on the measurement, for ferro and para magnetics, of the gyromagnetic ratio—the ratio of the magnetic moment of the magneton to its angular momentum—a knowledge of which leads to an estimate of the Landé splitting factor g For the Dy^{+++} ion in Dy_2O_3 he finds for g the value $1\ 28 \pm 7$ per cent, the theoretical value being 4/3

Prof W Peddie's contribution dealt with the interrelations of magnetisation and temperature in crystals from the point of view of kinetic theory He showed that a good general account of the phenomena can be given by a reduced equation of state of the second degree Dr W L Webster gave an account of magnetostriction and change of resistance in single crystals of iron and nickel, showing that there are two

stages in the process of magnetisation which involve different distortions of the crystal

Dr L F Bates described some experiments on the temperature variation of the specific heat of manganese arsenide, which has a critical temperature in the neighbourhood of 45° C The hypothesis of an internal field, put forward by Weiss, leads to a definite shape for the specific heat temperature curve, and Dr Bates finds that while the general form of the curve is similar to that given by the Weiss theory the variation of specific heat with temperature is more nearly proportional to dI_s/dT than to dI_s^2/dT

Mr F C Powell dealt with the change in size of a ferro magnetic at the Curie point A rough estimate of its magnitude has already been made for iron on Heisenberg's theory, but the experimental values had been misquoted The present paper corrects this and also revises the theoretical estimate in the light of Heisenberg's modified theory The numerical values for iron and nickel are calculated and are found to be of the order demanded by the theory

Prof Weiss and M Forrel gave the results of an experimental study of the saturation data for a number of ferro cobalts and nickel cobalts and deduced therefrom the atomic moments of iron, nickel, and cobalt

The paper by Prof W Gerlach is an experimental study of the relation between certain electrical and ferro-magnetic properties Nickel is the substance under investigation and its change of resistance with temperature has been studied over a range which includes the Curie point The curves showing the variation with temperature of the *temperature coefficient* of the resistance are in very close agreement with the curves obtained by Weiss for the variation of specific heat with temperature Prof Gerlach further discusses the resistance change of nickel in a longitudinal field and describes a new thermo magnetic effect If a ferro magnetic body is placed in a homogeneous magnetic field, and a temperature difference is established between its ends, the lines of force of the field coinciding in direction with the line of temperature fall, an e m f appears between the ends of the body Prof Gerlach describes preliminary experiments on the variation of this e m f with variation of the temperature at the ends of the specimen

It need scarcely be said that Dr P Kapitza's account of his remarkable experiments in strong fields was full of interest, and it is not too much to assert that a technique which has placed in the hands of experimenters a method for developing fields of 300 kilo gauss in a volume of 3 cubic centimetres, even though the duration of the field be a hundredth of a second, represents one of the most important advances in experimental work that the last few years has afforded The magnification of the ordinary effects observed reaches such large values that the short space of time in which the effects are observable introduces no unsurmountable difficulties Thus the splitting of the lines in the Zeeman effect is so large that it may be observed by means of the ordinary prism spectrograph, and changes of electrical resistance which in ordinary fields require very special methods for their estimation are, in these large fields, increases of 20 or 30 per cent

The whole discussion was thoroughly enjoyable If it tended to show that modern magnetics, in some of its aspects, is still in a pre Newtonian stage, where it is dominated by

> "Cycle on epicycle, orb on orb,
> With centric and eccentric scribbled o'er,"

it has cleared up some difficulties, focused attention on others, and has certainly helped to systematise the ideas of many of those who were present

ALLAN FERGUSON

Utilisation of Potatoes

A PRACTICAL account showing how potatoes can be used most profitably at present prices is given in the *Scottish Journal of Agriculture*, vol 13, p 30 Both potatoes and oats have a high feeding value, and on farms carrying stock it is being found more economical to use them for food than to sell them The quantities that can be safely used, their relative food values and costs, are compared with those of other commonly used food stuffs, data from actual feeding experiments being quoted in support of the recommendations

Cattle can utilise potatoes raw, but for pigs they are better cooked, green or sprouted tubers should be avoided as they are liable to be harmful Since the protein and mineral content of potatoes is low, a supplementary ration such as separated milk and a mineral mixture is necessary for young animals or dairy cows On a ration containing a large proportion of oats and boiled potatoes so supplemented, young pigs gave as good gains, at lower cost, as when raised on other commonly used food stuffs

The question as to the best use to make of surplus potatoes is also discussed One of the chief difficulties lies in the fact that the surplus is a casual one, depending on seasonal conditions, although importation of foreign potatoes and overplanting contribute to the problem The possible uses, other than human consumption, to which potatoes can be put are various Feeding to stock, either whole or as silage is probably the simplest way of dealing with the surplus, but silage making needs further investigation and development in England Alcohol starch, acetic acid, or dried potatoes are successfully produced from potatoes on the continent, but so far little has been done in this direction in Great Britain The fluctuating supplies of raw material present a special difficulty in establishing such industries

Increasing the demand by selection for cooking quality rather than yield, increased export of seed, improved grading and better marketing, especially in early summer when imports are greatest, are further means by which the surplus may be reduced In fact, better organisation, together with a diversion of the surplus into channels other than for human consumption, is necessary to make potato growing in Great Britain remunerative and a trustworthy source of profit

New Short-Circuit Testing Plant

WE are glad to notice that the number of commercial testing laboratories in Great Britain is rapidly increasing As a rule these laboratories are not co operative but are set up by individual companies In the *Electrical Review* for May 30 there is an interesting account of a short circuit testing plant which has been erected by Messrs A Reyrolle and Co, of Hebburn on Tyne

The plant has the short circuit capacity of 1,500,000 kilovolt amperes and is the largest plant of this kind in Great Britain It is situated at Reyrolles' New Town Works between Newcastle and South Shields As large devices have to be tested, in some cases until they break down and are destroyed, and as huge amounts of electric energy are suddenly converted into heat, great precautions have to be taken to prevent fire Cylinders filled with carbon dioxide are stored in the transformer room The gas can be released by a switch in the control house or locally by hand and the machine and terminal pit are at once flooded with the gas

In one of the tests an oil tank containing a hundred gallons of switch oil was heated to 140° C It was ignited by means of wood and waste soaked in eighteen gallons of petrol and paraffin The tank was then upset, and after sufficient time had been allowed to elapse to ensure that the oil was well ablaze the test bay door was closed and the carbon dioxide was released by operating the switch at the control house The time that elapsed between the decision to close the door and the complete extinction of the fire was fifteen seconds After about five minutes the door was opened again and the smoke and gas were allowed to dissipate The damage done was negligible and consisted only in a slight blackening of the lamp shades, control switches, and other apparatus in the test bay

We congratulate Messrs Reyrolle and Co on having constructed what is practically an electric power supply station capable of giving for testing purposes an infinite variety of electric loads reproducing the equivalent of the momentary outputs of our largest power stations

University and Educational Intelligence

CAMBRIDGE —The Appointments Committee of the Faculty of Geography has reappointed Mr J A Steers, of St Catharine's College, to be University lecturer in the Faculty

J S L Gilmour, of Clare College, has been appointed curator of the Herbarium and Botanical Museum

The Council of the Senate has appointed Mr H M Combie of King's College, a member of the Consultative Council of University and School Science Teachers

D J Watson, of Downing College, has been reappointed to the Frank Smart University studentship in botany

A course of instruction in the technique of tissue culture will be given at the Strangeways Research Laboratory on July 1 29 Only a limited number of applicants can be received Notification from those wishing to take the course should be sent to Dr H B Fell, Strangeways Research Laboratory, Cambridge

EDINBURGH —Sir James Barrie has been elected Chancellor of the University, in succession to the late Lord Balfour

LEEDS -The foundation stone of the new library of the University will be laid on June 24 at 3 P M by the Lord Brotherton of Wakefield, donor of the library building, the Chancellor, His Grace the Duke of Devonshire, will preside

OXFORD —The report presented to Congregation by the curators of the Parks mentions the progress that has been made in labelling the trees, a most welcome and desirable addition to the opportunities afforded by the University for botanical study and observation

NINE scholarships, each of the annual value of £25, have been founded at the Constantine Technical College, Middlesbrough, by the Imperial Chemical Industries, Ltd Forms of application for the scholarships, returnable by at latest June 16, may be obtained from The Director of Education, Education Offices, Middlesbrough

THE Royal Commissioners for the Exhibition of 1851 have made the following appointments to Senior Studentships for 1930, the recommending body being given in brackets Dr J Farquharson (University College, London), for research in physical chemistry, Dr M Ritchie (Edinburgh), for research in chemistry, Dr L Rosenhead (Leeds), for research in aerodynamics and geophysics, Mr C P Snow (Cambridge), for research in physical chemistry

Two or three years ago Mr G H Bosch gave £222,000 to the University of Sydney for the establishment of chairs in the Medical School and for building and equipment of laboratories Announcement is now made by a Reuter telegram from Sydney that the Rockefeller Foundation, no doubt following its usual practice of supporting local benefactions, has agreed to contribute £100,000 to provide laboratory facilities at the University for the departments of surgery, pathology, bacteriology, and allied subjects

THE twenty first Annual Conference of the Association of Teachers in Technical Institutions is being held at Brighton on June 6–10, under the presidency of Mr H A Norman, head master, Junior Technical School, Bury An exhibition of apparatus and books will be held in the Royal Pavilion, Brighton, on June 9 and 10 Among the topics for discussion are liaison between Government departments concerned with education schemes, interchange of teachers, Yorkshire Council for Further Education National Certificates in building, university service and superannuation, Royal Society of Teachers, and junior technical schools

VACATION courses for teachers and students in England and Wales have been arranged by the Board of Education, local education authorities, university bodies, and associations of teachers and others, to be held this year, chiefly in July and August, in London (19), Oxford (11), Cambridge (6), Bournemouth, Brighton, Seaford, Folkestone, Herne Bay, Saltburn by Sea, Scarborough, Bangor, Aberystwyth, Barry, Malvern, and other places Particulars of these and of courses for teachers at Dundee, Glasgow, Aberdeen, and Edinburgh are contained in the Board of Education's recently issued pamphlet on the subject (H M Stationery Office, 6*d*) The sciences, especially biology and psychology, figure prominently in this prospectus The Brighton Education Committee, one of the six education authorities offering vacation courses has concentrated on biology to the exclusion of other subjects The course, on Aug 1–15, will be conducted by Dr W D Henderson, head of the department of zoology in the University of Bristol, and will include practical work and collecting in the field, with demonstrations on the material collected It is intended for teachers of biology who prepare pupils for the first and higher school certificate examinations Twelve university tutorial classes committees offer courses organised in connexion with the work of the Workers' Educational Association All except one include psychology in their programmes The Association of Women Science Teachers is holding a course in botany at Leeds and in chemistry at Bedford College, London Courses for foreign students are provided by the Universities of Oxford, Cambridge, and London (2), by University College, Exeter, the College of Preceptors, and the Regent Street Polytechnic, London For particulars of the arrangements by which British and foreign students attending recognised vacation courses in Great Britain can obtain reductions in railway fares on the British railways, application can be made to the National Union of Students, 3 Endsleigh Street, London, W C 1

Historic Natural Events

June 8, 1918 Nova Aquilæ.—On this date Nova Aquilæ III was discovered independently by a number of observers when it had suddenly become a conspicuous star. On June 9 its brightness nearly equalled that of Sirius, it then began to fade and eight days after its maximum it had decreased to one fiftieth of its maximum brightness, while eight months later it was invisible to the unaided eye. It was found that, during the thirty years prior to 1918, a faint star had been photographed many times in the place occupied by the Nova, a star which afterwards increased in apparent brightness about 30,000 fold within four days. Telescopically the Nova remains as a variable star enveloped by an expanding shell of nebulosity which, apparently originating at the time of the sudden brightening, spread outwards radially with great velocity and was first visible in large telescopes six months later. The early recognition of this Nova enabled a unique spectroscopic study to be made of it in the early phases of its outburst which, appearing to us in 1918, actually occurred about the eighth century.

June 9, 1888 Waterspout.—A peculiar funnel shaped cloud approached the village of Langtoft, Yorkshire, from the eastward, and burst over the hills to the westward. An enormous volume of water flowed down the hill, forming three parallel fissures in the chalk, in the deepest of which were four holes seven feet deep. The water then flowed into the village in a stream 40 feet wide and three or four feet deep, entering the houses and doing great damage, though no life was lost.

June 9, 1905 Luminous Cloud.—About three quarters of an hour after sunset a luminous cloud was observed over the greater part of New Zealand, probably the trail of a meteor. At first it appeared as a long streak, gradually becoming Z shaped. For more than twenty minutes it was brighter than the moon, then its glow became diffused and fainter, but it retained a glow equal to that of the zodiacal light for ten minutes longer.

June 9, 1910 Thunderstorms.—A series of violent thunderstorms occurred over England on June 7 and 9, 1910. On June 7 they occurred between 6.30 and 11.30 P.M., along a belt of country from Surrey to central Wales. On June 9 they occurred over the southern half of England and were accompanied by torrential rain and destructive hail which did enormous damage between Wheatley and Waterstock, about six miles east of Oxford. This storm began with a hurricane about 1 P.M., then about 1.15 P.M. hail fell in the form of large lumps of clear ice round a dull centre. It lay to a depth of about three inches on level ground, but was piled by the wind in heaps of two or three feet. The worst of the storm was over by 3 P.M., the depth of rain and melted hail being more than four inches.

June 10, 1886 Eruption of Tarawera (New Zealand).—Though for seven months there had been signs of activity, it was not until early on June 10 that the volcano broke into eruption, and a great cloud of smoke and vapour rose to a height of more than 8 miles and then drifted to the west. This was followed by a downpour of mud, water, and heavy stones that buried the country to a great distance from the volcano and destroyed the well known and uncommon natural feature of the district, the Pink and White Terraces.

June 11, 1928 Waterspouts.—On June 11, about 10.30 A.M. no fewer than five waterspouts were seen between the eastern point of the Isle of Wight and the coast of Hayling Island. They formed near the Nab, and drifted south south west until opposite Bembridge Ledge, where they dissipated.

June 12, 1731 Drought.—The journal of Etienne Azambourg, a farmer of Enfournet, Dept. du Cher, records in June that "There has been so great a drought this year that I do not believe I have seen a similar one, nevertheless the soil was easily worked because the frost had broken the ground, for there had been a long and severe winter which thawed without rain, ... but as it does not rain the corn will soon be lost. There is in France much bringing out of relics and prayers to Saints to obtain from God by their intercession tempests, and among others that of St. Jacques was brought here from Aubigny the 12th of this month." On June 26 he added: "On the 24th it has rained thanks to God as was necessary, this will soon make a harvest."

June 12, 1897 Great Indian Earthquake.—The Assam earthquake was felt over an area of about $1\frac{3}{4}$ million square miles, or half the size of Europe. Buildings were damaged over an area more than twice as large as Great Britain, while, within one almost equal in extent to Yorkshire, scarcely a house escaped ruin. The latter area showed many distortions such as fault scarps (one of which was 12 miles long with a maximum throw of 35 feet), rock fractures, and warping. This earthquake is noteworthy as being the first in which the two series of preliminary waves, primary and secondary, were distinguished on seismograms. For the first time, too, the long waves were observed to pass several stations a second time, having travelled to them through the antipodes of the epicentre.

June 13-15, 1903 Continuous Rain.—There was absolutely unbroken rain in London from 1 P.M. on June 13 to 11.30 P.M. on June 15, a period of $58\frac{1}{2}$ hours. This is the longest period of continuous rainfall on record in the British Isles. The rain was not especially heavy, the total amount being 3.44 in., but there was some minor flooding.

June 14, 1914 Thunderstorm.—A violent thunderstorm broke over south west London during the afternoon, accompanied by violent rain and hail. On Wandsworth Common seven persons were killed by lightning while sheltering under trees. In Richmond Park 3.70 in. of rain fell in $2\frac{1}{4}$ hours, and the neighbourhood of Kingston Station was flooded to a depth of four feet. At Wimbledon the District Railway was submerged by the bursting of a sewer and at Tooting Junction station the water was a foot deep on the platform. At Catford much damage was done by lightning and hail.

Societies and Academies

LONDON

Geological Society, May 14.—**Charles Barrington Brown**: The geology of north eastern British Somaliland. Geological results of four months' field work with the Anglo Italian Boundary Commission in Somaliland. The area discussed is a belt of country along the 49th meridian east, from the coast to about 80 miles inland. There are three structural units: (1) The sunken block or belt of the Aden Gulf bordered on the south by an important fault of 6000 feet throw, from the next unit, (2), the faulted upraised mass of the Al Hills, which continue as a bordering scarp along the south of the Gulf as the Aroru and Afaf Hills; on the south succeeds (3), the inland plateau region at 2000 to 3500 feet elevation. This plateau is entirely unfaulted, but has been subjected to folding of a peculiar kind, resulting in gently undulating areas, unaffected areas, and numbers of small synclinal basins the origin of which is obscure. The Jurassic and Cretaceous

rocks crop out on the face of the Al scarp fronting seawards The Lower Eocene forms all the surface of the Al Hills, a splintered block tilted to the south The Middle Eocene covers all the inland plateau There is a group of faults in échelon in the mountainous country, each with a throw of nil to 2000 feet in a short distance The Aden Rift Fault was traced for a distance of 48 miles

EDINBURGH

Royal Society May 5 —**R Crookall** Some curious fossils from the Downtonian and Lower Old Red Sandstone of Scotland These fossil types occur in association with remains of fishes, *Birkenia*, *Thelodus*, and *Lanarkia* (the first of which occurs in England) They have not so far been recorded from rocks of corresponding age in England Three types are recorded, the first, here named *Taitia catena*, being fairly common, while the remaining two are very rare It is not possible definitely to determine their systematic position Two of the types are probably algal in origin; the affinities of the third are quite uncertain —**A C Stephen** Studies on the Scottish marine fauna additional observations on the fauna of the sandy and muddy areas of the tidal zone The intertidal areas, the head of certain sea lochs on the west coast, and the sandy shores of some of the western isles have been examined The dominant species were the same as on the other parts of the coast Species showed the usual zoning, and these zones occurred in the usual relative order Unless sheltered, the sands on the western isles contain few animals —**E A T Nicol** The feeding mechanism, formation of the tube and physiology of digestion in *Sabella pavonina* The elaborate ciliary mechanism connected with the branchial crown whereby food is procured, consists of catching, sorting, receptive and rejecting tracts Some of the particles pass to the mouth, some are stored in the ventral sacs of the lateral lips to be used in adding to the tube, and the rest rejected via the palps The separation into three groups is dependent entirely upon size The anterior ventral glandular shields and the collar folds are concerned with building the tube An amylase, protease, and lipase have been detected in the digestive fluid and conditions governing their optimum activities determined —**R A Fisher** The distribution of gene ratios for rare mutations Correction and extension of the author's discussion in 1922 of the maintenance of genetic variability in species under the opposing influences of mutations tending to increase the variability and of selection tending to limit it The principal corrections are (i) that the time of relaxation for the decay of the variance in the absence of both mutations and selection is now shown to be $2n$ generations, where n is the number of the species breeding in each generation, (ii) the distribution of gene ratios for the variance maintained by mutations without selective advantage or disadvantage is modified to a form closely similar to that established under the action of selection The former method of differential equations is supplemented by a method using functional equations Exceedingly minute values for the selective advantage or disadvantage are shown to make a great difference both to the chance of success of a mutation and to the contribution of such mutations to the specific variance —**Miss F E Allan** The general form of the orthogonal polynomials for simple series with proofs of their elementary properties ξ_r is the polynomial of degree r in x, defined by the equations $\xi_0=1$, $S(\xi_p \xi_r)=0$ where summation extends over n given equidistant values of the variable x and p has in turn all integral values from 0 to $r-1$ The numerical method of curve fitting by orthogonal polynomials which has been developed by R A Fisher is based on a knowledge of the value of the terminal differences and is given in this paper, and from it have been deduced $S(\xi_r^2)$, the residual variance at any stage, and Tchebitchef's difference formula connecting three successive polynomials of the system By converting the terminal differences to central differences, and building up from these, a general form has been found for the polynomial of degree r of the orthogonal system, from which can be determined the explicit expressions for the polynomials These are given as far as ξ_{10}

PARIS

Academy of Sciences, April 23 —**Ernest Esclangon** The position of the celestial body supposed to be a trans Neptunian planet Four additional negatives were taken on April 15, 17, 19, and 20 the results of the calculations are given and compared with those worked out by Stoyko from observations on Mar 17, 31, and April 17 —**C Sauvageau** and **G Denigès** The sugar of the algæ (Florideæ) Criticism of a paper on the same subject by Colin and Guéguen —**Arnaud Denjoy** A class of analytical functions —**G Maneff** The principle of least action and gravitation —**P Swings** The variations of the relative intensities of the components of the doublets of rotation in the resonance spectrum of sulphur —**C Marie** and **C Haenny** The study of the ammonia oxygen battery The formation of nitrates and nitrites in the presence of alkalis —**Louis Glangeaud** The structure of the coastal regions of Algeria between Ténès and Philippeville —**Loeper, A Mougeot, R Degos,** and **S de Seze** The glycogen of the heart and cardiac medicines As regards glycogen, the drugs examined fall into two groups one class, such as acetylcholine and quinidine, conserve the glycogen, the other, such as adrenaline, tend to make it disappear —**Henri Coupin** The conditions of formation of the conidia and perithecium in *Eurotium repens* —**Raymond-Hamet** The action of hordenine in an animal which has received an intravenous injection of yohimbine chlorhydrate —**Alb J J Vande Velde** and **A Verbelen** Biochemical researches on earth Description of a new method for counting the micro organisms in soil —**A Policard** and **J Devuns** Histochemical researches on the mineral particles contained in the lungs of miners From the histochemical point of view the results obtained from the examination of seven lungs, four showing clinically no pulmonary troubles, confirm the results of MacCrae and of Watkins Pitchford and J Moir on the lungs of Rand miners The authors conclude that under the conditions of work in most coal mines, the distinction between anthracosis and silicosis is purely theoretical

ROME

Royal National Academy of the Lincei, Feb 16 —**Gino Fano** Spacial sections of the Grassmannian variety of straight lines of five dimensional space —**U Cisotti** Dynamic actions of translo circulatory currents round an arched strip —**A Russo** Nuclear dualism and sexuality in *Chryptochilum echini* Maupas The individuals of the two categories of this organism exhibit distinct sexuality, determined by the different quantities of nuclear substance, by the different dividing processes of the nuclei, by their different physiological powers, and by their different destinations The male sexuality, attributed to the *B* gamete, may be an elementary and primitive form of the gametic differentiation of living beings in general, since the micronucleus, having lost all germinative capacity, does not take part in the formation of the micronuclei of the two classes formed after conjugation —**A Tonolo** Intrinsic form of the equations of the equilibrium of elastic media (2) —**Guido Ascoli**

Further regarding the linear representation of continuous functions —**R Caccioppoli** Laplace's series A group of theorems on the convergence of the series developments of Laplace's functions Yn, in particular, two extensions to the spherical functions of Jordan's classical theorem on Fourier's series, are developed —**F Sbrana** The infinitesimal operation in the group of derivations — **G D Mattioli** The determination of the Riemannian varieties assumed by simply transitive groups of movements **M Brelot** The equation, (1) $\Delta u = c(x, y)u(x, y)c_{\sim} o$ — **A Gelfond** The development of entire functions of finite order in Newton's interpolation series —**N Théodoresco** Steps in a theory of the functions of a complex variable in the general sense (2) — **G Vranceanu** The conditions of rigidity of a Vm in an Sn — **E Pistolesi** A rapid method for the calculation of the dynamic effect of a translatory current on a cylinder in the neighbourhood of an indefinite plane wall A rapid method is given for arriving at the result obtained by Raimondi in his recent treatment of this problem - **G Supino** Further considerations on the choice between elastic solutions with equal resultants In a recent note, the conception of fundamental solution was fixed given an elastic solid bounded by the contour σ, this is divided into two zones σ_1 and σ_2, the distribution of forces (or of the displacements) on σ_2 and the resultant and the resultant moment of the forces on σ_1 being supposed given These data do not determine completely the elastic solution, so that the fundamental solution is taken to be that which, while satisfying the data, renders minimum the work of deformation The properties of such fundamental solutions are considered — **B Finzi** Power relative to a translatory circulatory current in which an arched lamina is immersed —**B Caldonazzo** Plane irrotational motions of perfect liquids in the presence of movable obstacles —**U Barbieri** Astronomico geodetic station of Eremo di Cherasco (2) — **A Quilico and M Freri** A new method of formation of pyrrole blacks (2) —**M Airoldi** The age of the andesitic eruptives of the island of Capraia The author s investigations indicate that these rocks belong to the lower Pliocene —**G Lincio** The artinite of Monte Ramazzo (Liguria) — **Giulio Cotronei** and **Aldo Spirito** Zoological constitution and grafting experiments with *Anura* and *Urodeles* - **G Mezzadroli and E Vareton** Action exerted by ultra short electromagnetic waves on the catalasic power of seeds Waves of 2 3 metres length emitted by a radio oscillator exercise a favourable action on the germination of barley and bean seeds, which exhibit increased catalase activity during the first few days of germination —**B Monterosso** Structure and function of the middle intestine of *Peroderma cylindricum* Morphological (and, perhaps, functional) duplicity, which has long been debated, is definitely established in the case of this organism, owing especially to the very marked differential characters which distinguish the forms of one cellular type from those of the other, and also to the clearness with which the initial cell - - the common source of both cycles— is presented

Social Science Teaching *

THE position of the teacher in any field of study becomes constantly more difficult and onerous as the years pass and as the accumulations of knowledge become greater and we hope richer, and as the proper scope and methods of further study and research become daily more intricate and urgent and harder to define or embody in graduate or postgraduate curricula The accumulations of knowledge do indeed increase, but progress is often slow and tortuous and much has to be thrown into the discard under processes of selection more or less ruthless and impartial, for what is sound and apparently unquestionable knowledge to one generation may appear to the next as perfectly untenable Nevertheless, the net result in most directions and during the past half century is steady advance, especially and most remarkably in the physical sciences In the social and moral sciences the acquisition of real and durable knowledge is more difficult to evaluate and sort out from a great mass of questionable matter, hazy hypotheses, and unfounded opinion, but here also there remains, after these necessary deductions, a solid residuum of accumulated fact and sound deduction For the teacher in moral and social philosophy the main difficulties are to discover the solid ground in a country where treacherous swamps and shaking morasses abound, and to guide and stimulate his students to follow the right path and strike out new ones of their own, to strengthen and consolidate existing positions, and establish new ones

The main burden or central core of Prof Wallas's Huxley Memorial Lecture seems to have been precisely this How to stimulate original constructive thought in social science studies, and in particular how best to enable the postgraduate student to make the right use of academic opportunities to enable him, if not to furnish immediately valuable contributions to knowledge, at least to find the right path to that ultimate end But before arriving at this central theme Prof Wallas traverses wide and varied territory and touches lightly on many matters of particular interest and importance At the very outset, however, there may be some dissent from his view that the physical sciences have been the strong, and the moral and social sciences weak, and that this difference between the two branches was well exemplified in the events of 1914–18 Possibly this was not meant to imply that the physical sciences show their

* "Physical and Social Science By Prof Graham Wallas (Imperial College of Science and Technology Huxley Memorial Lecture 1930) Pp 16 (London Macmillan and Co, Ltd, 1930) 1s net

strength predominantly in war and the moral sciences their weakness as a factor in the cause of peace; but on the face of it there seems to be a tendency here to uphold the ancient fallacy that science, especially physical science, has been ever more prone to offer its services to the gods of war than to the embassies of peace. Be this as it may, it is doubtless much more important, in considering the relations and differences between the physical sciences and the social or moral, to investigate thoroughly the remarkable way in which progress in physics and chemistry has profoundly altered those social and economic conditions which it is the purpose of social science to study.

This is the dominant fact of the present age: discovery and invention in physics and allied studies have proceeded at such a remarkable pace that the sociologist and statesman have probably been unable to make the necessary adjustments quickly enough, or have made false adjustments, and have been, generally, very much at sea as to the true fundamental tenets of their own somewhat tottering and unstable social sciences. This uncertainty or weakness, as also the strength of the physical realm, may best be shown in war or under the conditions which lead up to war, but this of course does not mean that the physicist is on the side of the militarist. In any comparison of the social and physical sciences the truest and happiest line to take is that which leads to the view that the dominant and fundamental facts in sociology are to a very large extent physical. It is becoming clearer every day that politics and economics are inseparable, that the former indeed is now mainly concerned with economics, that the older term, political economy, was much truer than the new one; and it is still more clear that the principal data in economics rest on a physical basis. The modern statesman therefore has to take a constantly wider view, more especially of the advances made in physical science and discovery.

Another point of comparison between the physical and the social or moral lies in the remarkable possibilities of introducing experimental methods into the study of the social sciences, an idea which occurred to Bentham and still more emphatically to Mill. Modern economic history is indeed one continuous programme of large-scale experiment, more or less consciously devised, of which Italy to-day is perhaps the most outstanding example, closely followed by many other countries. The conditions and results of these experiments, so far as ascertainable, are being closely studied, for example, by the International Labour Office at Geneva and by the principal universities and schools of economics throughout the world, and the student of the social sciences has, if he searches diligently and fervently, an abundance of material of absorbing interest on which to work and speculate and exercise all his powers of logical reasoning, of induction and deduction, and sufficient also to stimulate and develop all his imaginative and emotional powers, for purely intellectual exercise without these latter—if such cold and isolated working of the mind can in any way be conceived as possible—is quite useless. Prof. Wallas does well to stress this point, and surely when he did so he had the shades of the great Huxley and of the still greater Mill solemnly visible to his mind's eye if not actually visible aloft there in the dim recesses of the ancient lecture hall.

Emotion! To the trained intelligence allied with the sympathetic heart is there not enough, in the present condition of mankind in this his earthly environment, to stir the imagination and the feelings to their highest and deepest? Who of us can look abroad upon the world, upon its present social and economic and political structure and workings, without strange stirrings in our inmost being, without high hopes, deep anxieties, strong faith that right and good will ultimately prevail, and stern determination and indomitable will that they shall prevail. To the most distinguished professor of the highest rank, to the humblest of obscure research students, no work will appear unduly laborious, trifling, uncongenial, or vain when this great end is kept faithfully in view, the end described by Friedrich List as *Pour la patrie et l'humanité*, wherein nationalism brought to its highest and best is ultimately merged in internationalism and the commonwealth of nations.

In the teaching of the social sciences, then, as Prof. Wallas insists, it is necessary to realise fully the force of the emotional in scientific study and research, and we are accordingly faced with the old and universal desideratum in all teaching, an integrated development of all the faculties, both of thought and feeling, although of course thought and feeling, even if separated in name, cannot be separated in act and being. There are many difficulties in realising the ideal under modern conditions, especially for the postgraduate student engaged in more or less original research in the social sciences; and one of these difficulties arises from the scale of modern education and the almost complete impossibility of getting that close and personal contact between professor and student which was so helpful in an older and smaller and

less strenuous academic world Prof Wallas appears to suggest that doctorates should be made somewhat more difficult and involve at least a longer course of study, but the mere lengthening of the course of study by one or more years would not in itself be necessarily desirable or productive of the looked for result In the course of his lecture he introduces, very unobtrusively and lightly, a suggestion that the student should try, at least from time to time, "to turn the flaccid pages of his notebook into something that a news paper critic might regard as decent literature" Here indeed is a practical suggestion that might bear fruit scientific literature generally, from a purely literary point of view, has not maintained that splendid standard set up by Mill, Adam Smith, Huxley, and other giants of a former age The student of social science to day may doubtless find it very difficult to approach that standard, but, equally doubtless, he will find it wonderfully helpful and interesting to try, and he too, more than many, has themes enough—absorbing, thrilling, passionate—to stir him to the attempt

Embryology and Recapitulation

Embryology and Evolution By G R de Beer Pp viii + 116 (Oxford Clarendon Press, London Oxford University Press, 1930) 5s net

THIS little book is from the pen of Mr de Beer, who is one of the more brilliant of the younger Oxford men Its aim is to "dethrone the theory of recapitulation", to persuade us that the development of the individual throws no light on the past history of the race, and that therefore Ascidians need not necessarily be descended from a free swimming vertebrate even though they begin their lives as tadpoles

It is, we believe, the custom amongst brilliant Oxford men to fight for 'lost causes', and surely no cause was ever more hopelessly lost than this, for the doctrine of recapitulation is one of the most securely based inductions of zoology and every year brings additional confirmations of it to light

It is interesting, therefore, to see how Mr de Beer sets about his task Since the history of the race can only be deduced from a study of comparative anatomy, palæontology, or embryology, Mr de Beer must have independent knowledge of what this history was before he can say that embryology does *not* give a true account of it But palæontology is only available in a few cases in which the lineage series is fairly complete, and from the study of these cases it has come about that palæontologists are amongst the strongest supporters of the doctrine of recapitulation Comparative anatomy, so far as it can be legitimately used to give correct information as to phylogeny, is also a strong support of the theory—for comparative anatomy can only take us back a very short way If we strive to penetrate the veil of the past by the comparative anatomy of living adult forms, we soon arrive at a stage where all is wild speculation and fancy But where the type of structure is constant in a well defined group and an abnormal genus occurs within this group, the young stages of that genus have the typical structure of the group, and this is the solid foundation of the recapitulation theory

Mr de Beer's method is to select some embryo or larva and then to point out that it is difficult to imagine that it could have exactly resembled an ancestor But no one, least of all Haeckel himself, who put forward the theory of recapitulation, ever contended that the ancestral record had suffered no secondary modifications Most of Mr de Beer's cases are old and well known ones with which we have fully dealt in our "Textbook of Invertebrate Embryology", in this book the reader will find the causes and nature of these secondary changes fully discussed and we shall not waste the time of readers of NATURE in further elucidating them here But Mr de Beer's reading has been singularly defective for example, he credits Garstang with having been the first to direct attention to the affinity between the echinoderm larva and the larval stages of vertebrates The facts are that the tornaria larva of *Balanoglossus* was mistaken for an echinoderm larva when it was first discovered, and when Bateson, from embryological data, showed the vertebrate affinities of *Balanoglossus*, the connexion between echinoderm and vertebrate phyla was suspected at a period when Prof Garstang was still at school A solid basis for the theory was only afforded when the embryology of *Asterina gibbosa* was worked out in 1896

Mr de Beer lays great stress on a few cases where the palæontological record seems to contradict the evidence of embryology One of these is the structure of the ammonites, for these extinct molluscs carried their life-history around with them written on the inner coils of the shell In some cases these inner coils are ribbed and the outer coils plain, but in the majority of cases the inner coils are plain and the outer ribbed It is argued that, whether evolution proceeded from ribbed to plain or vice versa, one of these records must be wrong But the strong probability is that

both of them are correct For the ribs on an ammonite's shell are not mere ornament They are hollow corrugations which give strength to a shell otherwise too thin to afford adequate support Now thinness or thickness of shell is dependent on the abundance of the supply of calcareous matter if a thin-shelled form wandered into a region where there was plenty of lime its shell would be thickened, and the corrugations would become functionless and disappear, whilst a species with a plain shell would find it necessary to introduce corrugations, if the supply of lime became deficient

A great test of the soundness of a theory is whether or not it can predict results the truth of which will afterwards be independently confirmed Two examples of this may be briefly alluded to here The tympanic bone in mammals was considered on the evidence of the comparative anatomy of recent species to be the equivalent of the quadrate of reptiles, which is frequently curved round the auditory opening The embryological evidence suggested that the quadrate of reptiles had been changed into the incus bone of the mammalian ear Now from Africa a series of skulls have been discovered showing every stage in the transition from quadrate to incus Again, the palæontological evidence makes it clear that the five fingered hand of the land vertebrate must have been derived from the fin of the Devonian crossopterygian fish Steiner, working on the embryology of the wing of the bird, arrived at the conclusion that the fourth finger represented the axis of the fin and that three rays on the preaxial side corresponded to the thumb and first two fingers, whilst the little finger represented a single postaxial ray The same conclusion was independently arrived at by palæontologists studying the fins of the latest crossopterygian fish and the hands of the earliest land animals

Mr de Beer commits an amusing error when he says that the symmetrical stage in the development of the hermit crab does not represent its adult ancestor but the *larva* of the crab from which it is derived. There is no close affinity between so called 'hermit' crabs and true crabs, and the former are related to the Galatheidæ, which when adult have well-developed symmetrical abdomens like those of the young hermit crab

It might be asked what motive induced Mr de Beer to embark on this errand of hopeless knight-errantry We are not left in doubt as to the cause It is an attempt to support the gene-mutation theory of evolution, which is totally irreconcilable with the recapitulation theory, a fact which Morgan himself has recognised Now supporters of the recapitulation theory freely admit that mutations constitute an important set of biological phenomena they know that when mutations are crossed with the type segregation occurs, and it is clear that the study of these abnormalities is of great importance to all interested in cultivated plants and domestic animals They doubt very much if any additional light is thrown on the nature of mutations by inventing imaginary causes called genes to account for them but they are perfectly certain that genes are not units out of which the hereditary powers of an animal are built up that, on the contrary, genes represent the effects of external damage to these powers, as the experiments of Miller have clearly proved, and that therefore genes have played no part in evolution A prominent geneticist said, in discussing the results of Miller's experiments, "The mutation theory of evolution is dead"

Mr de Beer's original contribution to the discussion of embryology is to employ the terms 'pædomorphosis' and 'gerontomorphosis' for two supposed types of evolution By the latter, he means changes occurring relatively late in life-history which result in an improvement in an existing organ by the former, changes suddenly occurring in the earlier stages by which the whole trend of evolutionary history is altered and a new phylum springs into being

We shall briefly sketch the origin of the Gastropoda according to the recapitulatory theory and to pædomorphosis and appeal to readers of NATURE to decide between them According to the first theory the original mollusc was a bilaterally symmetrical animal which glided over the mud by means of its ventral cilia and was able to keep its body on an even keel But when it took to crawling over hard ground its humped back, which was protected by the shell, gradually sagged to one side and this caused one side to be stretched and the other to be crushed the stretched side grew more quickly than the crushed side, and thus was initiated that inequality of growth which not only gave rise to the spiral shell of the gastropod but also twisted the anus round to the front of the neck This change, which must have taken ages to produce, was already complete in the Cambrian 400,000,000 years ago—it was a change in adult habits and structure, but it is now pushed back by tachygenesis until it occurs during the free-swimming stage of the larva

According to pædomorphosis, the gastropod owes its origin to the occurrence of a sudden and miraculous 'mutation' in the larva by which at one fell swoop it twisted its visceral hump and shell through

an angle of 180 degrees By this fortunate miracle it now became able to protect its ciliated band or velum by withdrawing it within the shell, which it previously was unable to do, and so it survived whilst all its neighbours perished (Incidentally we may remark that the Lamellibranch veliger, which has its anus and mantle cavity behind, is nevertheless able to withdraw the velum within the shell)

The mutation theory of evolution—or evolution by sudden jumps—was first put forward by Bateson in 1894 When Haeckel attended the International Congress of Zoology held at Cambridge in 1898 this theory was discussed and Haeckel's pregnant criticism was, If this sort of theory is to be put forward for acceptance it would be better to return to Moses at once" E W MACBRIDE

Universities of the British Empire

The Yearbook of the Universities of the Empire, 1930 Edited by Sir H Frank Heath Published for the Universities Bureau of the British Empire Pp xv + 840 (London G Bell and Sons, Ltd, 1930) 15s net

THIS super calendar of the seventy universities of the British Empire is packed with every kind of information about them likely to interest the learned world, government departments, clubs, and the public generally Who's where in those universities is here ascertainable with a minimum of trouble likewise who's who so far as concerns appointments and degrees held by professors and other university teachers and the university by which each degree was granted The personnel of each university is exhibited in such a way as to show at a glance the strength of the staff employed in each field of learning Following this directory is a summary account of the equipment of libraries, museums, laboratories, etc, of the university, the degrees, diplomas, and certificates which it confers, its composition fees, scholarships open to graduates, residential accommodation, extra mural work, publications, and, finally, a summary of events of outstanding interest which occurred during the past academic year, with statistics of the numbers of students in attendance and degrees conferred Brief notes concerning the university's origin, the salient facts of its history and its constitution, are prefixed to this summary in many cases, but in others particulars of the university's early history, which appeared in last year's issue, have been replaced by a note—" For early history see the Year book for 1929" In chapters introductory to the sections dealing with the universities of Great Britain and Ireland, of Canada, of Australia, of South Africa, and of India, respectively, their common history, regulations, and practice are summarised

Appended to these sections are accounts of the conditions governing admission to various professions and careers for which university studies are a fitting preparation, matriculation examinations and admission of students from abroad into the universities in the British Isles, lists of post graduate scholarships, etc, and lists of centres of scientific research and of scientific information, whether connected with universities or not, to which independent research workers are admitted

A noteworthy feature of the present issue is the skilful marshalling of the information collected concerning the facilities available in the British Empire for scientific research in all its principal branches, and the aids available in every country for post graduate students and research workers of British citizenship irrespective of the place of their education those open only to graduates of particular universities being particularised in the appropriate sections of the main part of the book Such a comprehensive survey, which Sir Frank Heath, with his experience of work in the Department of Scientific and Industrial Research, was peculiarly well fitted to undertake, has not hitherto been published and was overdue

The 'Yearbook' lacks tables of comparative statistics So far as Great Britain is concerned, the inclusion of such tables would, it is true, have involved a duplication, though not necessarily a wasteful duplication, of a service already undertaken by the University Grants Committee As regards the other parts of the Empire, the absence of comparative statistics is to some extent justified by considerations set forth on page 6 of the introductory chapter on the universities of Great Britain and Ireland, wherein an estimate of the number of full time students (48,600) is qualified by the remark that the figures do not include the students of the institutions other than universities and university colleges in which professional education of university grade is given in theology, teaching, agriculture, etc, nor students reading privately for the external degrees of the University of London (this makes the more noticeable the absence of statistics of those degrees), for the bar, etc "This makes comparison with statistics of other countries difficult, as does also the fact that the work of the higher forms of many of our secondary and 'public' schools corresponds with the earlier stages of the work done in colleges and

collegiate departments of some foreign universities, e g in America " Despite these drawbacks, the following table summing up certain of the statistics given in the Yearbook " is not without interest The figures for the French Canadian universities appear to include a large proportion of students engaged in work of pre matriculation standard, and their degrees (baccalauréat) do not correspond to any of the English degrees

	Full time* Students	First Degrees
Canada		
Toronto	6 422	839
McGill	3 191	343
4 western provincial universities	6 804	766
3 French universities	9 774	407
12 other universities	6 457	795
Canada totals	32 648	3 150
Australian universities (6)	6 390	1 031
New Zealand	1 868	400
South African universities (4)	5 830	902
Indian universities (17)		13 248
819 American universities and colleges excluding pre matriculation departments and 155 603 law medical dental theological pharmacy and engineering students	Enrolled students in 1925-26 both full time and other 611 660	

Close co operation between the parts of the British Empire is an ideal which innumerable public speakers and writers constantly proclaim What more promising field for such co operation could be found than the learned world and what more indispensable documentary aid to co operation in this field than the Universities Yearbook ? Yet we are told in the preface that the sales are so comparatively small that the annual deficit incurred in respect of it has been very heavy and the Universities Bureau has, in consequence, been constrained to raise its price from 7*s* 6*d* to 15*s* The new price cannot be called excessive when compared for example with the price of Minerva , but one regrets that the increase should have been necessitated by the inadequacy of the Bureau s income

* The number of *part time* students is not given in all cases In universities in Canada Australia New Zealand and South Africa for which their number is given there were 11 359 as compared with 29 791 full time

A Logical Course of Elementary Physics

Physics By W J R Calvert (General Science Series) Part 2 *Sound* Pp vii + 142 3*s* Part 3 *Light* Pp vii + 202 3*s* Part 4 *Magnetism and Electricity* Pp x + 333 4*s* (London John Murray, 1929)

THESE three books are worthy successors of the author s mechanics and heat—the first of the series—which was published in 1924 Mr Calvert is well known as a teacher of teachers, and no one who instructs the young in the elements of physics can afford to ignore these volumes, whatever conclusion he may reach as to the desirability for their use by his pupils

Obviously the outcome of long and thoughtful experience, the books are, in a sense, too good, for they read almost as if they were taken down by a stenographer as the lectures were delivered and it is to be doubted if text books should read like the spoken word The movement is sometimes too slow too logical and perhaps too laboured Yet this is not always so for on the twentieth page of the volume on light we find Our present views have returned somewhat to the Newtonian view, except that in the place of corpuscles we have quanta of energy associated with the idea of a periodic electro magnetic disturbance There after that volume trips more lightly and the going is made easier by the relegation of lens formulæ and details about practical work to appendices at the end of the book

The design of the author has been to give a physical basis to the subject and his treatment throughout the series has been as devoid of mathematics as is reasonably possible In this he has been very successful in the volume on sound which, being full of interesting practical applications, holds the attention of the reader The chapters on reflection here are very good

In some respects, the book on magnetism and electricity is the most interesting of all Many, perhaps most, teachers prefer to start from some point within the pupils ken batteries ammeters, electric bells, and the like Not so the author, who only allows his readers to reach these things after a logical and lengthy journey Whether they will have acquired a thirst for more knowledge by that time may be doubted, but there is no doubt at all about the skill with which the route has been mapped out Those who insist on the logical development of ideas for the young will find it to perfection here Starting with only just sufficient magnetism for his purpose the author deals immediately with current measurement, and then by an easy transition passes to electrostatics, where he wisely avoids the usual system of units Then follows—too soon, as some will think—a chapter on the structure of the atom, after which potential measurement is introduced by the heating effect of current, when at length the way to Ohm's law is opened up, and all is plain sailing again

If the author has chosen a hard route, he has at least made it as easy as possible by avoiding un

necessary difficulties, as for example the measurement of magnetic moments and the use of the tangent galvanometer, which can be found by the morbidly curious in appendices at the end of the volume An excellent chapter on rays adds to the interest of the book, and there is an admirable preface, which provides food for the teacher, if not for the taught

Miers' Mineralogy

Mineralogy an Introduction to the Scientific Study of Minerals By Sir Henry A Miers Second edition, revised by Dr H L Bowman Pp xx+658 (London Macmillan and Co, Ltd, 1929) 30s net

THE first edition of this book appeared in 1902 It was clearly written, admirably illustrated by drawings and photographs, and it soon became a standard text book on the subject of pure mineralogy The editor of the second edition, who is also Sir Henry Miers's successor in the chair of mineralogy in Oxford, has added to the illustrations, brought the text up to date where necessary, adding a new chapter on the investigation of crystal structure by means of X rays, but has retained the original text so far as possible

In the main, this plan has been successfully carried out, and it is perhaps only in the 'Introduction' that there has been a too strict adherence to the original In the body of the text full justice is done to the recent advances in the study of crystal structure, but in the 'Introduction' it is barely mentioned, with the result that some passages, which in the first edition were remarkable forecasts of possible developments, are now almost out-of date, so nearly have their prophecies been fulfilled

The additions to the text, including 63 new figures, amount to 74 pages, of which 22 are devoted to the new chapter on crystal structure, and further pages in the descriptive part of the book give explanations of the structure of diamond and graphite, blende and wurtzite, α- and β quartz

It is not to be supposed that the relatively small additions to the text indicate either lack of progress in mineralogy or want of thoroughness on the part of the editor Much that has been done for the advancement of mineralogy within the last twenty-eight years lies outside the scope of the book, which was clearly limited by the author to the 'essential' properties of minerals and the means by which they are investigated In the description of the 'essential' properties of minerals, apart from the determinations of crystal structure, there is little new matter which can find a place in a text book The generally accepted system of classification has remained unaltered and work on systematic mineralogy has been devoted to the perfection of measurements and chemical analyses, and to the description of new minerals most of which are too rare to be included in a book intended for students In the improvement of methods by which the properties of minerals are investigated there is much that is new that might have been introduced had space permitted There are, however, many good text books to which students can be referred for recent developments in petrographic methods, in the use of the 'universal' stage of Fedorov, and in the study of polished plates of opaque ores, and by deciding to omit descriptions of these methods the editor has left us with a text book which is not only reasonable in size but also eminently readable

The printing of text and figures has been admirably done, and the price is not excessive for a book of this size

Our Bookshelf

Ions, Electrons and Ionizing Radiations By Prof James Arnold Crowther Fifth edition Pp xii+353 (London Edward Arnold and Co, 1929) 12s 6d net

THE appearance of a fifth edition of Prof J A Crowther's well known book, which gives in a simple form a comprehensive and systematic treatment of an important range of experimental physics and its interpretation, has been necessitated by the progress of research during the past five years The author's object has been to preserve the point of view of the book in relation to scientific thought, and the alterations effected are of a minor character, among the most important additional sections are those dealing with Aston's work on the packing effect, the Compton effect and theory of X-ray scattering, the work of Davisson and Germer and of Thomson on the diffraction of electrons by a crystal, Millikan's discovery of cosmic radiation, and the magneton together with the experiments of Gerlach and Stern New and improved photographs by Wilson of the tracks of ionising radiations replace the earlier ones The alterations have resulted in an enlargement of the book to the extent of about 24 pages

As pointed out by the author, the task of selection from new and old material has not been easy In a work of this type the quantum theory must necessarily play a prominent part in an interpretation of the experimental basis of physics, the section on the quantum theory is, however, unchanged, and a reader otherwise unaware of the present position would scarcely suspect the epoch making changes through which this matter has been passing A few lines only are devoted to the

new wave theory of the electron in connexion with the work on electron diffraction mentioned above Sections dealing with the magneton and the electron theory of conduction include no mention of the spinning electron and Sommerfeld's work on the theory of conduction with the help of the Fermi-Dirac statistics

Though the author has deemed it advisable to refrain from introducing matter which is at present somewhat speculative, the more advanced reader will be pardoned a feeling of regret that the results of some of the immense ranges of recent research have not found a place in the new edition

N M BLIGH

Artists in String String Figures, their Regional Distribution and Social Significance By Kathleen Haddon (Mrs O H T Rishbeth) Pp x + 174 (London Methuen and Co, Ltd, 1930) 6s net

MRS RISHBETH has long been known as a zealous collector and student of the string games known popularly as 'cat's cradle' In this volume she justifies a study which, to the Philistine, may seem puerile, by indicating its bearing upon the problems of cultural anthropology, showing on one side that these string games, especially in their more complicated forms, represent an expression of a creative or artistic impulse, and, on the other, give the student certain quite specific pieces of information about the environment and social facts in the life of the people among whom they are found The games are here described according to their geographical distribution, five games being taken from each group

Although more than eight hundred games are known, there are many and striking gaps in our knowledge Yet when due allowance is made for this, the first remarkable fact to emerge is the peculiar geographical distribution of the games While the string figure is widely distributed, occurring in North America, probably South America, though the Guianas at present furnish the only record, Africa (at present sparsely), Australia and Oceania, yet Eurasia is practically a blank space The author, therefore, concludes that while the Eskimo, redskins, tropical browns and blacks, have these figures, the white, yellow, and Asiatic brown people have practically none

The subjects also are curiously distributed, or perhaps more correctly show curious absences In West Africa, for example, no figures represent big game Mrs Rishbeth suggests that these absences may conceal interesting evidence as to native ways of thought, and in any case call for further investigation Mrs Rishbeth's suggestive treatment of her fascinating subject cannot fail to stimulate further collection which may bring the information desired

An Inorganic Chemistry By Prof H G Denham Second edition Pp viii + 688 (London Edward Arnold and Co, 1930) 12s 6d net

PROF DENHAM gives a lucid and logical exposition of his subject within a moderate compass He bases his arrangement upon the periodic system, and introduces new laws or generalisations as the occasions arise In this way he secures a continuity of narrative which is sometimes lacking in works dealing with this subject His method of presentation has the further merit of effecting a smooth correlation of the purely descriptive side of inorganic chemistry with some of the leading conceptions of physical chemistry Objection may be raised to certain details, such as the designation of phenol as an aromatic alcohol (p 377) and the statement (p 363) that "nearly three hundred hydrocarbons have been isolated" On the whole, however, the book appears to contain very few factual misstatements We suggest that more information respecting the localities in which important minerals are found might be included with advantage in a future edition Altogether, this is a carefully planned book, which may be recommended for the use of advanced classes in the schools and intermediate classes in the universities It is well printed, adequately illustrated, and easy to read

Growing Up How one did it in Different Times and Places By Ellen C Oakden and Mary Sturt Pp 238 (London Kegan Paul and Co, Ltd, 1930) 5s net

THIS book embodies an excellent idea, and the idea is very competently carried out It is meant for boys and girls, but we should not envy the adult who failed to find it interesting The book tells what sort of lives boys and girls lived, and especially how they were educated, in other times and in other lands—in ancient Greece, in the Middle Ages, and the age of chivalry, in Shakespeare's time, a century ago, and fifty years ago It tells how ladies were made in times gone by, and what sort of life a boy lived in the pioneer days of western America The fare is varied, but not incongruously so

One point strikes us forcibly Our forbears never learnt the elements of scientific method in school laboratories But some of them, as this book reminds us, managed to acquire a keen and a life long interest in the wonders of earth and sea and sky The old fashioned naturalist, who loved Nature, but set small store by analysing and dissecting her, knew something of the joy of living, which is less common since we began to teach science in our schools So perhaps even now we have not hit upon the very best way of 'growing up'

The Living Past By John C Merriam Pp xii + 144 + 16 plates (New York and London Charles Scribner's Sons, 1930) 7s 6d net

THE author of this little book has obviously pondered deeply on the facts revealed by geological science He tells us that the seven chapters are "episodes selected because of their touch with especially significant aspects of the problem of life history", and the subjects he has chosen are mainly drawn from the magnificent sections of the Grand Canyon of the Colorado On his themes the author has written lightly with singular grace and charm, and the absence of technical details will add to the pleasure of the general reader The book is well illustrated, but the price seems too high

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Crystal Structure of Krypton

WE have made two Debye-Scherrer exposures of solid krypton at the temperature of liquid hydrogen boiling under normal pressure, one with copper K_α radiation, the other one with unfiltered iron radiation. As was to be expected, we found a face-centred cubic lattice. The lattice constant is 5·59 A. The calculated density is 3·13. The distance of the centres of neighbouring krypton atoms amounts to 3·96 A., whereas from viscosity measurements the value 3·23 A. is deduced for the diameter of the atoms. Ratio 1·22; the analogous ratios for neon, argon, and xenon are 1·35, 1·29, and 1·23 respectively.

We are indebted to G. Claude for the quantity of krypton we used.

A more detailed account of this work is being published in the *Proceedings of the Amsterdam Academy*.

W. H. KEESOM.
H. H. MOOY.

Leyden, May 31.

IN a previous letter to NATURE upon the crystal structure of xenon, we announced that we would next examine krypton. We have modified the camera used for the previous experiments by reducing to a great extent its internal volume and making it perfectly gas-tight, so as to be able to work in a krypton atmosphere, thus overcoming the difficulties previously encountered.

The gas has been brought to the solid state upon a quartz capillary (set in the axis of the Debye camera) internally cooled by liquid nitrogen. The photograms obtained, with iron anticathode, showed 14 lines, 4 of which belong to the K_β radiation, corresponding to a face-centred cubic structure. The lattice constant of the elementary cell of krypton, containing 4 atoms, is $a = 5·78$ A. The following data have also been calculated: volume, 193×10^{-24} c.c.; density, 2·83 gm./c.c.; atomic radius, 2·04 A. Experimental details and a discussion upon the present data will be published elsewhere.

Ethyl Alcohol: a Product of High Pressure Syntheses

DURING a recent discussion at the Royal Society on catalytic reactions at high pressures, Mr. M. P. Applebey, of the Imperial Chemical Industries, Limited, Billingham, remarked that "in our experience we have never succeeded in obtaining with any catalyst whatsoever, more than a mere trace of ethyl alcohol".

This statement, which expresses a matter of fact, has since been followed by allusions in the Press which appear to suggest that there is some fundamental reason why this alcohol, unlike other primary alcohols, may not be produced in the series of condensations occurring between carbon monoxide and hydrogen in presence of various catalysts.

Dr. E. K. Rideal, writing in NATURE of April 12, p. 584, refers to the production through the foregoing condensations of a whole sequence of higher aldehydes and alcohols, "with the possible exception of ethyl alcohol."

A paraphrase of this statement appears in a leading article of *Chemistry and Industry*, April 25, 1930.

On the other hand, there is the testimony of Franz Fischer and Hans Tropsch ("Brennstoff-Chemie", **4**, 281; 1923), who found that in the presence of alkalised iron under pressure, ethyl alcohol was present among the condensation products of carbon monoxide and hydrogen. Moreover, in a lecture to the German Chemical Society (*Ber.*, **59**, 30; 1926), A. Mittasch included ethyl alcohol in a comprehensive list of the organic products of this condensation. It should, however, be recognised that these German memoirs indicate conditions such as favour the production of very complex mixtures, including alcohols, ketones, aldehydes, organic acids, esters, and hydrocarbons.

Working with various catalysts we have obtained evidence of the formation of ethyl alcohol in not inconsiderable quantities. Our specimens of alcohol boil at 78·2°/760 mm. and furnish ethyl 3 : 5-dinitrobenzoate melting at 92° and giving the same melting point when mixed with a 3 : 5-dinitrobenzoate prepared from an authentic specimen of ethyl alcohol.

It would accordingly be desirable to suspend judgment on this debated point until the appearance of more complete evidence. We propose to publish in the near future a detailed account of our production of ethyl alcohol from carbon monoxide and hydrogen.

The Acquired Characters of *Alytes*

I AM glad that Prof. MacBride (NATURE, May 3) agrees that a reversion to the original environment would be likely to produce the result I suggest; but I am sorry he assumes that I accept Kammerer's work in the sense he does. What I said was, that even if all Kammerer's results with regard to *Alytes* were accepted, the experiment could not be held as complete until the effects of a reversion to the original environment had been demonstrated. Prof. MacBride now says that, unless there existed in the germ plasm potentialities to respond in a definite manner to changes in the environment, there would be no possibility of evolution.

I entirely fail to see any reason for this assertion. Such potentialities are doubtless of great value to the individual, but what is their relation to evolution? That such potentialities have been produced and may be modified in the course of evolution like other characters, most biologists would, I imagine, be prepared to admit; but it seems reasonable to regard them as the product rather than as the cause. Let me state a hypothetical case. An animal during its development passes through a stage where it possesses gills. It has the potentiality to respond to the environment so that if the parents are kept from water the gill stage occurs in the egg, but if the parents are given free access to water, the animal hatches out earlier and the gill stage occurs in the free swimming individual. I do not see, however often the change of environment may be made during consecutive generations, with its consequent temporary change in the character, that any new character or permanent

change in an existing character need be assumed For such a permanent change, a modification in the potentialities must occur

Prof MacBride apparently believes that such a modification is produced by the action of the environment upon the potentialities This explains his assertion that evolution would be impossible without potentialities in the germ plasm to respond in a definite manner to the action of the environment He is assuming the truth of *his* view of a disputed point The opposite view is that such modifications are produced in successive generations by the survival of those variations which occur in animals on the production of a new individual The case of Kammerer's *Alytes* does not seem to me to be convincing, even as stated by Prof MacBride

Since writing the above, I have seen Prof Przibram's letter in NATURE of June 7, p 856

Even if the statement be accepted that *Alytes* continues to lay its eggs in water after the temperature has been reduced, the original environment has not been restored, if it had, there would not be sufficient water for it to lay its eggs in A true 'return' to former conditions, then, necessitates the absence of water In saying that deprivation of water would not be such a 'return' but "induction in the opposite direction", Prof Przibram appears to me to be making an assumption necessary only if the facts are to be forced to fit in with a preconceived idea He has for the moment forgotten that von Nägeli's experiments have been carried a step further in the United States, and that the plants show various stages of modification in the characters they develop, corresponding to the variations in the environment Given the same modification of environment, the same modification of character appears, whether extreme or intermediate I see no more suggestion of the inheritance of acquirements in the case of *Alytes* than in the case of the plants

If Prof Przibram will extend his admission that the development of the nuptial pad depends upon 'external conditions' to the laying and hatching out of the eggs of *Alytes*, I cannot see why he should quarrel with any statement in my letter of April 12 As I said then, Kammerer's experiments with *Alytes* are not complete as they stand

An Exceptional Whirlwind in Natal

AT the village of Impendhle, Natal, on Mar 23, 1930, there occurred a whirlwind of considerable violence, and the damage resulting therefrom illustrates in a remarkable manner the great intensity of the rotatory and suctional forces that can be engendered The course travelled by the whirlwind could be followed, as a cloud was caught up in its vortex (Fig 1)

I am indebted to Mr E T A Minkner for the following notes and for the accompanying photographs

On the morning in question the wind came from the north, and during the whirlwind it changed to the west There was a little hail, but not much rain A peculiar, horizontal cloud was first noticed to the west of the village near the Impendhle Mountain The cloud moved in a northerly direction, and when above a certain hill known as the 'W' it became funnel shaped The funnel travelled in a circular course to the north and round to the east of the village Afterwards it became longer and thinner until it disappeared in the general canopy of cloud The photograph was taken at 1 45 P M, when the funnel-shaped cloud was almost in contact with the ground

The line of travel of the apex of the whirlwind over

FIG 1 —Cloud caught up by whirlwind Impendhle, Natal, 1 45 P M, Mar 23 (Photograph by Mr E T A Minkner)

the ground was marked by devastation The rotatory force rooted up grass and played havoc with a group

FIG 2 —Trunk of wattle tree twisted and shattered by whirlwind of Mar 23 at Impendhle, Natal. (Photograph by Mr. E T A Minkner)

of black wattle trees One tree about 3½ feet in circumference was bodily twisted off its roots and drawn up about 90 feet in the air, while another

larger tree had its solid trunk split and twisted in the manner shown in the second photograph (Fig 2)

The top of the tree and most of the lateral branches were broken off, and doubtless the leverage exercised by the action of the rotating wind on the boughs assisted materially in the twisting and shattering of the trunk, since it is almost inconceivable that the force exerted would be so excessive as to twist a tree trunk by direct action on the trunk itself

The great suctional force was demonstrated by the tree which was drawn up into the air It is clear that, if the whirlwind had happened to pass over a body of water containing fishes, a rain of fishes would have resulted In this connexion it may be mentioned that on April 14, 1909, an authentic case of the fall of fresh water fishes occurred at Newcastle, Natal

The Oogenesis of *Lumbricus*

THE current number of the *Quarterly Journal of Microscopical Science* contains an interesting paper by Dr Vishwa Nath on the vexed question of the oogenesis of the earthworm (*Pheretima*, in his case)

After having gone over the earthworm oogenesis again, we agree with practically everything Dr Nath has written However, we have found a 'vacuolar system' as well Dr Nath states that "Vital dyes, namely, neutral red and janus green *B*, have been extensively used [by him] in the form of very thin watery solutions, but they do not in any way improve the appearance of the egg " Dr Nath, Mr Harvey, and the senior writer have previously overlooked the 'vacuolar system', but if the ovary is left for *about an hour* in neutral red Ringer (pink solution) a fine system of red globules stains up We have no doubt that if Dr Nath tries longer periods he will also find these globules

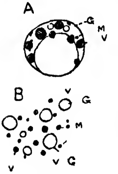

FIG 1

Now there can be no doubt that there is a real vacuolar system in mammals, molluscs, and insects, for in certain cases it can be seen without staining, or in directly fixed tissues (Kolatschew) But these globules in the germ cells of earthworms take a much longer time to stain (or appear) In cœlomic epithelial cells (Fig 1, A), however, they appear quickly, and certainly resemble the 'vacuome' of molluscs We could not satisfy ourselves that the globules were present in *Lumbricus* cells, *intra vitam*, without staining, or after osmic acid It does not seem possible entirely to dismiss the idea that these globules might be segregation vacuoles and not pre existing structures Possibly many neutral red staining globules are segregation vacuoles and have been confused with the neutral red vacuoles of such animals as *Abraxas* and *Cavia*, where there is, before staining, a definite pre-existing aggregation of globules We have also succeeded in staining a 'vacuome' in nerve cells of *Lumbricus*

One point we should like to stress These vacuoles filled with neutral red dye are not related in any way to the argentophile and osmiophile bodies, which can be seen *intra vitam* in the earthworm ovary and nerve cord, and are known as Golgi elements The mitochondria, the neutral red globules, and the Golgi elements can be seen side by side separately (Fig 1, B)

Fechner's Law

THE power of the eye to distinguish differences in brightness has hitherto been specified by the ratio $\Delta I/I$, where ΔI is the least perceptible increment in brightness when the eye is observing a surface of brightness I Weber stated that the ratio was constant, and this statement has been known as Weber's law or Fechner's law It was obvious to Fechner that the law did not hold for high and low intensities But he considered that these deviations were due to disturbing factors dazzle at high intensities, and the intrinsic light of the eye at low intensities

In a recent paper (*Phil Mag*, 8, p 520, 1929) R A Houstoun suggested that the reciprocal of Weber's ratio was a Gaussian probability curve when

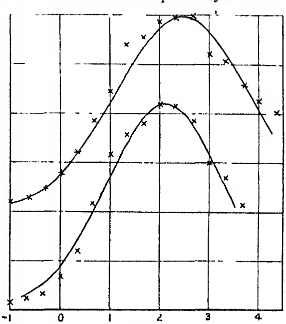

FIG 1

plotted as a function of the logarithm of the intensity We have tested this point, and a full description of the experiments will be published in due course, but we think it desirable to state here, in view of the number of physiologists and psychologists interested in the matter, that $I/\Delta I$ forms a good probability curve The accompanying diagram (Fig 1) shows typical sets of observations for red light, the abscissæ giving logarithms of the intensity and the ordinates $I/\Delta I$ In the interests of clearness, the zero of the one curve has been displaced vertically upwards The curves are probability curves fitted to the results The observations for blue light agree with those for red except at low intensities, where there is a deviation if the eye is dark adapted

It may be shown that the sensation at any intensity is proportional to the area to the left of that intensity, and that the obvious interpretation of the observations

is that we are dealing with a group of percipient elements, forming a homogeneous population, which come over the threshold as the intensity is raised

Presence of a Yeast in the Death Watch Beetle (*Xestobium rufo-villosum* De G.).

IN a letter on the above subject in NATURE of April 26, p. 635, Mr. L. N. Staniland directs attention to the presence of yeast symbionts in *Xestobium* in connexion with the work of our colleague, Mr. W. G. Campbell, on the chemical aspects of the destruction of oak wood by powder post and death watch beetles, *Lyctus* spp. and *Xestobium* sp. (*Biochem. Jour.*, 23, No. 6, pp. 1290-1293; 1929).

A study of symbiosis in relation to certain wood boring beetles has been started by this laboratory in order to check and add to the results of the earlier workers Karawiew, Escherich and Buchner, and of the more recent investigators, Heitz and Breitsprecher. The work of the last named (*Zeitschr. f. Morphol. u. Ökol. der Tiere*, 2, parts 3 and 4, pp. 495 *et seq.*; 1928) is the most important in connexion with the Anobiidæ, with which family we are chiefly concerned.

So far, most of Breitsprecher's observations on the larvæ of *Xestobium* and *Anobium* have been confirmed. This worker could find no evidence of the presence of yeast organs in the ovipositor of dry museum specimens of *Ptilinus pectinicornis* L., but our sections of the larvæ have disclosed the presence of a pair of yeast filled organs lying anterior to the mesenteron and connected with it by means of very fine ducts. The larva of this beetle seems therefore to be more specialised in its symbiotic adaptations than that of *Anobium punctatum* De G., which in the opinion of Breitsprecher is the most highly developed in this respect of the Anobiids which he has examined.

We have succeeded in isolating pure cultures of yeasts from *Anobium* and *Xestobium*, but whether these yeasts correspond to the actual symbionts remains to be proved. It is hoped that some light may be thrown on the chemical aspect of the metabolism of these insects if the yeasts can be grown on cellulose media.

A histological study of the adult beetles has just been started. Meanwhile, our dissections of *Xestobium* females in conjunction with Breitsprecher's section work lead us to disagree with Mr. Staniland's use of the term 'spermathecae'. The organs to which he refers are, in our opinion, specially developed structures; the spermatheca with its associated gland is quite distinct and occupies a normal position for most Coleoptera, that is, just anterior to the bursa copulatrix.

Raman Effect in Metallic Halides.

IT is known that the crystalline halides of the alkali metals (for example, rock salt) fail to exhibit the Raman effect. With the view of elucidating the reason for this behaviour, I was led to examine a series of other crystalline metallic halides, using the technique described in a recent note (NATURE, Mar. 22, p. 463). Amongst the numerous solids examined, the two chlorides of mercury stand out conspicuously, giving Raman lines of great intensity corresponding to both positive and negative shifts of frequency (Figs. 1 (*a*) and (*b*), lines marked with arrow, the exciting line being 4358 A.).

When we compare the highly contrasted behaviours of the chlorides of mercury and of the alkaline halides, and remark that mercurous chloride is insoluble in water, and that mercuric chloride in solution is a poor conductor of electricity, the inference is suggested that the electrovalent type of chemical union between atoms is unfavourable, while on the other hand the covalent type of linkage is highly favourable, for the production of the Raman effect. This

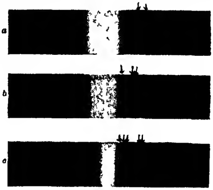

FIG. 1.—Raman spectra of (*a*) mercuric chloride (*b*) mercurous chloride and (*c*) sulphur.

inference is supported by all the evidence obtained by me. It is found that lithium, barium, and thorium chlorides give no observable effect. On the other hand, the solid trichlorides of antimony and bismuth give strong Raman lines, while auric chloride, cadmium iodide, and anhydrous zinc chloride give just detectable lines of feeble intensity. The contrasted behaviour of stannous and stannic chlorides is also an example worthy of special mention. The former gives no new lines, while the latter is a liquid which gives an extremely strong Raman spectrum.

Fig. 1 (*c*) is the Raman spectrum of ordinary rhombic sulphur with the green line of the mercury arc as the exciting radiation. It is of interest as showing that the Raman effect may be successfully photographed even with strongly coloured solids.

Raman Effect of Sulphuric Acid.

USING incident mercury light, the Raman effect of sulphuric acid at varying concentrations has been studied. In the results below, 100 per cent is the purest acid obtainable; 50 per cent is 1 molecule of sulphuric acid to 1 molecule of water; 0 per cent is pure water.

At 100 per cent, Raman lines were obtained at 4585 A., 4566, 4542, 4470, 4438, 4276, 4252, 4224, 4203, 4171, 4142. These decreased in number and intensity at 90, 80, 70, and 60 per cent, until at 50 per cent the lines found were 4566 A., 4542, 4470, 4438, 4224, 4203. At 40 per cent, Raman lines were found at 4566 A., 4547, 4474, 4441, 4224, 4203. At 30 per cent no lines were found, but weak bands were present, which were probably due to the water, for they increased in number and intensity at 20, 10, and 0 per cent.

Forty-five per cent concentration gave the same results as 50, and 35 the same as 30. The sudden change between 45 per cent and 35 may indicate that

a large number of molecules are broken up into ions between those points Some of the lines found at 40 per cent may be due to sulphate ions. Most of the lines in pure sulphuric acid were easily obtained in a three minute exposure and the strongest appeared in a one minute exposure For other concentrations fifteen minutes was sufficient

The Swimming of Cuttlefish

IT may not perhaps be generally realised that the common cuttlefish, *Sepia officinalis*, uses its siphon for slow swimming in all directions, as well as for the more violent backward leaps We recently had an opportunity of watching the behaviour of cuttlefish which were swimming at eye level and above our heads in one of the large tanks of the Plymouth aquarium We were rather surprised to notice that while moving slowly forwards with its fins undulating, the cuttlefish had its siphon curved back ventrally and was assisting its forward motion by emitting gentle squirts of water (Fig 1, A)

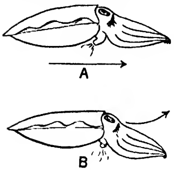

FIG 1

If the cuttle wished to turn to one side it would point its siphon opening to the opposite side and squirt a little more violently (Fig 1, B) In fact, for all its general slow movements the siphon appeared to be used, the undulations of the fins merely keeping the motion continuous and preserving the balance In the quick backwards swimming the fins were depressed along the side The siphon was extended about an inch and a half and could be pointed in any direction

Echo Sounding and Depths

IT is to be feared that the note on page 473 of NATURE of Mar 22 may lead to some misunderstanding and to conclusions unfavourable to the echo method of sounding Dr Maurer states that out of 254 comparative soundings made by wire and echo in water over 2000 metres deep no less than 36 showed differences exceeding 100 metres and that the maximum difference was 650 metres It should not be overlooked that a part, possibly a large part, of the error may be due to the curvature of the wire when the ship was drifting, for it is known that as a rule the depth by echo is less than that by wire even when the bottom is regular Dr Maurer also considers that the crude echo distance, calculated on a constant velocity, is more useful to the seaman for fixing his position

It scarcely seems probable that deep soundings would ever be used for fixing a ship's position, except possibly cable or surveying ships, so that to the ordinary navigator the difference between corrected and uncorrected soundings would be of no importance

In coastal water where the depth, or better, the rate of change of depth, gives valuable information in thick weather, the correction is of small practical importance when expressed in fathoms or metres except in some places such as the Red Sea Special warnings are inserted on the Admiralty charts in such cases

The Supplementary Hydrographic Conference, which was held at Monaco in 1929, resolved that all soundings should be corrected so far as possible before being placed on the charts, and did not adopt a standard velocity of sound in sea water

The Ions Produced by Discharges at Liquid Surfaces

WE regret that, in our paper (*Proc Roy Irish Acad*, 39, A p 21) in quoting Prof Zeleny's description of the discharge from an alcohol point in the form of a stream of minute drops, we did not make it clear that this description applied only to discharge under the conditions of instability indicated in his letter in NATURE of May 10 We are in agreement with Prof Zeleny that the discharge from a stable liquid surface is similar to that from a metal point, we find that it is carried by ions of the ordinary kind But although we have observed the conditions of surface instability and the transport of liquid mentioned by him, we have been unable, under the conditions of our experiments, using water and a number of alcohols, to find any evidence by Chattock's method of the big drag on the gas which discharge currents carried altogether by drops should produce We find evidence only of ions, which for a life of about 1/5000 sec have mobilities similar to those of ions produced in air by the ionising radiations

On the other hand in recent work, we have observed that in air drawn away from a discharging water point, there are present large ions having mobilities at least as low as those of the large ions of Langevin

Slug or Horned Viper?

As my name was mentioned by Prof T D A Cockerell in his letter in NATURE of May 17 on the identification of a certain animal represented among the incised carvings at Karnak, may I point out that the figure in question is the Egyptian hieroglyph for the letter F? I am informed by my colleague, Mr A Shorter, of the Department of Egyptian and Assyrian Antiquities, British Museum, that the animal portrayed in that symbol was identified as a slug so long ago as last century, the identification being based on a representation published by Prisse (1847), but that it has been more commonly recognised as the horned viper (*Cerastes cornutus* (Linn)) The 'horns' in the figure, if somewhat exaggerated, are like those of the viper and do not resemble the tentacles of a *Veronicella* (the slug which has been suggested), in which there are in fact two pairs of these appendages The clearly defined head and slender 'neck' which are shown in the Karnak figure are not found in *Veronicella*

Physics in Relation to Wireless *

By Dr W H ECCLES, F R S

THE preparatory research work for the transmitting station, that is, for generating electromagnetic waves, was done by Hertz in the years 1885–88, and appears to have been prompted by the rivalry between the extant theories of electricity and magnetism The laboratory work for the receiving station was done by Lodge in 1889, by Minchin and by Branly in 1890 Lodge's work on the reception of electric waves arose from observing that two metal knobs nearly in contact cohered when a spark occurred near them , Minchin's work was on light sensitive cells and his observations of the effects of electric waves was a side issue, but was duly recorded , Branly's investigations were on the diminution of the electrical resistance of contacts between oxidised metals and in masses of filings when sparks were made near by

Without asking which physicist we are to thank for each of the items needed for making a complete sending and receiving equipment for wireless telegraphy, we know that Oliver Lodge demonstrated the transmission of signals across a space of 30 yards and through several walls at the Royal Institution, London, on June 1, 1894 On this occasion a filings coherer was used, and the necessity of screening various portions of the receiver and its leads, which later became part of early wireless engineering, was emphasised Later in 1894, during the summer meeting of the British Association at Oxford, Lodge demonstrated the sending and recording of Morse code signals He used a Hertzian oscillator with large copper plates as capacity areas, an induction coil with the usual vibrating interrupter and a Morse telegraphic key in the primary of the coil As receiver he used a filings coherer with attached aerial wires for picking up the waves, a trembler of electric bell type operated by the coherer current and serving to shake the filings back to their non conductive condition, and a Morse inker for recording the dots and dashes on tape Other telegraphic instruments were employed as alternatives The following year Popoff, a Russian physicist, added to the recording apparatus a long earthed vertical antenna for catching natural electric waves produced by distant lightning discharges , he had possibly adopted the vertical wire from the patents of Dolbear and other American inventors

By 1895, therefore, every item was ready for the attention of the engineer , some parts of Lodge's apparatus had to be made more powerful, other parts more sensitive, and all of it more trustworthy and robust before it could be put into the hands of telegraphists for everyday use Improvements came rapidly, and the range of action was gradually increased, but progress was limited by the use of highly damped trains of waves At this date the spark gap at the sending station was situated in a long vertical wire, possibly surmounted by a large metal plate, and the coherer was in another similar antenna at the receiving station Such an arrangement had a high decrement and therefore *any* transmitting station affected *every* receiving station within range, and only one pair could work at a time

In Europe, so far as printed records can tell us, the earliest use of ' tuning ' coils in open oscillating circuits was due to Lodge, who appears to have satisfied himself by laboratory experiments in 1896 and 1897 not only that inductance coils were useful in a Hertzian oscillator for adjusting frequency, but also that their employment brought certain advantages over the method of adding capacity areas The main advantage of inductance over capacity in an open oscillator is that the former prolongs, the latter shortens, a strain of oscillations produced by a spark In consequence, if straight Hertzian oscillators be used as sending antenna and receiving antenna, and they be tuned to each other by inductance coils, the damping of each is made low and sharp resonance may be attained

Lodge's patent in 1897 embodying this principle produced a revolution in both thought and practice Hitherto it had been imagined that the electrical oscillations produced by the spark gap in the aerial possessed a very short wave length of the same order as the dimensions of the spark balls, just as in the case of the Righi oscillator , and the function of the transmitting antenna had been explained by supposing that the Righi waves ran up the wire and squirted out at the top This seemed to explain why high wires were needed for long ranges But now it was seen that the high wire vibrated as a Hertzian oscillator with a wave length of the same order of magnitude as the length of antenna, and that range of signalling was related to length of wave Moreover, Lodge's patent specification disclosed a scheme for exciting a metallically continuous antenna from a spark in a branch circuit, thus contradicting the accepted idea that radiation was impossible unless the spark was formed in the antenna Stranger still, the receiving antenna was shown as a continuous straight oscillator with its tuning coil acting as the primary of a high frequency transformer, the coherer being connected into the secondary circuit Being, in fact, a mine of scientific information and suggestion, Lodge's specification furnished during several succeeding years all the fundamental ideas employed by the engineers who developed commercial signalling plant of the spark type

In illustration of the last statement and to put on record another triumph of the laboratory, I may cite the important development known as the quenched spark transmitter The germ of this appears in Lodge's patent, where it is explained that an antenna would become a more persistent oscillator if it were excited by a short-lived spark in a side circuit The cessation of the spark automatically frees the antenna from the branch circuit

* From the presidential address to the Institute of Physics entitled The Influence of Physical Research on the Development of Wire, delivered on May 27

and from the dissipation of energy in it The idea was improved upon by Max Wein in 1906, who, for the purpose of his laboratory measurements, invented a form of gap that ensured rapid quenching This was developed by the Telefunken engineers into a type of transmitter that has seen world-wide service

From the year 1900 onwards the more alert workers in wireless sought about for a method of generating continuous waves The hope of achieving wireless telephony was the incentive, for no one at that time foresaw that continuous wave telegraphy by the Morse code could be better than spark telegraphy The problem was to devise a method of generating continuous waves of frequency at least 100,000 cycles per second The physicists' solution came from an unexpected direction, namely, from the scientific investigation of the properties of an electric arc traversed by alternating currents of low frequency In 1900, Duddell was pursuing these investigations on carbon arcs and happened to connect across the arc gap an inductance coil and condenser in series just as if the arc gap was a spark gap He was surprised to find that the arc whistled when ignited, and soon discovered that the pitch of the note depended on the magnitudes of inductance and capacity of the shunt circuit in the same way as in a spark circuit

The study of the oscillating arc was taken up by Poulsen in Denmark and he investigated the Duddell phenomenon when the arc burnt in various gases and between various electrodes By 1903 he discovered that an arc burning in hydrogenous vapour between a copper anode and a carbon cathode was capable of developing currents of frequency required for radio-telephony and of considerable power This splendid discovery led straight to practical radiotelephony

Fessenden invented the heterodyne method of receiving telegraphic signals The method relies upon the employment of a local source of electrical oscillations near enough in frequency to that of the incoming wave to produce in the receiving circuits regular increases and decreases of amplitude at an acoustic frequency The conception comes straight from the storehouse of acoustic theory, and could only have arisen in the mind of a student and teacher of physics, like Fessenden It is, in my opinion, one of the four or five universally important steps in the history of wireless technique

The most striking example of the discontinuity of the progress of wireless is afforded by the maturing of the amplifying vacuum valve

The first vacuum tube containing a hot filament and a separate electrode with external lead, that is, the first thermionic diode, was made by Edison in 1883 Studies of the thermionic current across the vacuum were conducted by Hittorf (1883), Preece (1884), Elster and Geitel (1887), and Fleming (1889 and 1896) Three years later J J Thomson's laboratory took up the problem and, in particular, O W Richardson during the next three years pursued his classical researches, usually employing a form of diode that has become typical, namely, a straight filament along the axis of a cylindrical anode Meanwhile an analogous form of diode in which the source of electrons is a photo electric surface was being similarly studied Many of the researches of the date were aimed at measuring the charge and the mass of the particles carrying the current across the vacuous space, and for this purpose other electrodes were sometimes introduced for deflecting the particles by an electric field Lenard, in 1902, used an anode of wire gauze so that light could pass through it to the cathode and liberate electrons, Wulf later used a flat spiral of wire, parallel to the photoelectric cathode for the same reason, Varley in 1903 observed that when the gas pressure was below about five microns the electrons could be accelerated towards a positive grid so as to be shot through the meshes of the gauze At higher pressures ionisation by collision occurred near the grid and gave such tubes their steep characteristic curves Besides all this experimental work of an abstract nature, various applications of the electric discharge through gases had been made to the rectifying of alternating currents Thus the scientific atmosphere of the first three years of the twentieth century was thick with material ready for useful applications

The first application of vacuum tube physics which I have to notice was made by the well known German physicist Wehnelt, who, having discovered in 1903 that filaments coated with oxides of rare earths emitted electrons copiously, patented a diode with coated filament as a rectifier in January 1904 He called this thermionic diode an electric valve It is sometimes said that Wehnelt invented the thermionic valve—but this is a fallacy, he invented the coated filament, and he invented the name, perhaps, but thermionic tubes with two electrodes had long been commonplaces in physical laboratories It is noteworthy that, apart from the valuable invention of the oxide coating, Wehnelt's application is widely used to day at many transmitting stations for rectifying alternating current and in the so called 'battery eliminators' of broadcasting sets About eleven months after Wehnelt, Fleming patented the combination of a thermionic diode, a coil and an indicating instrument, to form a circuit in which alternating current could be produced and rectified, special stress being laid on the applicability of the circuit for detecting by rectification the feeble alternating currents experienced in wireless receivers The diode as detector was in the field for several years as a rival to the electrolytic and contact detector The third interesting application of vacuum tube physics was made a year later by von Lieben, who proposed to utilise the lateral deflection of a stream of electrons as an amplifier The current to be amplified was intended to cause the deflection—either by charging an auxiliary electrode which then attracted or repelled the stream, or by producing a magnetic field The fourth application was made a year later in America by de Forest, who, by means of an auxiliary electrode in the form of a grid, controlled the passage of the electrons to an anode by accelerating or decelerating them in their line of motion

This method of control proved, in the course of a few years' development, more effective for amplifying purposes than the method of control by lateral deflection

The introduction of the von Lieben and the de Forest tubes is specially notable because these instruments were not alternatives to existing ones but were novel in purpose as well as in principle Von Lieben at any rate—de Forest seemed to be rather vague—clearly appreciated that an inertialess magnifying device was in his hands—the first distortionless repeater in history Unfortunately, neither form of instrument became an immediate practical success, perhaps because evacuation was not pushed far enough Von Baeyer was probably nearer success than either, for independently of de Forest, in 1907 he constructed a triode of ideal modern form containing a cylindrical anode two centimetres in diameter, a coaxial gauze cylinder one centimetre in diameter, and a filament in the common axis of the cylinders, and more highly evacuated than de Forest's tubes appear to have been But von Baeyer was engaged on the study of the motion of the electrons from the incandescent filament, and never applied the excellent amplifying functions which it undoubtedly possessed

The key to the situation was really lying all the time in Varley's remark in his 1903 paper, that electrons did not pass through the grid in quantity until the vacuum was below five microns However, during these years the physical laboratories intent upon the study of electricity at extreme exhaustions developed several methods of producing and retaining very high vacua In the years 1912 and 1913, Langmuir, working in the laboratory which also evolved the Coolidge X ray tube, gave the triode a more stable behaviour by resorting to extreme rarefaction

The technical value of the high vacuum triode rests upon its ability to magnify very small and very rapid electrical changes with close fidelity An electromotive force applied to the grid causes inappreciable current flow but liberates a magnified electromotive force in the anode circuit where relatively large currents are possible The development in size of triodic oscillation generators made them feasible for the transmission of signals, while small sizes improved reception—a remarkably happy concatenation

After this last revolution in wireless technique, later developments in the apparatus and methods of radio communication seem relatively undramatic For my present purpose I need only give one or two examples, with which I am very familiar, of the influence of the physical laboratory There are two methods of generating electrical oscillations for transmitting stations which have appeared as alternatives to the back coupled valve method, and have been adopted in large short wave stations all over the world The first is the crossed valve method, which was devised in the physical research laboratories of Finsbury Technical College in 1916–17 at the request of the Signal Experimental Establishment of our War Office It was intended for use over short distances behind the trenches on wave lengths of 50 metres and less

The second method aims at generating electrical oscillations of very constant frequency by aid of massive bodies sustained in mechanical vibration by triodes The earlier apparatus for this purpose was the tuning fork alternator, which was developed in 1918 for delivering fundamental and harmonic frequencies for the purposes of measurement in the physical laboratory A later apparatus arose out of the growth of supersonic under-water signalling in 1917 In the autumn of that year Langevin in France and Rutherford in England independently suggested that the piezoelectric qualities of quartz might be utilised for perceiving the arrival at a receiving station of pressure waves in water and for producing such waves at a transmitting station Langevin's work at Toulon was supplemented by his collaborators at Finsbury Technical College and Harwich, and at Finsbury this led, first, to an appreciation of the fact that quartz vibrating under the stimulus of a feedback circuit steadied the electrical oscillator, and, later, to a triode circuit for automatically sustaining quartz in vibration at its natural frequency in water without the use of back coupling At about the same time, we learned later, Nicholson in the New York laboratory of the Western Electric Company, devised an equivalent method of vibrating piezoelectric crystals such as Rochelle salt in air by aid of a triode Thus came about what may be called the marriage of mechanical and electrical oscillations, the so called 'stabilisation of frequency', which plays so large a part to day in wireless stations, large and small

My account of the contributions of physicists to wireless omits all reference to the great engineers who have adorned the industry, as otherwise this address would become a complete history of wireless, but I must refer to the effect upon practical wireless of the study of the electrical properties of our atmosphere—a branch of geophysics—which has already assisted practical operation of telegraphic circuits In Great Britain the study has been pursued under the auspices of the Radio Research Board and independently by T L Eckersley In my opinion the cumulative effects on radio communications of these researches will disclose itself in the near future

A valuable geophysical discovery made neither by physicists nor engineers was the phenomenon that short waves could travel long distances Short wave transmitting and receiving apparatus was much used during the War, for example, 50 metres for trench sets and less than 20 metres for aeroplanes, in several of the belligerent countries, short waves had been tried for telephony across a hundred miles of the North Sea and between London and Birmingham overland, but were not suspected of shooting aloft and coming down thousands of miles away We now know that trials made within the skip distance were inevitably misleading However, before 1920 all the technique of short wave telegraphy and telephony was complete As a mere chance, amateur wireless enthusiasts were officially relegated in most countries

to transmission experiments on waves shorter than 300 metres Gradually widely scattered amateurs began to overhear signals exchanged between two very distant colleagues In 1921, American amateurs transmitted to British amateurs on wave lengths of 200 metres, this was reciprocated in 1922 Meanwhile the American amateurs had found shorter waves better, and in 1923 were communicating easily with other amateurs across world-wide ranges The first commercial application was made in the autumn of 1923 and has been followed by universal adoption of short-wave signalling It is a remarkable example of a revolution in method which was not due to, and did not require, any change of technique—a revolution effected by pure discovery

The Concept of Space

ON Friday, June 6, Nottingham was honoured by a visit from Prof A Einstein, who delivered a lecture (in German) in the Great Hall of the University College After each section an English translation was given by Dr H L Brose The chair was taken by Prof H H Turner The lecture was an account of the history of the concept of space, and was addressed to a general audience At the end questions were invited those received were all concerned with the present position of the unitary field theory For the following impression of the lecture I am deeply indebted to Miss Dallas and Miss Lieber for their help, but for any inaccuracies I alone am responsible

At the outset Prof Einstein emphasised that he was not making an authoritative pronouncement, but merely stating his own personal opinions He believed that the fundamental concept of physics was that of the rigid body The idea of space was not acquired until a much later date, and was not known to the ancient Greeks Euclid's geometry, in particular the part dealing with the congruence of triangles, was based upon notions of rigid bodies, such as measuring rods which could be moved about as a standard of comparison Motion appeared first, not as in space, but as that of one body relative to another The concept of space was introduced by Descartes, the founder of co ordinate geometry This was a purely mathematical notion, without any physical implications, and concerned only with the geometrical aspect of the relative position of two or more bodies The other aspect of space was due to Newton, who considered the bodies, not at rest, but in motion To deal with the problem of acceleration he introduced the idea of an absolute space, forming a framework by which the motion of the bodies could be measured, but itself quite unaffected by those bodies It was a wonderful thing that Newton's genius enabled him to realise the definitely physical reality of space This reality has been neglected or misunderstood by many of his successors, including the philosopher Kant

However, in Prof Einstein's opinion, the really decisive change from the geometrical to the physical conception of space was due to Faraday and Maxwell, who considered electromagnetic phenomena to have their seat in the ether, and spoke of the field or the state of this ether as affected by electro magnetic action Why did they think it necessary to use a new word ether, when the old one space was already available ? The reason, no doubt, was that they were fettered by the ideas prevailing in their day, and had not realised the connexion between the space of geometry and the space of physics As material bodies were the first objects to be considered in physics, they introduced the idea of a material ether to replace what was formerly considered as empty space, through which electro magnetic action took place This idea was developed by Lorentz, in whose view all electromagnetic action, even that in the interior of material bodies, really took place in the ether Thus he deprived matter of all its electromagnetic properties, but to compensate for this he deprived ether of all its mechanical properties, and attributed a capacity for motion only to the elementary particles of matter

The next modification was the special theory of relativity Classical physics used three co ordinates in space and one in time It was now found necessary to unite these into the four co ordinates of space time, and to give up the belief that events could be divided into categories of 'before', 'simultaneous', and 'after' This prepared the way for the general theory of relativity, which dealt with the phenomena of inertia and derived the laws of motion from the geometrical structure of space, or rather of space time, thus uniting geometry and physics in a new intimacy The experimental verification of this theory is well known We have now come to the conclusion that space is the primary thing and matter only secondary, we may say that space, in revenge for its former inferior position, is now eating up matter

With regard to the unitary field theory, the purpose of which was to derive all physical phenomena, electromagnetic as well as gravitation, from the properties of space, Prof Einstein confessed that his colleagues did not agree with him In fact, he added with a smile, they think that I am crazy on this subject However, he himself had faith that the idea (which came to him during a severe illness two years ago) of attributing direction as well as metrical structure to space would ultimately lead to success in obtaining a single theory to embrace all phenomena He regarded this as a true physical theory, not as a mere mathematical curiosity It was best to leave aside the difficulties of the quantum theory for the present, but he hoped that when the simpler problem of

matter in bulk was solved the more difficult ones relating to atomic physics could speedily be dealt with The urgent thing at present was to obtain the equations of motion of an electron or proton Although the theory was not yet finished, he firmly believed that the end was very near

Amid enthusiastic cheers, Alderman Huntsman, chairman of the College Council, announced that the blackboard used by Prof Einstein and signed by him would be varnished and preserved in memory of a historic occasion

H T H PIAGGIO

Obituary

PROF K J P ORTON, FRS

HIS friends even now find it more than a little difficult to realise that they have looked their last on Kennedy Orton—his vigour and freshness of mind and body, his keenness in attack on any problem, scientific or administrative, had suffered so little diminution with the passing of the years, that those who knew him well looked forward with no thought of the end to that stimulating interchange of ideas, to those talks ranging from China to Peru, which now are fated to remain but cherished memories

Orton was a born man of science Intended for a medical career, he found that the microscopical work involved was likely to prove too severe a tax on his eyesight, and he turned to the study of pure chemistry As a scholar of John's he worked at Cambridge from 1891 to 1895 under Liveing, afterwards proceeding to Heidelberg, where he took his doctor's degree *summa cum laude* Victor Meyer's attractive personality left a deep mark on Orton's character, and one is tempted to speculate on the rapidity of thought, the energy and versatility, the power to pick out underlying resemblances from surface differences, the single hearted devotion to the pursuit of knowledge for its own sake, which were common characteristics in the mentalities of master and scholar

He returned to London master of a wide range of chemical philosophy, and already interested in the properties of and mechanism of substitution in halogen compounds of benzene derivatives, well versed in laboratory technique, a skilled worker in glass In truth, he always retained keen interest in carefully planned and neatly executed laboratory work, and if ever he showed appreciation of his own powers it was when, with justifiable pride, he recalled instances of the evolution of skilful and enthusiastic researchers from distinctly unpromising material

For six years he worked as demonstrator in chemistry at St Bartholomew's Hospital, and in 1903 he was appointed to succeed Dr J J Dobbie in the chair of chemistry in the University College of North Wales The deep and accurate knowledge, the administrative ability, the sympathy for, and understanding of the student mind that he brought to his task at Bangor are well known to those whose good fortune it was to serve with him or to be taught by him, and his election to the Royal Society in 1921 testified equally to the value of his own researches and to the influence of the school of chemistry which he directed

Orton's output of research was large—the general index of the *Journal of the Chemical Society* marks sixty-two titles under his name between 1897 and 1922 Looking over these and his later papers, one is struck by the clearness of their outlook—there is a refreshing absence of ragged edges, of untidiness or diffuseness of thought, diction, or method The problem is clearly stated, attacked by well planned experiments, and the result, positive, negative, or doubtful, is set out in vigorous language free from the slightest trace of ambiguity

Substitution in aromatic compounds, and the problems involved in the theory of the intramolecular migration of atoms had early occupied his attention, and during his time in London he had, in conjunction with Chattaway, attacked such problems as the substituted nitrogen chlorides and their rôle in the halogenation of anilides and anilines About this period, too, his work on the action of light on nitrogen iodide shows his interest—an interest which never left him—in the efficacy of light in promoting chemical change

A remarkable research, carried out at Bangor, showed that the migration of halogen in substituted acyl anilides is dependent on the intermediate liberation of chlorine,

$$C_6H_5N\,Cl\,Ac + HCl \rightleftarrows C_6H_5NHAc + Cl_2 \\ \longrightarrow C_6H_4Cl\,NHAc + HCl$$

This work threw great light on the mechanism of the reaction, and confirmed Armstrong's general view that hydrochloric acid is the catalyst Orton turned again and again to the consequences of this work, developing therefrom a method for the regulated chlorination of aromatic substances, and for the production of an acetic acid solution of known chlorine concentration

In collaboration with his students he carried out much valuable work, involving studies of the mechanism of acetylation and of halogenation, on acetic acid and acetic anhydride He consistently applied physico-chemical methods to the elucidation of the mechanism of organic reaction, and in some of his later work turned to the more purely physical side of his science, as is shown by his development with D C Jones of the technique of work on the mutual miscibility of liquids and of the determination of critical solution temperatures of ternary mixtures as a criterion of purity

Orton was, however, much more than a chemist, and any survey of his activities limited to the chemical side of his life's work would present but a warped view of his character His busy life left him but scant leisure, and the greater part of such spare time as he could command was devoted to

rock-climbing and to the study of the habits and movements of birds In this last-named region he was an acknowledged authority, and though his chapter on "Bird Life in the Mountains" in Carr and Lister's "Snowdonia" gives some adumbration of his powers, it is a matter for regret that he has not left more detailed records of his bird lore

Withal he had a critical knowledge of much that is best in our national literature, and, realising his reticence in certain directions, his intimates discovered with keen pleasure that a treasured volume of Arnold's poems was a constant companion in his wanderings over the Sussex downs

Orton's view of the function of a university was no narrow one, and he saw, more clearly than many men of science, the danger of losing the cultural value of a university training that comes from laying over emphasis on the specialist's work and on that technological side of a student's labours which is concerned with preparation for living rather than for life His interest in his students was unflagging and their graduation did not set a period to that interest On more than one occasion has an old pupil found the helping hand out stretched even before he had thought of turning to his teacher, and, veteran or recruit, no one could go to Orton for advice or help without feeling that he was giving of his best

Truly his days were in every sense full ones, and if in rare moments depression seized him, it was because he, more than most, realised what deep significance Νὺξ γὰρ ἔρχεται bears

> For at my back I always hear
> Time's wingéd chariot hurrying near
> And yonder, all before me, lie
> Deserts of vast eternity

It is small wonder that, urged by his ever present sense of the fleeting of time, he so grievously over taxed his natural powers that pneumonia found him with no reserve of strength to resist its advances, so that after a few days' illness he died peacefully on Mar 16

He rests in a wind swept Anglesey churchyard, with the waters of the Menai lapping at his feet, and the mountains he knew so well heaving aloft their vast masses on the sky line Deeply as we mourn the cutting-short of a life in the plenitude of its powers, regret is assuaged by the thought that Orton had crowded into his fifty-seven years a record of work well worthy of one privileged to live beyond three-score years and ten

ALLAN FERGUSON

MR A S HIRST

MR ARTHUR STANLEY HIRST, whose death at sea on May 4 was reported from Colombo, was formerly an assistant keeper in the British Museum (Natural History) He was born in 1883, and was the son of the late Dr Albert Hirst, of Hackney He was educated at Merchant Taylors' School and studied zoology under the late Prof Minchin at University College, London

On entering the service of the British Museum, Hirst worked for some time in the mammal room, but was afterwards placed by Sir Ray Lankester in charge of the collections of Arachnida and Myriopoda He studied various sections of these extensive groups and published a long series of systematic papers on them, but latterly he gave his attention almost exclusively to the Acari or mites, the economic importance of which has led in recent years to a great increase in the number both of specimens and of inquiries reaching the Museum Hirst's papers on the Acari were marked by great accuracy of description and laborious investigation of detail Many of them contain facts and suggestions which will one day be found to have contributed much to a scientific knowledge of the group Especially noteworthy were his identification of the adult form of one of the familiar and troublesome harvest bugs, his demonstration of a tracheal system in the group of mites named from the supposed absence of the system the Astigmata, and his description of the fossil arachnids from the Rhynie chert, the oldest known air breathing animals

For some years Mr Hirst's health had been unsatisfactory, and in 1927, under medical advice, he resigned his post at the Museum to seek relief in the drier climate of Australia While there he carried on his work on Acari, mainly at the University of Adelaide It would appear, however, that the relief was only temporary, and his death occurred while he was on his way home to England

W T C

News and Views

ON June 5 the Lord Mayor of London unveiled the third of the three windows which have been placed in the little church of St Ethelburga the Virgin, Bishopsgate, to the memory of Henry Hudson the explorer It was in this church that Hudson and his crew communicated on April 19, 1607, before setting out on his first voyage Three years later, in 1610, with faith undimmed by three failures, "he sailed from London in the *Discovery* and met his mysterious and tragic end His men mutinied and put their captain with eight of the crew out of the ship to perish That incident, which took place in June 1611, is the one chosen for the subject illustrated in the third window The first window, unveiled in 1928, was the gift of the Hudson Bay Company, the second was given by some American citizens, while the third is the gift of the citizens of the British Empire

THE firm of Messrs W H Allen, Sons and Co, Ltd, of Queen's Engineering Works, Bedford, has long been known for its systems of training both for engineers and workmen Engaged in the construction of high class machinery for power plants, pumping installations, and for naval and mercantile vessels, and employing some two thousand men, the firm has a constant need for highly trained engineers as well as skilled craftsmen, while the variety of work done provides wide experience for the beginner The

present head of the firm, Mr R W Allen, was president of the Institution of Mechanical Engineers in 1928, and in his presidential address he referred to the question of engineering training and education, which in the future, he said, would have three very important and difficult tasks First there was the problem of a suitable training for administrative and managerial positions, which involves not only a knowledge of scientific principles, technical applications, and workshop processes, but also calls for a knowledge of men and a broad view of industry, then there was the problem of the production of craftsmen through apprenticeship, and thirdly there was the training of boys other than craft apprentices This last category, he said, has been singularly neglected, "but we are realising to-day that from this class of entrant to industry there will be drawn in the future the great majority of the operatives of process work"

How Messrs Allen have solved these problems is explained in an illustrated booklet recently issued by them entitled "Engineering Training" Briefly, there are four schemes of training dealt with, known respectively as engineering pupilage, senior engineering studentship, junior engineering studentship, and trade apprenticeship, the first being suitable for the university graduate and the last for the elementary schoolboy Much information is given concerning the time spent in the various departments, the hours of work, wages, holidays, and the like, and an interesting coloured chart shows how the trade apprentice can become a student and how the junior student can become a senior student But a youth entering Messrs Allens' not only finds an excellent system of practical training laid down for him but also through the works Education and Welfare Department he is provided with courses of lectures on mathematics and science and on design and production, some of the lectures being given by the heads of departments There is also a Junior Engineering Society managed by the pupils, students, and apprentices, a past and present students' association, and everything is done to encourage healthy mental and physical culture The booklet is one which should be of use to all interested in engineering education especially as it embodies an account of a system worked out with great care which has stood the test of time

IN the earlier part of his presidential address to the Linnean Society of New South Wales, delivered at the annual general meeting on Mar 26 last, Dr H S Halcro Wardlaw reviewed the work of the Society during the past year The notable feature was the successful conclusion of negotiations for the erection of Science House by the Royal Society of New South Wales, the Linnean Society of New South Wales, and the Institution of Engineers, Australia The building is to be in Sydney on a site specially granted by the Government of New South Wales It will be a six storey building and, it is hoped, will be completed by the end of the year Another point of wide interest in Dr Wardlaw's address was that the Council of the Society has approved of a scheme to publish, two or more times a year, coloured plates of species of the Australian flora It was also stated that scientific societies have gained representation on the National Park Trust of Australia in the appointment of Prof T G B Osborn, professor of botany in the University of Sydney, to fill a vacancy The Government of New South Wales has again continued the protection granted to species of wild flowers threatened with extinction, while, as one result of Dr Walkom's attendance at the South Africa meeting of the British Association, the Society has taken steps to attempt to secure the setting apart of an area or areas for the protection, cultivation, and exhibition of the native flora

THE second part of Dr Wardlaw's address was devoted to a consideration of some aspects of the adaptation of living organisms to their environment Dr Wardlaw said that a characteristic feature of living organisms is the possession of mechanisms which protect them against the effects of changes of their environment These mechanisms in the earlier forms exert their action by restricting the interchange which they allow between the organism and its surroundings As they develop in efficiency, they become more selective in action, and are able to preserve the essential characters of the organism while allowing a free interchange with its environment As the complexity of organisms has increased, they have rendered themselves more independent of their external environment by providing their cells with an immediate environment of their own By this means external changes are only allowed to reach the cells in a modified form The evolutionary development of the adaptive mechanisms of the organism has continually extended the range and scope of its control over its environment Examples of the most highly specialised forms of this control are the maintenance of a constant body temperature by homoiothermal animals, and the provision of a special food supply for their young by mammals As the effectiveness of the mechanisms for the adaptation of the environment to its needs has increased, the use of adaptive modification of the organism itself has correspondingly diminished This is especially the case with man, in his ability to make tools, and in extending and increasing his control over his environment so much more rapidly than would seem possible by evolutionary modifications of bodily structure

DR B T DICKSON, the first Chief of the Division of Economic Botany, has issued his first annual report as director of the activities of this new scientific venture of the Australian Council for Scientific and Industrial Research (Pamphlet No 14, Melbourne, 1929) With, as yet, but few staff appointments made, and working in temporary quarters, the activities of this division can scarcely be regarded as fully under way, but the report indicates the lines on which work will be prosecuted, and records good progress, especially in research into some of the serious diseases attacking economic crops Dr Dickson outlines a programme of work which includes improvement of existing crops by controlling and eradicating disease, by selection and breeding, and by improved nutri-

tion; the introduction of new plants as the result of exploration or exchanges, and the testing of such plants; the control of weeds; the survey of the plant resources of the Dominion and the records of survey and improvement by adequate herbarium material. It is a comprehensive programme which indicates in an interesting manner the importance of scientific study of the flora of a country. Along some of these lines, as in most plant physiological questions, no start can be made until more resources in men and laboratories are available, but interesting sections of the report, such as that dealing with the effect of harvesting fruit when mature in controlling bitter pit in exported apples, show that on some lines the Division is already doing valuable work to justify the enterprise of the Commonwealth authorities in calling it into existence.

WE are glad that the General Electric Co. Ltd., following the example of several similar manufacturing firms, is now publishing a journal recording its many scientific and technical activities. The researches carried out in its laboratories at Wembley often pass over the borderland of engineering into that of pure science and are of special interest to the scientific world. They also help to keep the undertaking in close contact with the technical colleges and universities from which the Company gets the freshly trained minds necessary for the progress of the engineering industry. The first number is the May issue and it gives amongst other interesting articles a résumé of the electrical progress made during the year 1929. The national grid, 'talkies', illumination, broadcasting, and electric traction have provided numerous problems which the Company has successfully solved. A picture is shown of the plant at Wembley used for testing the great lattice towers used for the grid. Eight pulls of fifteen tons each are applied to them in one direction at various points and a further eight pulls of ten tons each are applied at right angles to the first set. Apparatus has been devised utilising photoelectric cells for the measurement of colour temperature and luminous output. As both temperature and lumen (candle power) scales are linear, the calibration of the apparatus is very simple. The very minute neon indicator lamps the Company has perfected, which take only the hundredth part of the current of an ordinary lamp, should prove useful for showing whether circuits used for cooking, heating, etc., are connected or not, and also for indicating in the dark the position of any object such as a switch. In addition, the Company makes ten kilowatt lamps for use in cinema studios each equal to 200 ordinary lamps. Details are also given of the large turbo alternators the Company constructed and of the 350 h.p. Diesel electric locomotives made for the India State Railways.

THE Annual Report of the Royal Scottish Museum for 1929 indicates the advance that one has come to expect from that progressive institution. Two new halls have been opened, one containing collections of European arms, the other beasts of prey, and exhibits are being prepared for a new gallery which is to be devoted to the illustration of evolution. For the second year in succession the number of visitors has exceeded half a million, and the average attendance on the three open hours of Sunday afternoon exceeds 4000, an indication of the popularity of the collections. It says little for the appreciation in which the Royal Scottish Museum is held in official quarters, that the annual report of this important adjunct to the education of young and old in Scotland should not be regarded as worthy of printing. The typewritten copies are unimpressive in appearance, awkward in size, and are unlikely to be stored away as annual reports of this kind should be, for comparison with their predecessors in tracing the development of the Museum.

THE national museums of Great Britain have still to formulate a serious policy for the encouragement of children, and while they hesitate or, as in the Royal Scottish Museum, make somewhat feeble and tentative efforts, it is informative to glance at another example of the progress made in the United States. A section of the Annual Report for 1928–29 of the Peabody Museum of Yale University is devoted to the Children's Department. A staff of three ladies is set aside by the Museum authorities for this work and an entire house has been acquired for the Department's use. The result is that on an average four classes a day from the schools in New Haven have been entertained and informed in the Museum. Of the 65 public schools, 55 have visited the institution for lectures or tours. In all, 455 groups have had the services of one or more *docents* in the Museum during the year, and in addition one of the staff has spoken to 130 classes in the city schools. It is a record which will bear abundant fruit in the interest which the children will take in the Museum and its collections in later years.

CONSIDERING the large number of waterfalls there are in Africa, it is at first sight strange that the total hydroelectric power generated there scarcely amounts to the output of a first class steam power station. When it is remembered, however, that there is little demand for power near any of the big falls, and that there are great seasonal and year to year variations in the flow of water, which would necessitate the construction of large and costly reservoirs, it will be seen that at present there is no great scope for commercial hydroelectric power stations. In certain parts of Africa the high evaporation from reservoirs is a serious drawback. There are water power stations at Katanga and Northern Rhodesia in connexion with copper mining. In South Africa, where great commercial developments have taken place, there is an abundant supply of cheap and easily worked coal. The Witwatersrand goldfield, for example, has an excellent coal field quite close to it. It is interesting to learn that the negotiations between the Tanganyika Government and the Power Securities Corporation for the development of the Pangani Falls have been satisfactorily concluded. The power developed at these falls is sufficient to provide the entire region of Tanganyika Territory between the Great Lakes and the Indian Ocean with electric power. The scheme appears to be a good one and cheap power would

stimulate agricultural and industrial development There is a small station at Dar es Salaam which uses fuel carried long distances by sea, but it is incapable of coping with the demand

A MOST important problem that electricians have to solve is to invent a device which will prevent the electric pressure between high pressure supply mains or between one of them and some other conductor from attaining such a value that a spark may ensue and the consequent arc cause a breakdown of the supply system The sudden rise of pressure may be due to atmospheric electricity, lightning discharges, or impulsive rushes of electricity due to a sudden alteration of the load on the network A great variety of lightning protective devices and electrical 'safety valves' are in use, but none is entirely successful Most of them want constant attention, and some of them are objectionable to have in a power station owing to the liquids they contain We are interested therefore to learn from a *Daily Science News Bulletin* recently issued by Science Service, Washington, D C, that a new material called 'thyrite' has been discovered which is practically an insulator at low voltages but becomes a conductor when the pressure is high The substance, we are told, includes carborundum, and a sample of it had a resistance of 50,000 ohms at 100 volts, and at 10,000 volts its resistance was half an ohm The change in the resistance appears to take place gradually and not suddenly It would therefore not be very useful as a safety valve between two high pressure mains It might be very useful, however, in some form of lightning protector Thyrite resembles black slate in colour and its mechanical properties are analogous to those of dry process porcelain In manufacturing, the material can easily be moulded to the shape required The contact surfaces are coated with metal by the Schoop metal spraying process

A CURIOUS problem of bird flotation was raised by F H Alexander at a meeting of the Challenger Society at Cullercoats on May 2 last He found that the body of a bird, without feathers, has a specific gravity nearly equal to unity, but since a bird does not float without its feathers, such a statement has little practical bearing He further stated, however, that the high freeboard with which most birds float is not easily accounted for, since actual measurements of the underwater volume of floating birds showed that they displaced a volume of water equal only to one third or even one-quarter of their own weight Various suggestions are made as to the powers which may aid ordinary displacement in supporting the bird—perhaps surface tension, perhaps special use of the internal air sacs, perhaps an unknown power of 'levitation' Our own impression is that Mr Alexander's data are faulty Birds have the power of raising their feathers at will, and in water-birds, in which the feathers are kept well oiled, this means a large increase of volume impenetrable to water, in other words, a much greater displacement than would be suggested by measuring a dead or living bird in the hand The only means of obtaining the displacement of a floating bird is by measuring the water displaced, and this simple check Mr Alexander has not employed Until that is known all speculation based upon calculations made upon a bird out of the water seems to us to be of little value

MUCH has been heard of the alleged Maglemose harpoons found by the late Beaumont Morfitt at Skipsea and Hornsea But surely their last appearance as genuine finds of the period claimed for them must be that in the *British Museum Quarterly* for April, where without a word of caution they are described as "mesolithic harpoons" The authenticity of the discoveries has always been doubtful There should no longer be any doubt if the new evidence brought forward by Mr T Sheppard in *The Naturalist* for May is accepted He states that a sister of the finder of the harpoons told him, in the presence of others, that her brother Beaumont made these harpoons from the leg bone of a red deer he had found in the peat, that he boiled them in glue, and invented the story of their discovery It is to be regretted that this story was not submitted to the Committee which inquired into the authenticity of the weapons

THE Society for Constructive Birth Control and Racial Progress founded a 'Mothers' Clinic' for the instruction of normally formed women in simple measures for the control of conception An analysis of data from ten thousand cases attending this clinic, compiled by Dr Marie Stopes, has been published Of the 10,000 women attending, 9912 were married, 5 only were unmarried and already mothers, and 83 were betrothed couples about to be married Among the cases, a considerable number desired the knowledge to enable them to space their later and desired children, and 142 childless women sought help towards securing pregnancy Valuable data have been secured of the numbers of pregnancies, live children, and miscarriages that have occurred among these women Cases with lacerations of the cervix uteri numbered 1321, this injury is prone to develop cancer, so that its early recognition and treatment are important

THE Prime Minister has nominated Mr J H Whitley, formerly Speaker of the House of Commons, to be chairman of the British Broadcasting Corporation in succession to Lord Clarendon, who recently resigned

EARL BUXTON, from 1914 until 1920 High Commissioner and Governor-General for South Africa, has been awarded the African Society's Gold Medal This medal is awarded from time to time to those who have rendered eminent services either for or in Africa Lord Buxton has been for ten years president of the African Society

SIR HENRY G LYONS, has been reappointed Director and Secretary of the Science Museum, and will hold that office until October, 1933 Sir Henry was originally due to retire last October, on attaining the age of sixty five, but was invited by the Board of Education to retain his post for a further year

THE Huxley memorial lecture of the Imperial College of Science and Technology next year will be delivered by Sir A Smith Woodward, on "Modern Progress in Vertebrate Palæontology," in the Royal College of Science, Exhibition Road, S W 7, on Monday, May 4, 1931, at 5 30 P M

THE Albert medal of the Royal Society of Arts for the current year has been awarded by the Council, with the approval of the president, H R H the Duke of Connaught, to Prof Henry E Armstrong, "for his discoveries in chemistry and his services to education" The medal was founded in 1863 as a memorial to Prince Albert, for eighteen years president of the Society, and is awarded each year "for distinguished merit in promoting Arts, Manufactures, and Commerce"

THE following appointments have recently been made by the Secretary of State for the Colonies Mr D W H Baker, to be superintendent of agriculture, Nigeria, Mr A B Harper, to be produce inspector, Nigeria, Mr A K Gibbon, to be assistant conservator of forests, Nigeria

THE Microscopical Society of Wales held its inaugural meeting at the Technical College, Cardiff, on June 4, when the following officers were appointed *President* Dr H A Harris, *Vice Presidents,* Dr David Hepburn, Mr Clarence A Seyler, *Chairman,* Dr James Beatty, *Secretary,* Mr Alfred E Harris, *Committee,* Mr J Malcolm Davies, Mr Donald Hicks, Mr W T Lane, Eileen Melville, Mr E A Rudge, Mr J H Wilson, *Treasurer,* Mr L Osborne Davis The office of the Society is at 27 Park Place, Cardiff

THE reviewer of "The Time Journey of Dr Barton," in NATURE of May 31, while sympathising with the prospective developments described, remarked that the work "does not face the real issue", that is, the manner in which individual rights, aims, and prejudices are to be co ordinated for obviously desirable ends Mr John Hodgson, the editor of Dr Barton's manuscript, writes to say that Chap xxix (entitled "The New Control") is devoted to the consideration of this vital point

A PARAGRAPH in our "News and Views" columns of May 31 recorded a television performance given before an audience of 500 people in New York The screen used was six feet square A note from the Baird International Television, Ltd, 133 Long Acre, W C 2, reminds us that television was projected upon a large screen in England so far back as December 1928, when Mr Baird showed images on a screen 4 ft by 4 ft At present sight and sound are being broadcast daily by the British Broadcasting Corporation, and Great Britain is the only country in the world which has an official and regular service of broadcast sight and sound, and where 'televisors' are available to anyone who cares to purchase them

THE Report of the Water Pollution Research Board for the year ended June 30, 1929, has been issued (Dept Sci Ind Research London H M Stationery Office, 9*d* net) It contains the report of the director of water pollution research with details of investigations on the purification of beet sugar factories' effluent It is believed that by a process of biological filtration more than 90 per cent purification of beet sugar factory effluents can be effected

WE have received catalogues of second hand microscopes and accessories and of 'optical utilities' from Messrs W Watson and Sons, Ltd (313 High Holborn, W C 1) The former includes objectives having the exceptionally high N A of 1 5 and 1 6, also recent microscopes and accessories and books, the property of a distinguished microscopist Among 'optical utilities', the 'window telescope', the 'Univis' bi and tri focal spectacle lenses, and the 'Speera binocular magnifiers are of interest

THE causes of neo natal death is the subject of a report by Dr J N Cruickshank issued by the Medical Research Council (*Special Rep Series,* No 145 London H M Stationery Office, 1*s* 6*d* net) In 800 cases of neo natal death (that is, death of the infant between birth and the end of the fourth week) examined, the cause of death was considered to be birth asphyxia, birth injury, or prematurity in 540 cases, infective conditions in 238 cases, and gross developmental defects in 22 cases Asphyxia at birth is thus an important cause of neo natal death, and Dr Cruickshank devotes a section of his report to a consideration of recent advances in the treatment of the condition

THE Ministry of Health has issued an eighth report of the Advisory Committee on the Welfare of the Blind, 1928-29 (London H M Stationery Office 6*d* net) The total registered blind population of England and Wales in 1929 is 52,727, as compared with 46,822 in 1927 and 30,785 in 1920, being ratios to the general population of 1 749, 1 835, and 1 1219 respectively It is considered that this apparent increase is mainly due to better registration and not to an actual increase of blindness Juvenile blindness (0 5 years) has not increased but has remained almost uniform during the last five years The bulk of the increased number of blind persons is accounted for by the increase among those above fifty years of age, and it is suggested that there is a fruitful field for inquiry into the whole question of the care and preservation of the sight of the adult population

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —Forest officers and estate officers, each on probation, under the Forestry Commissioners—The Secretary, Forestry Commission, 22 Grosvenor Gardens, S W 1 (June 16) A radium custodian for the Hull Radium Trust—The Chairman, Hull Radium Trust, Royal Infirmary, Hull (June 17) A woman assistant in the Agricultural Department of the Surrey Agricultural Committee, to work under the small livestock instructress, and an assistant instructor in agriculture in the Agricultural Department of the Surrey Agricultural Committee—The County Agricultural Officer, Agricultural Department, County Hall, Kingston on-Thames (June 18) A lecturer in electrical engineering at the Dudley Technical College—The Director of Education, Education Offices, Dudley (June 19) An

assistant lecturer in geography in the University of Durham —The Secretary of Council, University Offices, North Bailey, Durham (June 20) A lecturer for biology, general science, and hygiene at the Kenton Lodge Training College for Women, Newcastle upon Tyne —The Director of Education, Northumberland Road, Newcastle upon Tyne (June 21) A teacher of mechanical engineering subjects at the Technical College, Wolverton —The Principal, Technical College, Wolverton, Bucks (June 23) A head of the Building Department of the Birmingham Central Technical College — The Principal, Central Technical College, Suffolk Street, Birmingham (June 25) An assistant lecturer in mathematics at the Brighton Technical College —The Secretary, Brighton Education Committee, 54 Old Steine, Brighton (June 28) A lecturer in electrical engineering, and an assistant lecturer in mechanical engineering, at the Manchester Municipal College of Technology—The Registrar, College of Technology, Manchester (June 28) A technological chemist under the Ceylon Coconut Research Scheme, for work on the chemistry of the coconut and its commercial products —The Agricultural Adviser to the Secretary of State for the Colonies, 2 Richmond Terrace, Whitehall, S W 1 (June 30) A lecturer in mathematics at the Northampton Polytechnic Institute —The Principal, Northampton Polytechnic Institute, St John Street, E C 1 (June 30) An assistant Government analyst for Hong Kong —The Private Secretary (Appointments), Colonial Office, 2 Richmond Terrace, Whitehall, S W 1 (June 30) Junior assistants at the National Physical Laboratory — The Director, National Physical Laboratory, Teddington (June 30) Three research fellowships at the Onderstepoort Veterinary Research Laboratory, Pretoria, respectively for work on tissue culture and filterable viruses, bacteriology, and the physiology of animals, especially ruminants, and the extraction of toxic substances from plants and the determination of the nature of such substances— The Secretary, Empire Marketing Board, 2 Queen Anne's Gate Buildings, S W 1 (Sept 1) A junior assistant chemist under the Research Association of British Flour Millers—The Director of the Association, Old London Road, St Albans Teachers for evening classes in physics, heat, light, and sound advanced, photography, building construction, geometry, and graphics for building students, calculations for builders, building science, and for plaster work, at the Woolwich Polytechnic—The Principal Woolwich Polytechnic, S E 18 A laboratory assistant in the Research Department, Woolwich—The Superintendent, Research Department, Woolwich, S E 18

Our Astronomical Column

Absolute Motions of Stars - *Astr Nach* No 5696–5697 contains a catalogue of the absolute velocities of 1937 stars, by R Klumak and F Hecht The radial velocities are taken from J Vouto's Second Catalogue of Radial Velocities (Lembang Observatory, 1928) The solar motion is assumed as 19 7 km /sec towards R A 270°, N Decl 30° 28′ (1900) This is taken out of the stellar motions, which are therefore absolute as being referred to the mean of the stars in the neighbourhood of the sun But the general motion of these stars round the galactic centre is not considered The parallaxes have been slightly modified where necessary, to make them accord with the adopted absolute magnitudes of the stars The proper motions in R A and Declination are then reduced to km /sec and combined with the radial velocities The resultant velocities are tabulated and the Right Ascension and Declination of the points to which they are directed The catalogue contains a number of stars of abnormally high velocity, as these have naturally attracted the special attention of observers

Work of the Naval Observatory, Washington — Volume 12 of the publications of, this Observatory is mainly occupied with equatorial observations of various objects, there are series of observations of the satellites of Mars and Saturn, and discussions of them for the improvement of their orbit elements Numerous comets and minor planets were observed, their positions are given from 1908 to 1926 The photoheliographic observations of sunspots extend from January 1917 to the end of 1927

The determination by wireless signals of the difference of longitude between Washington and San Diego, California, which was made in the autumn of 1926, as part of the international series of longitude determinations, is described in detail The observatory also controlled the sending of the wireless signals from Annapolis and Bellevue, near Washington, and made arrangements for those sent from Honolulu Small transit instruments were used, they were placed in the open air The transits were all made by the travelling wire method, this practically eliminates personal equation, so that interchange of observers is not necessary The amount of this equation was, however, determined by personal equation machines, and applied to the results of each observer The resulting difference of longitude between Washington and Paris is 5 hr 17 min 36 665 sec with a probable error of only 0 002 sec, it is 0 013 sec greater than the value obtained in 1913–14, also by wireless, but receiving the signals by ear None of the determinations in the series has a greater error than 0 003 sec, it will be remembered that in pre wireless days the difference between the English and French determinations of the longitude Paris Greenwich went into the first decimal

Spectroscopic Study of ξ Ursae Majoris —Mr Louis Berman investigates this system in *Publ Ast Soc Pacific* for February The star is a well known visual binary with a period of 60 years, and both the components are spectroscopic binaries The brighter component has the long period (for spectroscopic binaries) of 669 18 days, that of the fainter star is determined by Mr Berman as 3 9805 days Only one spectrum is visible, so the ratio of masses cannot be determined The eccentricity of the orbit is very small, and it has been treated as circular, $a \sin i$ is equal to 275,860 km The parallax 0 131″ is derived from the combination of the radial velocities of the components A, B This is in good accord with the value 0 123″ adopted from direct measures It is noted that the stars A B will be so close to each other until about 1940, that it will be impossible to obtain separate spectrograms of the two components, Mr Berman therefore considers this a suitable time to summarise our knowledge of this interesting system The spectroscopic observations determine which of the two possible positions of the plane of the visual orbit is the correct one

Research Items

Dental Morphology of Prehistoric Guam.—A collection of crania obtained by Dr J C Thompson and Mr H G Hornbostel in 1922 from Guam, one of the Mariana Islands in Micronesia, and now in the Bernice P Bishop Museum of Honolulu, has been examined by Dr R W Leigh, who publishes his results in vol 11, No 3, of the Museum's *Memoirs*. The crania are of pre Spanish or early post Spanish origin and belong to a homogeneous group which was probably inbred. The ancient Chamorros, as the inhabitants are called, lived exclusively on the fauna and flora of the island, a fact of importance in relation to the pathology of the teeth. Early navigators said they did not eat meat of any kind, though they had fowls and kept doves in captivity. Nor were they cannibals. They chewed betel but did not make use of fermented beverages. The teeth are well formed, the average dental index being 42 6, the group tending to the mesodont. Five per cent evidence slight developmental disturbance. Ethnic deformation was practised to a limited extent by filing on the facial surface of the six superior anterior teeth. Staining the teeth orange to black was customary. Owing to betel chewing there was a permanent discoloration of the enamel and a predisposition to degeneration of the investing dental tissues. The lime used produced enormous accretions on the teeth. Owing to the habit of chewing and the soft character of the food, there was a high incidence of periodontoclasia, the chronic destructive degeneration of the investing tissues of the teeth which eventuates in exfoliation. This was the major cause of the loss of teeth in later life but no person deceased before thirty years of age had lost any teeth; 18 per cent showed dental caries.

Destruction of Rats by Red-Squill Powders.—An ideal poison for rats must be effective, safe to use, and cheap. The ordinary rat poisons (strychnine, arsenic, phosphorus, and barium carbonate) are dangerous not only to domestic and wild animals, but also to human beings, and the U S Department of Agriculture has carried through tests with powders made from squill (*Urginea maritima*) (U S Dept Agr, *Tech Bull*, No 134). The results confirm E G Boulenger's work at the London Zoo, and the advice given in the British Ministry of Agriculture and Fisheries leaflet on the destruction of rats. It was found that red squill powder is toxic to rats, while white squill is not. Cats, dogs, chickens and pigeons are not seriously harmed by squill powders, since food so poisoned is either refused or, if eaten, is promptly vomited. Powders prepared by directly drying unfermented, sliced red squill bulbs in an oven at 80° C are usually more toxic than those prepared in any other way, the lethal dose being about 250 milligrams per kilogram of body weight for white rats, and rather less for wild brown rats. Variation in toxicity makes it desirable that squill powders should be tested before being marketed, and adjusted to a standard, 10 grams of 10 per cent squill bait to kill a minimum of 1 kilogram of rat.

Blood of the Eel.—Mr Nobuyuki Kawamoto contributes two papers to the fourth number of vol 4 of the *Science Reports of the Tôhoku Imperial University* (Fourth Series (Biology), Sendai, Japan, December 1929. "Physiological Studies on the Eel I The Seasonal Variation of the Blood Constituents II The Influence of Temperature and of the Relative Volumes of the Red Corpuscles and Plasma upon the Hæmoglobin Dissociation Curve"). In both researches the common eel, *Anguilla japonica*, was used. It was found that the relative volume, number of corpuscles, viscosity, and iron content increase as soon as hibernation begins and decrease as it approaches its end, but, on the other hand, the non protein nitrogen is much less at that time and increases in summer with the rise of temperature and period of growth. In the second paper it is shown that the hydrogen ion concentration of the blood was constant during 43 days of starvation. The oxygen capacity is directly proportional to the relative volume of red corpuscles, the volume varying much in the eel. Less oxygen is taken up by the blood when the temperature becomes higher, thus agreeing with previous work on other animals. The author concludes from the greater amount of heat produced during chemical reaction between oxygen and hæmoglobin that the blood of the eel possesses greater affinity for oxygen than that of the frog or man.

Differentiation of Sex.—In a summary article on the differentiation of sex in vertebrates, Dr Rogers Brambell (*Sci Progress*, April 1930) begins by accepting the sex chromosomes as a primary mechanism of sex determination firmly established, and then goes on to point out that while they are normally the decisive factors, yet other equally potent factors are at work. The fact that in *Drosophila* super males and super females as well as intersexes are produced when there is a lack of balance between the number of X chromosomes and the number of sets of autosomes shows that the latter play their part in determining sex. By crossing different geographical races of the gypsy moth (*Lymantria dispar*) Goldschmidt has obtained intersexes which led finally to the hypothesis that the Mendelian sex factors are quantitative, that racial variations occur in them, and that a time factor in their expression during development is also involved. It has long been known that the sex ratios of frogs in some localities are abnormal, and subsequent research has shown that some males develop testes directly, while in others they arise from transformed ovaries. The frequency of these two types of males differs in various localities. Witschi has shown by crossing hermaphrodites that the male frog is heterogametic (XY), and it appears that the indirect form of development depends upon a delay in the time at which the male determining stimulus becomes effective. Environmental factors as well as the time element, also play a part. Intersexes in pigs, the inheritance of which has been studied, and of the histology of which Brambell describes a case, again involves a time factor as well as quantitative sex differences, the ovotestes of pigs being accounted for by the abnormally late appearance of the male determining stimulus.

Development of *Callichthys*.—Miss Frances M Ballantyne in a paper entitled "Notes on the Development of *Callichthys littoralis*" (*Trans Roy Soc Edinburgh*, vol 56, part 2 (No 18), 1930), describes in detail the embryonic development of this very interesting South American siluroid. An unusually complete series of eggs and embryos collected by Dr G S Carter on his expedition to the Gran Chaco was available for this study. *Callichthys* makes a nest of leaves, and the eggs are carefully guarded by both male and female until the tadpole-like young are hatched. The process of segmentation is like *Salmo*. The embryo is far advanced when it emerges from the egg. Gill breathing is helped by the intestine, the caudal and dorsal fins probably taking part, especially in the early stages when they are very

vascular In development it resembles the Dipnoi in certain points, in others it is like *Polypterus* In many ways it is a typical teleost The paper is very well illustrated by clear diagrams in the text and by plates representing the various embryonic stages with reconstruction of the chondrocranium

Chromosome Linkage in *Œnothera* —An important paper on meiosis in *Œnothera* has been published by Mr D G Catcheside (*Trans Roy Soc Edinb*, vol 56, No 19), who has made a study of *Œ pycnocarpa*, *Œ nutans* ($2n=14$) and a triploid mutation of *pycnocarpa* He shows that in all three the chromosomes are arranged end to end in a closed ring Ishikawa, in a study of embryo sacs and fertilisation, found a case of dispermy in a hybrid between *Œ pycnocarpa* and *Œ nutans*, and the triploid *pycnocarpa* (with 21 chromosomes) is regarded as probably arising in this way, through the union of two male nuclei with the egg nucleus The fact that its chromosomes are in a closed ring of 21 is opposed to the hypothesis of parasynapsis in *Œnothera* On the heterotypic spindle in the triploid the chromosomes take up the zigzag arrangement characteristic of *Œnothera*, but always with irregularities Later, they separate usually 10 11, thus confirming an early account of Gates for triploid Œnotheras In the triploid, one of the three sets of chromosomes must be present in duplicate, and yet there are no free pairs of chromosomes This appears to upset the hypothesis that ring formation is contingent upon a heterozygous condition of the chromosome complement Catcheside supports the view that chromosome linkage is inherited as a genetic character determined by one or more genetic factors He shows that this hypothesis is in accord with the numerous cases of linkage thus far described

Proteolysis in Plants —Botanists will welcome warmly a brief restatement of his experimental investigations of the proteases of plants and of his conclusions therefrom, which Prof S H Vines has been moved to prepare (London Macmillan and Co, Ltd, 1930) as the result of making acquaintance with the rather different views on protein digestion by enzymes that have been advanced of recent years by Prof Willstätter and his collaborators In these later papers the different behaviour of different plant extracts to the protein substrate has been traced to the different activation in the different solutions of the same enzyme system, so that in one case it may attack fibrin, in another peptone, whilst the production of amino acids, such as tryptophane, during digestion was attributed to the decomposition of peptides by a peptidase Vines, on the other hand, thought that he had given good experimental grounds for the separation from some plant extracts of two enzyme systems, a peptase attacking proteins such as fibrin and an ereptase attacking peptone, producing from it amino-acids including tryptophane Vines restates succinctly the experimental grounds which led him to the conclusion, the paper is a very clear summary of his series of papers in a difficult field and is of value as putting the two alternative points of view clearly in contrast

Cretaceous Mollusca of South Africa —The species of *Trigonia*, which were so numerous and widely distributed in Mesozoic times, were divided by Agassiz into eight sections, to which three others have been added by later workers Following the present tendency to divide large genera into smaller groups, Dr E C N van Hoepen (*Palæont Navors Nas Mus Bloemfontein*, 1, 1, 1929) has proposed nine new genera for the species of *Trigonia* found in the chalk of Zululand Further and prolonged study of the species in other formations and countries is needed before the phylogenetic significance of these genera can be regarded as established J V L Rennie, in a paper on the Cretaceous fossils from Angola (*Ann S African Mus*, 28, 1, 1929), describes a number of new lamellibranchs and gasteropods from the Albian and Senonian, and points out the close relationship of the Senonian forms to those found in Pondoland and Zululand In another memoir the same author (*ibid* 28, 159, 1930) enlarges our knowledge of the molluscan fauna of the Senonian of Pondoland

Rotary Oil-Well Drilling Plant —The rotary system of drilling oil wells is now so well known and so securely established in practically all the oilfields of the world, that it would seem almost superfluous to describe other than revolutionary features But the last year or two has witnessed some of the most striking engineering feats in oilfield development that are on record, more particularly in connexion with deep holes, carried actually to depths of nearly 10,000 feet Since the rotary system of drilling has been responsible for such achievements, it is only natural that the recent modifications and developments of this time honoured plant should receive notice, and in Mr Neils Matheson's paper, read before the Institution of Petroleum Technologists on April 8, he did full justice to the means by which such results have been achieved The author described some of the latest types of drilling machinery designed to procure both deep and straight holes, the latter of almost equal importance to the former from a geological point of view Among the alterations noted are the increase of the size of the drilling rig to 136 feet (100 feet was considered quite a fair average only a few years ago), increase in derrick floor space to 26 feet, and replacement of standard 'band' and 'calf wheels' by secondary 'draw works' In other directions an important advance is made by replacing cast iron by 'electric steel', that is, cast iron made from 30 100 per cent steel scrap, and generally strengthening all materials employed both in plant and superstructure Labour saving devices are lavishly introduced and the problem of safety of the drillers—often conspicuously neglected in extra American oilfields—has received expert attention The evolution of the rotary oil-well drilling plant clearly has not come to a standstill, and as the demand for accurate rather than speedy drilling is increased, so we may expect a correspondingly high standard in design and efficiency of this extremely adaptable means of producing petroleum

High Voltage Electrometer —In the issue of the *Physikalische Zeitschrift* for April 1, Prof T Leodor Wulf of the College of Falkenburg describes a new filament electrometer which can be used for the measurement of high voltages About 2 cm of Wollaston wire is mounted vertically about 0 2 cm in front of a vertical strip of metal and the wire is kept stretched by quartz springs at its ends The strip and wire are mounted in a metal case from which they are insulated by a sulphur plug A metal sphere 6 cm in diameter projects into the case and its centre may be placed at any point on a perpendicular to the strip through the centre of the filament When the voltage to be measured is applied to the sphere, the filament is charged by induction and is attracted towards the sphere The motion of the centre of the wire is dead beat and is observed through a microscope from the side When the filament and strip are connected to the case, the instrument will measure up to 50,000 volts When filament and strip are insulated from the case and the voltage is applied

directly to them, the instrument will read down to 1 volt The instrument can be arranged for photographic reproduction of the motion of the filament, and several photographs are given in the paper

A Simple Transmission Dynamometer—In *Engineering* for May 16, Messrs E Giffon and C M White describe a new form of transmission dynamometer which has been in use for the last six months in the Engineering Laboratory of King's College, London Dynamometers for the measurement of the power consumption of any machine are generally of the torsion meter type, depending for their action upon the twisting of a shaft Such apparatus has to be delicate, needs careful handling, and requires considerable space The dynamometer described was designed to overcome these disadvantages, and tests of the instrument show that it is robust, fool proof, compact, and accurate In this apparatus power is transmitted by a spur wheel on the driving shaft to a spur wheel on a lay shaft This lay shaft also carries a sprocket wheel over which runs a chain, driving a sprocket wheel on this driven shaft The gear is enclosed in an aluminium case carrying ball bearings, and an extension of this case forms the torque arm, on the extremity of which weights can be placed Designed to transmit 10 h p at 2000 r p m, the dynamometer was tested by a comparison with a friction brake of the band type, and the results are given by a series of curves included in the article, which also gives illustrations of the apparatus

Direction Finding by Radio—Mr R H Barfield read a paper on April 2 to the Institution of Electrical Engineers (Wireless Section) on recent developments of direction finding apparatus This paper describes the results obtained when carrying out part of the programme of work mapped out by the Radio Research Board It is well known that direction finding apparatus of the closed loop type determines only the horizontal magnetic field of the radio waves To get over this difficulty, Adcock devised a receiving system of spaced vertical aerials This system, modified so as to produce a balanced effect, has been tested over a long period It was calibrated by means of a transmitter attached to a kite which sent waves at a known downcoming angle and with known polarisation The results prove that the flatness of the minima obtained with direction finding apparatus at distances exceeding twenty miles was undoubtedly due to downcoming waves Direction finding is possible on a wave length of 24 metres up to a distance of 70 miles in the daytime and 30 miles at night in the summer season Up to a distance of 20 miles the bearings are sharp and accurate to within 2° provided a good open site is found A site which is clear of obstables to a hundred yards in all directions would be very suitable At distances greater than 20 miles the minima are not nearly so sharply defined At greater distances than 500 miles, the Adcock system gives indications of bearings within about 5°, but the loop direction finder is practically useless The former system is much less affected by errors due to downcoming waves At close ranges where the downcoming radiation is weak, the loop direction finder is to be preferred as it is more compact, robust, and portable

The Decomposition of Nitrogen Pentoxide—The rate of decomposition of nitrogen pentoxide has recently been the subject of a number of investigations and the results are somewhat divergent In the April number of the *Journal of the American Chemical Society* there are two papers by Eyring and Daniels in which the rate of decomposition in inert and in chemically active solvents, respectively, is discussed on the basis of new experiments In the inert solvents the decomposition was found to be strictly unimolecular, and the small differences in velocity caused by a change of concentration (from 0 1 to 1 8 molar) or of solvent, are thought to preclude the possibility that the reaction is complicated by traces of catalysts The value of $1/2s$, where s is given by the equation $k = se^{-E/RT}$, is thought to represent, to a first approximation, the time taken for two atoms or groups at a valency bond to separate after activation, that is, the natural vibration period in the valency bond which is to break It is predicted that s will approach an approximate constant in nearly all unimolecular reactions In the case of chemically active solvents (nitric acid, propylene chloride, carbon disulphide, acetone, iodine) the results are specific and their interpretation is difficult, although solvation appears to play some part

Fabrics Research We have received the second report of the Fabrics Co ordinating Research Committee (Department of Scientific and Industrial Research, London H M Stationery Office, 1930, 5s net) which contains detailed reports on the fire proofing of fabrics, the action of sunlight on cotton, the waterproofness of 'porous' waterproof fabrics, the tensile test of fabrics, and the deterioration of fabrics by micro organisms The first report was published in 1925 The introduction to the report, written by the chairman of the committee, Dr R H Pickard, gives a useful summary of the contents of the volume, from which it is evident that research work of great thoroughness and value has been carried out The individual sections contain many tables and curves, and full bibliographies That on fire proofing, in particular, is of very wide interest, and is probably the best guide on the subject in existence Important results were obtained with borax and boric acid mixtures The mixture was found to be much more effective than either substance separately In the section on the effect of sunlight on cotton, use was made of the known fact that cotton after oxidation yields solutions in cuprammonium possessing a lower viscosity than similar solutions of the original fibre The action of sunlight in the presence of air is probably an oxidation process similar to that due to chlorine All the reports have important practical bearings, and the volume is one which will prove valuable in many aspects

Thermal Data on Organic Compounds—The April number of the *Journal of the American Chemical Society* contains a paper by Huffman, Parkes, and Daniels, giving the results of experiments on the specific heats and latent heats of fusion of a number of aromatic hydrocarbons The entropies have in some cases been calculated from these data, and found to agree with the equation $S_{298} = 25\ 0 + 7\ 7n - 4\ 5r + 19\ 5p$, where n is the total number of carbon atoms outside the benzene ring, p the number of phenyl groups in the compound, and r the number of methyl branches attached on the main aliphatic chain of the molecule A similar equation had been found to hold for liquid paraffins $S_{298} = 25\ 0 + 7\ 7n - 4\ 5r$, where n is the number of carbon atoms in the molecule and r the number of methyl branches on the side chain The free energies are also calculated, and ortho, meta, and para-isomers are considered to have practically identical free energies of formation The free energy of hydrogenation of benzene to form cyclohexane was calculated in two different ways, the results being in agreement The work was undertaken at the instance of the American Petroleum Institute

South-Eastern Union of Scientific Societies

CONGRESS AT PORTSMOUTH

THE thirty fifth annual Congress of the South Eastern Union was held at Portsmouth on May 28–31, at the invitation of the Lord Mayor and the City Corporation, the Portsmouth Literary and Philosophical Society, and the Portsmouth Geological and Archæological Society, with Mr O G S Crawford in the presidential chair in succession to Sir Arthur Keith

The meetings were held in the Municipal College and in the Guildhall, where the city plate were exhibited and explained by Mr J Hutt, the Chief Librarian In the Congress museum, held in the room of the Portsmouth Gas Company, many local objects were shown, the most striking being the prehistoric relics exhumed by Col J H Cooke from burials on the Portsdown Ridgeway, notably amongst them being a fine flint dagger of Solutré, a type found with the bones of a bronze age warrior of great stature An unusually interesting perambulation of Old Portsmouth was conducted by Mr R Pook, who had prepared a booklet for the occasion

The president, who is the well known Archæology Officer of the Ordnance Survey and the editor and founder of *Antiquity*, took as the title of his address, "What is Archæology?" He finds that few really realise what archæology is, and many papers written on the subject are really history, but there is a period of about a thousand years after Caesar's invasion in which the two overlap Anthropology, being the study of man, may deal with both history and archæology There is history of which but for the archæologist we should never have heard Such is, for example, the Minoan civilisation of Crete and although we have a dim reflection in the Iliad and the Odyssey of an early civilisation, we should have known but little of it but for the discoveries of Schlieman Archæology is a method of reconstructing the past, so far as man is concerned in it, and it replaces or supplements history Archæology is a hobby, but the student of it does not always do the actual digging as he often has to give lectures in order to raise the money for his work Mr Crawford emphasised the point that the æsthetic preserver of ancient structures must exercise moderation in his desire, since all that is ancient is not always beautiful and worth preserving Age and beauty are not necessarily associated The march of progress cannot be withstood, and the love of old things because they are old is in practice an attitude impossible to maintain We must adapt ourselves to modern developments The practical policy is to endeavour to preserve certain large areas of uncontaminated countryside as national playgrounds, so that in days to come our descendants may know what England once looked like A few uninhabited tracts so preserved would amply compensate for the loss of a few ruins or antiquities, the preservation of which may be found to be impossible

In field work Mr Crawford finds Great Britain supreme, whilst in the new science of air archæology it is not only supreme it stands alone An eloquent plea was made for the accurate naming of specimens, and also for the placing in a local museum of isolated finds that are often lost through being retained in private hands When Mr Crawford was excavating in the Sudan, one of his best workmen was a retired cannibal He had a lively imagination, but it was grounded in the hard school of life and fact He would have been an active if unconventional fellow of the Society of Antiquaries It is none too easy to reconstruct the conditions of prehistoric society, and almost impossible without some experience of a kindred society now functioning Prehistoric man's attitude to life was a severely practical one, he was fundamentally lazy, and he never did things that he would consider useless to himself The older archæologists were obsessed with the idea that ancient man was always at warfare, and forgot that the quest for food came first The struggle for existence was a real one, and warfare as a means in the struggle would have been useless unless there were loot to be got The face of England is a palimpsest The pattern in which it is laid out is the result of a long process of evolution The old patterns have to be traced under the new We are only now beginning to realise what immense possibilities underlie the latest development of archæology, that of air photography

In the Archæological Section a paper by Prof L S Palmer revealed some striking correlations between the pre history of Hampshire and Africa Like other travellers, Prof Palmer was struck by the consistency of the evolutionary forms of the flint artefacts with those that have been established in European countries and found that Hampshire was no exception Much attention was given to the Raised Beach terraces and the Coombe Rock overlying them in the coastal plain extending from southern Hampshire eastward into Sussex, and, following a paper by Col J H Cooke, excursions to view these formations *in situ* were carried out Near Westbourne Common a gravel pit revealed a series of pipes eating into an extensive mass of pounded and reconstructed chalk which here represents the Coombe Rock It is hoped that the Raised Beach will eventually be found below it M L'Abbe Breuil was a distinguished visitor amongst the party In the Coombe Rock of Emsworth Woods many split pebbles of distinct Blackheath Pebble Bed type were found, with the usual jasper like colour and with the pounded surface markings How they came here remains a problem

In the Botanical Section Col Wolley Dod's "Experiences of a Field Botanist" proved extremely interesting, and the report of the work of the Section showed that considerable progress has been made in the botanical survey of Sussex, which was commenced at Hastings in 1927 under the ægis of Dr A B Rendle Ashdown Forest is now particularly under examination, and a beginning has been made of the western area

In the Zoological Section Mr John F Marshall gave an account of the important work that is being done at the Mosquito Control Institute established by him at Hayling Island, and revealed to many this little known organisation of a great national service A record of intensive research work was given by Miss G F Selwood in her paper on "Fauna Changes in a Bog at Bembridge"

In the Regional Survey Section Mr D Halton Thompson gave an account of the sources of the water-supply of Portsmouth, and showed that most of the water came from the folded chalk, and little from the syncline in which the older Eocene beds lie north of Portsdown Mr G E Hutchings showed "Some Applications of Regional Survey in Education", and Mr A Farquharson gave the results of "A Regional Survey of Chichester"

Geologists and botanists concluded their visit to Portsmouth with an excursion to Whitecliffe Bay, Isle of Wight, where both branches of parties found much to record in the tertiary clays, sands, and limestones of that interesting spot

Members of the Congress attended a reception given by the Lord Mayor in the spacious Guildhall, and received every assistance and welcome from their hosts the municipal authorities

Leeds Meeting of the Institution of Gas Engineers

THE Institution of Gas Engineers met in Leeds for its annual meeting on June 2–6, under the presidency of Mr C S Shapley, manager of the Leeds Gas Department Several of the papers dealt with questions of actuality in the world of carbonisation

Mr E G Stewart examined the "Functions of Coke Ovens" in a paper of great interest in view of the recent issue of the report of the Area Gas Supply Committee His analysis revealed that only about four British gas undertakings are large enough to consider the installation of such plant, although a group of smaller undertakings might do so The coke ovens should rationally be attached to iron and steel works, which need the gas as fuel If that were generally the case, there would be no coke oven gas to spare As gas making plant, the coke oven is not superior to the modern vertical retort, which is more flexible The development of coking plants increases the pressure on the coke market, which will be intensified if the gas works purchase spare gas This points to the need for an understanding between the two industries for the marketing of both main and by products

The need for greater freedom in constructing the tariffs for the sale of gas was emphasised so that differential prices might be charged according to the incidence of the load Indeed the freedom to rationalise the charging for gas was advanced on all sides as an essential preliminary to rationalising the supply of industrial gaseous fuel

Dr E W Smith summarised the experience gained in the process of dehydrating coal gas before distribution This is a notable innovation introduced into practice by a British firm in 1925 By washing the gas with a strong solution of calcium chloride (glycerine has also been proposed) about two thirds of the water normally present in coal gas is removed The principal advantage is that the dew point of the gas is so far reduced that liquid water is never deposited in the mains and consequently corrosion of mains and meter etc, is almost entirely prevented Stoppages due to water and ice are avoided in winter, and many other advantages accrue, so that plants for the purpose are being erected with great rapidity and the practice is being adopted in foreign works

Mr F Prentice described three years' experience with a waterless gasholder, of which a few already exist in Great Britain The first was erected about fifteen years ago in Germany, where these holders are now numerous—indeed they are probably the most characteristic feature of the landscape in the Ruhr valley The normal gasholder consists of a bell floating in water, but these consist essentially of a vertical cylinder closed by a piston, which rises and falls as the volume of gas in the holder changes The piston is made gas tight either by a tar seal or a grease joint at its periphery where sliding contact is made with the walls Hailed at first as a piece of crazy engineering foredoomed to failure, a few years have falsified practically all of the prophecies, and many more will be seen in the future The Ipswich holder, which is 202 ft high, is only a small one and the large examples are undoubtedly wonderful engineering constructions

A paper by Mr C F Broadhead of Melbourne dealt with the production of a new road binder—bitural The paper has a bearing on the problem of current importance to all carbonising industries There is an over production of tar, with consequent difficulty in marketing in the face of mineral road making materials bitumen and oil pitch It is said that the tar from modern vertical retorts is not so good a road making material as the old tar Mr Broadhead attributes this to the large proportion of unsaturated hydrocarbons in vertical retort tar, and proposes to polymerise these by an oxidation in the presence of an accelerator which induces condensation of the unsaturated hydrocarbons with phenols to form larger molecular aggregations The tar is substantially altered in chemical character, and is said to have given satisfactory results in Australia as a road making material

The paper by Messrs W H Hoffert and G Claxton on benzole recovery in gasworks practice discussed the important question as to whether it is worth while to remove benzole from town's gas for use as motor spirit It has generally been assumed that it was not, and relatively little is so obtained The view is being challenged as the result of faulty costing and the gas works will probably become much more prominent in this direction The refining of benzole involves a loss of good fuel which has long been recognised as a challenge to the inventive The authors detailed their method of adding to the crude spirit suitable anti oxidant inhibitors to prevent the formation of objectionable gums which result from the polymerisation of unsaturated hydrocarbons essentially an oxidation process This is an interesting piece of chemistry which promises to be of great practical importance to the motor spirit industry

Dr Margaret Fishenden's paper was a collation of methods for handling heat transmission calculations In particular she gave the results of the application of the principle of similarity to correlate the results of measurements of convection, showing that the observations of different workers could be closely harmonised in this way

Prof J W Cobb gave an account of the relations between the Institution of Gas Engineers and the University of Leeds extending back to 1906 The Institution lent encouragement to the establishment of a Fuel Department at the outset, and in 1910 endowed the chair in memory of the late Sir George Livesey Since that time there has been close co operation in the prosecution of investigations bearing on the problems of the industry This is one of the earliest examples of co operative industrial research in Great Britain, and the paper collated a large range of subjects which have been covered since that time On the teaching side, it was stated that for years the demand for suitable graduates has been in excess of the men coming forward H J H

Visitation of the Royal Observatory, Greenwich

THE annual visitation of the Observatory took place on June 7 The Astronomer Royal presented his report, which deals with the work of the Observatory during the year ended on May 10 The usual fundamental meridian work was carried on with the transit circle, the sun having been observed on 150 days, and the moon on 104 days The excess of the moon's longitude over its tabular value was 5 2″, the excess has been diminishing since 1924 by nearly ⅓″ per annum the corresponding excess for the sun, which was 1 7″ in 1926, has now fallen to 1 6″ The observation of stars in the zone 32° to 64° of declination will be completed this year The next star catalogue will cover the zones 0° to 24°, and 64° to 90°,

it is not now considered necessary to observe many stars fainter than magnitude 8 on the meridian, the positions of fainter stars are obtainable by photography with lenses of wide angle

Observations with the Cookson floating zenith telescope now cover a period of nineteen years, which is the period of the great lunar nutation term Dr J Jackson is discussing the observations, to deduce a new value for the coefficient of this term, it appears that the adopted value 9 210″ will not be altered by more than 0 002″ The Gerrish drive, installed last year on the 28 inch equatorial, has worked very well 300 binaries were observed during the year, of which 56 were separated by less than ½″

The determination of stellar parallaxes by photography with the Thompson equatorial has proceeded at an accelerated pace, 1508 parallax plates having been taken, and 651 plates measured

The determination of the 'colour temperatures' of stars has been continued with the 30 inch reflector The observation of 24 stars selected as standards has been completed, these are now available as a base to which other stars can be referred The absolute temperatures of the standards are now being found by comparison with an arc lamp, which in turn will be compared with a gas filled lamp already calibrated at Utrecht

The astrographic equatorial, which had been sent to Siam for the solar eclipse, was remounted in July Some renewals in the bearings and accessories were satisfactorily carried out by Messrs Grubb, Parsons and Co The Greenwich astrographic zone, decl 64° to 90°, is being re photographed for the determination of proper motions by comparison with the earlier plates, the motions of 14,500 stars between 64° and 72° have now been published

The sun was photographed on 270 days at Greenwich, plates taken at the Cape and Kodaikanal will render the record complete The spot activity is definitely on the wane, there were, however, large spots in November and December A spectrohelioscope has been lent to the Observatory by the Mount Wilson Observatory, it has been mounted in the south attic of the new building A survey of the sun's disc in H_α light is made daily, when weather permits Special attention is paid to the radial velocities of dark markings near sunspots

Spot numbers for the whole disc, and for the central zone, are supplied regularly to Zurich for incorporation in the bulletin that is issued there under the auspices of the I A U

The mean temperature of the year was 51 0°, which is 1 5° above the 75 year average, the extreme values were 90 5° on Aug 31, and 25 4° on Mar 20, both dates are unusually late for the extreme readings The rainfall was 25 43 inches, which is 1 19 in above the average The winter was a stormy one, and the mean daily air movement, 289 miles, is 5 miles above the average The highest daily value was 847 miles on Dec 7, the highest hourly value 62 miles on Jan 12, which also had the greatest pressure, 38 lb per sq ft

The following are the mean values of the magnetic elements for 1929, obtained at Abinger, Decl 12° 35 8′ W, Hor Force 0 18555 Vert Force 0 42918 Dip 66° 37 2′ It is noted in the report that a more precise instrument for determining the vertical force and dip was lent by the National Physical Laboratory, it revealed a small systematic error in the values given by the dip inductor, the error was 0 00010 in Vert Force, 0 3′ in Dip

The performance of the Shortt clocks continues to be satisfactory, in the sidereal clock No 3 an invar bob was substituted for the type metal one, the latter contained lead, and a certain amount of settling appears to have gone on, causing an increase of losing rate This increase still goes on with the new bob, but at only half the former rate

Rhythmic time signals from the Observatory are distributed by the wireless station at Rugby at 10 h and 18 h These, and the signals sent to the Post Office and the B B C, are controlled by the clock Shortt No 16

The following are the mean amounts by which the time signals from other stations are late on Greenwich Paris 0 044 sec Nauen 0 006 sec Annapolis (near Washington) 0 007 sec Bordeaux 0 035 sec These are after corrections for lag and time of travel have been applied

A C D CROMMELIN

An Early Letter from Darwin to Owen

THE letter printed below was bought at Sotheby's in March of this year for the Fitzwilliam Museum, Cambridge, by some friends of that institution It was written rather more than two months after Darwin's return in the *Beagle* The fossil vertebrates referred to in the letter were sent to the Royal College of Surgeons Darwin wrote to Owen, who was five years his senior, as a young man addressing a more experienced and older colleague later the two became friends and Owen visited Down in 1848 Twelve years later, in a letter to de Quatrefages, Darwin wrote "I have been atrociously abused by my religious countrymen, but as I live an independent life in the country, it does not in the least hurt me in any way, except indeed when the abuse comes from an old friend like Professor Owen, who abuses me and then advances the doctrine that all birds are probably descended from one parent" ("More Letters of Charles Darwin", vol 1, p 202) Reference is made to Darwin's attitude towards Owen in a note printed at the head of a letter to Hugh Falconer (1863) on page 226 of vol 2 of "More Letters"

Darwin settled at Cambridge on Dec 10, 1836 he was at first a guest in the home of the Henslows, and later went into lodgings at a house in Fitzwilliam Street, on which a tablet has been fixed The letter was written as from Christ's College, though he was presumably not actually in residence there

A C S

Decemb 19th (1836)

My dear Sir,

I have just written and will send it the same time with this, a letter to Sir Ant Carlisle I have done exactly as you recommended me I thought myself compelled to fix on the British Museum in preference to that of Paris because I was carried on board a King's Ship, and the public collection of the country certainly has claims on me If the collection had been made entirely at my own expense, that is on board a Merchant vessel, then I should not have hesitated in making a different choice I quite agree with you that the British Museum ought to make returns when it has the power I suppose you could not venture to propose another set for Paris Their value would be so much more in that collection than in the British Museum I ought to make up my mind to give my own set to Paris, but I confess I should be grieved to lose my trophies I should feel like a knight who had lost his armorial bearings If the Council should not choose to go to the expense necessary for making all the casts, it was suggested to me here, that the

College might pay the price of forming the casts, and the public bodies purchase the models, but I think you will agree with me, that if this can be avoided, it will be better With respect to great head of the Rodent, I certainly feel inclined to run the risk of taking a cast, because the models will be more generally useful, even in case the head itself should be injured or destroyed But I am sure after the kind and effectual manner with which you have entered on this affair I cannot do better than follow your advice I, at one time, began to think that the fossil bones would be as troublesome to me and as of little service as some other branches of my collection are likely to be But now I look back to the trouble I took in procuring them with great satisfaction I do assure you I feel very grateful to you for having given me such good assistance I have scarcely begun to unpack my cases, in the course of a week I shall have every thing open, and I already know of one very large bone (of a Mastodon ??) which I will forward to the College When separating the animals in spirits, I will put by any that I think will interest you And it will be a great pleasure to me if I chance to possess anything which will be of use to you in your number less investigations

Believe me, my dear Sir,

Your very truly obliged
CHAS DARWIN

Christ Coll

Lincoln's Inn Fields

Biochemical Studies of Spike Disease of Sandal

MR M SREENIVASAYA and Mr B N Sastri have continued their very detailed investigations into the spike disease of sandal (*Santalum album* L), and their latest results are to be found in the *Journal of the Indian Institute of Science*, vol 12A, Part 17, pp 233 to 252 (1929) Leaf juice from a sandal tree infected with the spike disease hydrolyses more soluble starch than does the corresponding healthy juice This is due to a higher concentration of the enzyme and to the presence of activators such as phosphates and amino acids The *p*H of spiked leaves is lower than that of healthy leaves, and approaches the optimum for diastatic activity More potato starch is, however, liquefied by the healthy leaf extract than by the diseased extract for equal weights of sugar produced, thus suggesting a qualitative difference between the two diastase extracts It should be remembered that Dr L C Coleman found that there was lower diastatic activity in spiked leaves than in healthy leaves, and therefore the results here reported might be interpreted as showing that the diastase content of diseased tissue fluctuates within the same limits as does that of healthy tissue

The chemical composition of leaf and stem tissue fluids has also been investigated The spike diseased leaf contains more nitrogen, maltose, and reducing sugars and less ash (particularly calcium) than the healthy leaf The stem fluids of spike diseased trees are richer in nitrogen, phosphorus, and calcium than those of healthy plants, and there is a steep gradient of calcium concentration between the stem and leaves

The seasonal variations in composition of healthy and partially spiked leaves of the sandal tree have been studied by Mr A V Varadaraja Iyengar (*Jour Ind Inst Sci*, vol 12A, Part 20, pp 295 305) Season was found to affect the chemical composition of the leaves of both healthy and spiked plants in the same manner The following relative differences were observable in all seasons—the diseased sap had less dissolved matter, less osmotic pressure, a greater electrical conductivity, more moisture, ash, and nitrogen contents, less calcium, and was more acid than healthy sap

These detailed studies on sandal spike from the Indian Institute of Science have considerable significance, for it has recently been shown by Mr M J Narasimhan (*Phytopathology*, 18, pp 815 817, 1928) that inclusion bodies similar to those which characterise certain virus diseases are present in leaf tissues of spiked plants This, along with the work of Dr L C Coleman on transmission, suggests that the malady is caused by a virus We have thus a mine of detailed information on the chemistry of a diseased host which we can use in the elucidation of the problem of the nature of a plant virus

University and Educational Intelligence

ABERYSTWYTH —Dr C D Forde formerly of the Department of Geography, University College London, has been appointed to succeed Prof H J Fleure in the chair of geography and anthropology at the University College of Wales, Aberystwyth Dr Forde has just returned from the University of California, where he held a fellowship from the Commonwealth Fund, and received the degree of doctor of philosophy for his researches among the Hopi Pueblo Indians of North Arizona

CAMBRIDGE —The following have been appointed members of the Committee for the Natural Sciences Tripos for the year 1930–31 Prof A Hutchinson (chairman), Prof T M Lowry, Mr H Thirkill Dr W H Mills Mr A Wood, Mr E Cunningham, Mr F T Brooks, Mr T C Nicholas, Mr J T Saunders Dr Dean, Sir Frederick Gowland Hopkins, Prof J Barcroft

The General Board recommends that a University demonstratorship in pharmacology be established in the Faculty of Medicine

Mr Stanley Baldwin was installed as Chancellor of the University on June 5 and in the course of his address announced that the gift from the Rockefeller Foundation had been made available through the completion of the collection of a sum which was made a condition of the grant The total sum required for the University Library and for research work was £1,179,000 The Rockefeller Foundation had promised £700,000 conditional on the balance being raised by the end of 1931 This balance has now been raised

Honorary degrees were conferred by Mr Baldwin after his installation on the following, among others Prof A Einstein, of Berlin, Prof Max Planck, of Berlin, Sir John Rose Bradford, president of the Royal College of Physicians, and Sir James Colquhoun Irvine, principal and vice chancellor of the University of St Andrews

LIVERPOOL —Among the honorary degrees conferred on June 5 were the following Doctor of Laws, Mr R L Mond, honorary secretary to the Davy-Faraday Research Laboratory of the Royal Institution, Doctor of Science, Prof G Barger, professor of chemistry in relation to medicine in the University of Edinburgh

LONDON —Applications are invited for the Graham Scholarship in Pathology, value £300 per annum, in the first instance for two years, founded under the

will of the late Dr Charles Graham to enable "a young man to continue his pathological researches and at the same time to secure his services to the School of Advanced Medical Studies connected with University College Hospital as a Teacher under the direction of the Professor of Pathology"

The latest date for the receipt of applications is June 17 They should be sent to the Principal, University of London, South Kensington, S W 7

OXFORD —The question of the destiny of the Radcliffe Observatory site and buildings has now come officially before the University in the form of a decree in Congregation By this it is proposed to accept the offer of Sir William Morris, the purchaser of the site from the Radcliffe Trustees, to vest the whole of the property in the hands of a body of trustees, in order that it may be used for the benefit of the Radcliffe Infirmary and the Medical School of the University The terms of the trust provide that the old observatory building shall be used for the purpose of medical teaching and research, and that the observer's house and garden shall be used as a residence for the director of the institute of research to be constituted in accordance with these terms

The report issued by the Curators of the Botanic Garden includes a list of noteworthy plants lately received, and mentions improvements in the labelling of trees shrubs, and plants

The Herbert Spencer Lecture, delivered by Sir Peter Chalmers Mitchell, was a vigorous defence of materialistic monism which, he said, so far from being discredited as a theory by recent advances in physical science, stands now in an even stronger position than in Spencer's day Not one of the forms of what is called vitalism can, in his opinion, stand the test of critical examination Progress in science must be achieved, as of old, by the way of experiment and observation

In a lecture recently delivered in Oxford, Miss Caton Thompson gave an interesting account of her exploration of the Great Zimbabwe and of other ruins in Rhodesia She dwelt upon the fact that no evidence of any kind exists to suggest that these remains are of other than Bantu origin, or that they owe any thing to outside influence The stratigraphical evidence which is now available from many sites in Rhodesia all points in the direction of Bantu as against Arab, Phœnician, or any other kind of foreign activity

---

THE New York correspondent of the *Times* states that Mr Louis Bamberger, the retired head of Bamberger and Co, Newark, New Jersey, and his sister, Mrs Felix Fuld, have given £1,000,000 for the establishment in Newark or the vicinity of an institute for advanced study, exclusively for post graduate work and scientific research

AT a meeting at the Mansion House, London, on June 2, the Lord Mayor presiding, it was announced that a contract had been signed for the purchase of a freehold site in Bloomsbury for 'London House', the proposed hall of residence in London for British male students of European origin from the Dominions and Colonies and from Great Britain The object of the meeting was to launch an appeal for a fund of £250,000 to be administered by the Dominion Students' Hall Trust, for which an influential council of governors has been appointed, with Mr F C Goodenough, of Barclay's Bank, as chairman Towards this fund £130,000 has already been contributed The appeal was supported from the platform by Mr L S Amery, Mr H A L Fisher, Mr Stanley Bruce, Sir James Parr, Sir William Clark, Sir Drummond Chaplin, Lord Moynihan, and Mr F C Goodenough Special reference was made to the post graduate medical school to be established at Hammersmith 'London House', while closely associated with the University of London, will be an independent institution and the governing body includes representatives of the University, the Royal Colleges of Surgeons and Physicians, and other professional institutions The Corporation of the City of London and the Rhodes Trustees have each made a donation of £5000 to the fund The Lord Mayor read a letter from the Prime Minister strongly supporting the appeal "London House", he said, "appeals to common sense, to the spirit of hospitality, to the imagination Let us look ahead and see the young men of our race coming to London with their vigour and freshness of outlook, intermingling with us and each other, sharing in our heritage of learning and experience and tradition, and returning so equipped to wherever British energy and enterprise have set their homes"

THE Committee of Award for the Commonwealth Fund Fellowships has made appointments to 26 fellowships tenable by British graduates in American universities for the two years beginning September next, including the following Mr R W Adams (Belfast) to Massachusetts Institute of Technology, in electrical engineering, Mr J T Calvert (Oxford) to the Massachusetts Institute of Technology, in sanitary engineering, Miss I G M Campbell (St Andrews) to Cornell University, in organic chemistry, Miss R L Cohen (Cambridge) to Stanford University, in agricultural economics, Mr A G Emslie (Aberdeen) to Cornell University, in physics, Mr H Fisher (London) to the Massachusetts Institute of Technology, in civil engineering, Mr G V B Herford (Oxford and London) to the University of Minnesota, in zoology, Dr D W Hill (Bristol and Liverpool) to the University of Illinois, in biochemistry, Mr F L Hudson (Manchester) to the University of California in physical chemistry, Dr J Irving (St Andrews and Cambridge) to Harvard University, in geology, Mr T H Kelly (Birmingham) to Columbia University, in economics, Mr J E MacColl (Oxford) to the University of Chicago, in economics, Mr J E Meade (Oxford) to Stanford University, in economics, Mr A K Nuttall (Cambridge) to Stanford University, in electrical engineering, Dr R W B Pearse (London) to the California Institute of Technology, in physics, Mr R W Revans (London and Cambridge) to the University of Michigan, in physics, Mr W J Sartain (Cambridge) to Yale University, in economics, Mr W A Sinclair (Edinburgh and Oxford) to Harvard University, in philosophy, Mr S Steele (Cambridge) to Johns Hopkins University, in aero engineering, Mr William Wild (Leeds) to the University of California, in physical chemistry The following have been appointed to fellowships tenable by candidates from the British Dominions Mr N S Bayliss (Melbourne and Oxford) to the University of California, in chemistry, Mr W G K Duncan (Sydney and London) to the University of Chicago, in sociology, Mr P J Hogan (Dublin and London) to Iowa State University, in civil engineering, Mr S J Pretorius (Stellenbosch and London) to Cornell University, in economic statistics The following have been appointed to fellowships tenable by candidates holding appointments in Government service overseas Dr C M Tattam, of the Geological Survey of Nigeria, Mr C Vigne, of the Forestry Department, Gold Coast Colony, Capt R D Waghorn, of the Indian State Railways

Historic Natural Events

June 15, 1818 Avalanche Flood—An avalanche from the front of the glacier of Lépenaz blocked the outlet of the Lake Glière, raising its level 25 feet When the dam broke a mass of water estimated as one hundred million cubic feet in volume flooded the valley of Doron of Champigny, carrying away all the bridges but one

June 15, 1829 Hailstorm—At Cazorla, in the south east of Spain, hailstones fell in the form of blocks of ice, some of which had a circumference of 20 in and weighed as much as 4½ lb Great damage was done, houses being literally crushed beneath the bombardment of ice

June 15, 1896 Japanese Earthquake Sea-waves — A great earthquake occurred off the north eastern coast of Japan, its epicentre being 150 miles from land at a depth of 4000 fathoms (4½ miles) near the foot of the western slope of the Tuscaroora Deep The shock was slightly felt on land, but after a lapse of 21 minutes great sea waves, more than 60 feet in height, swept over the coast and caused the loss of 27,000 lives The sea waves were recorded at Honolulu (3591 miles) and Sausalito (San Francisco Bay, 4787 miles)

June 15, 1914 Severe Thunderstorm over Paris — On June 15, 1914, a severe thunderstorm occurred over Paris During the storm 2 1 in (54 mm) of rain fell, 1 6 in (41 mm) within twenty five minutes On only one other occasion has this been equalled The heavy rain caused the subsidence of several streets

June 16, 1819 Indian Earthquake—The great earthquake of Kutch, in the delta of the Indus, disturbed an area of more than 3 million sq miles A large tract of land, 2000 sq miles in area, subsided, and the sea, flowing in by the eastern mouth of the Indus, submerged the village of Sindree and converted the tract into a lagoon A short distance to the north, the previously level plain was raised as an elevated mound, 50 miles long and about 10 feet in height, running east and west or parallel to the line of subsidence

June 17, 1815 Thunderstorms—There were heavy thunderstorms in Belgium on June 17, which made the roads difficult for traffic As a result the movements of the French army, which were timed for the early morning of June 18, were delayed until nearly noon This loss of time may have affected the course of the battle of Waterloo

June 18, 1764 Thunderstorm in London—During a violent thunderstorm the steeples of St Bride's in London and the church at South Weald in Essex were both struck by lightning and much damaged At St Bride's the metal spindle carrying the vane was fixed into a stone, and the greatest damage was done at this junction, the stone being shattered into small pieces H M S *Ramillies*, lying at Chatham, was split and torn to pieces by the lightning at about the same time It is noted that the preceding weather had been very warm and dry, and that the damage was done before the rain began to fall The storm is of interest for the discussion which it provoked at the Royal Society, and because it helped to bring about the use of lightning conductors in Great Britain

June 18, 1907 Waterspout—A phenomenon variously described as a 'cloudburst' or 'waterspout' occurred near Blanchland on the eastern edge of the Durham Moors A dense column, shaped like two cones joined at their apices, approached very rapidly, with a noise like the engine of a heavy motor-car Near the village it burst, and an immense volume of water fell from it, flooding the whole countryside, while heavy rain and hail added to the damage Large stone walls were broken up and their contents scattered over the fields, while the roads were seriously damaged and in places entirely destroyed Eight sheep were killed by lightning, while others were washed away and drowned

June 19, 1566 Floods in Europe From June 19 onwards for a whole month there was serious flooding by the Rhine There were also great floods in the Danube, Drau, and Save In England, after a very rainy spring, the summer was dry and the autumn almost rainless

Societies and Academies

LONDON

Linnean Society, May 1—E B Worthington Vertical movements of fresh water macroplankton The changes in vertical distribution of Crustacea were examined over periods of twenty four hours or more in the Victoria Nyanza and in Lake Lucerne by means of a vertically hauled closing plankton net The movements of the plankton were traced from hour to hour and correlated with the amount of light and other physical conditions In L Lucerne, most species start their descent at dawn, and reach their lowest level (50 60 metres) before the sun attains its zenith Then a slow upward movement starts, accelerates at dusk, and continues for two or three hours after complete darkness There is a difference between the behaviour of young and old individuals of certain species The organisms appear to be under the influence of two forces (1) a negative geotropism, acting persistently from below and causing them to congregate in the upper layers, and (2) a negative heliotropism, acting intermittently from above and causing those species which are susceptible to light to descend during the day Most species are filter feeders, dependent on the nanno plankton, which is most abundant in the upper layers, it is suggested, therefore, that hunger is the ulterior reason why they should seek the upper layers—G P Bidder On the attitude of a Hexactinellid at the bottom of the sea, as compared with that assumed in museum jars and monographs Glass sponges have never been seen in the great depths which form their natural habitat, they are known only from specimens torn up from the bottom of the ocean The dermal tissue of sponges is sensitive to the movement of water over its surface If we assume that in growing sponges growth is more rapid on the side against which the current impinges, we can explain the anomalies of spoon like and fan like forms in the same species of Choniid or Axinellid sponges in which cup like forms are found, the cup like form showing a compassing tide and the fan a constant current A similar reaction in a sponge of fixedly tubular shape would cause the side of the tube towards the current to grow longer than the sheltered side, so that the sponge would bend until the axis of the tube lay down stream and all sides were acted upon equally—M Burton Glass sponges The scientific history of sponges can be resolved into three phases (1) prior to 1842, when opinion was divided whether they were plant or animal, (2) from 1842 until recent years, when they were regarded as animals, but their position was doubtful, (3), 1929, marked by Dr Bidder's proposal to revive the idea of treating them as a sub kingdom, the Parazoa This sub kingdom he divided into two phyla, the Nuda and the Gelatinosa, the former to include the Hexactinellida only, the latter the rest of the sponges This recognition of the great gulf between the Hexactinellida and other sponges, and between sponges and the rest of the animal kingdom, counteracts the tendency

to make too close a comparison between the Hexactinellida and other sponges, and it also lays stress on the undesirability of seeking to homologise the structure of sponges with that of the Metazoa

CAMBRIDGE

Philosophical Society, May 19 —Dr P A M Dirac (1) On the annihilation of electrons and protons On the basis of the relativity wave equation for the electron, a calculation is made of the probability per unit time of an electron jumping into a state of negative kinetic energy and emitting the surplus energy in the form of two light quanta If we assume that nearly all the negative energy states are occupied by electrons and that an unoccupied one is a proton, this probability gives the rate at which electrons and protons annihilate one another The calculated rate is much too large to be in agreement with observation —(2) Note on exchange phenomena in the Thomas atom The equations of the self consistent field with inclusion of exchange effects may be expressed in terms of a single total electron density function If we approximate to this density by considering it as a classical function of commuting co ordinates and momenta, we get the equations of the Thomas atom with an extra term representing the exchange effects

EDINBURGH

Royal Society, May 16 —**Georg Weigner** Base exchange The difficulties experienced by Way and other early investigators in explaining the mechanism of exchange processes are gradually being overcome by intensive study of reactions in colloid systems Cation exchange properties are attributed to micelles consisting of an ultramicron, an inner layer of anions, and an outer swarm of cations, only the ions of the outer swarm are exchangeable, and the extent of the reaction depends upon their hydration, valency, and the forces binding them to the inner layer For example, magnesium, on account of its greater hydration, is absorbed less readily than the other alkaline earths, but it is not so easily displaced, because it forms less soluble compounds with the hydroxyl ions of the inner layer The ultramicron of clays and permutites may contain silicic acid and aluminium hydroxide, within certain limits, the greater the proportion of the former the greater the cation exchange That is because there is a greater dissociation of cations from the silicic anions than from the hydroxyl ions attached to the aluminium Ionic exchange determines the potential and coagulation of the particles

PARIS

Academy of Sciences, April 28 —**Ernest Esclangon** The determination of the position and of the elements of a planet or distant comet Application to the Lowell celestial body —**Gabriel Bertrand and Mme M Rosenblatt** The proportion of potassium and sodium contained in plants which grow in brackish water or on the sea-coast The analysis of sixteen species of plants is given All the plants contained both potassium and sodium, with a general predominance, sometimes considerable, of potassium It is only in plants adapted to media rich in common salt that the ratio K/Na falls below unity —**A Th Schloesing and Désiré Leroux** The solvent action of carbonic acid with respect to phosphoric acid in agricultural soils —**André Blondel** Falls of electromotive force in triphase apparatus feeding unsymmetrical circuits —**Henri Villat and Maurice Roy** Concerning the problem of Saint Venant for the slit cylinder Reply to some remarks by A Mesnager —**S Finikoff** *W* congruences having along corresponding radii the same linear complex operator.—**Georges Bouligand** Certain classes of surface of three dimensional Euclidian space —**Henri Cartan** The exceptional values of a meromorph function in the whole plane —**Elie Cartan** The third fundamental theorem of Lie —**Marcel Dufour** The astigmatism of the pencil refracted by a spherical diopter —**P Swings** The resonance groups of the diatomic vapour of sulphur —**Maurice Piettre** The function of the non electrolytes in the stability of biological media If electrolytes play an important part in the equilibrium of organic liquids, this rôle is restrained within certain limits Lipides have a very remarkable influence the physico chemical mechanism of which is still unexplained —**M Paić** Study of the system HgO SO_3 H_2O A combination of analytical and X ray methods —**A Travers and Avenet** The estimation of the total cyanogen in effluents from coke ovens The essential point is treatment of the well-cooled solution with sodium peroxide before acidifying and distilling off the hydrocyanic acid —**Sébastien Sabetay** The optically active acidylhydrazides and their use for the separation into optical isomers of the racemic aldehydes and ketones —**J Bougault and Mlle L Popovici** The reduction of the semicarbazones and thiosemicarbazones of the α ketonic acids and of the sulphoxytriazines —**Raymond Chevallier** The permanent magnetisation of the Feroe basalts —**H L Parker** The polyembryonic development of *Macrocentrus gifuensis* —**Raymond Hovasse** Some new data on the cochineal insect, *Marchalina hellenica* —**Ugo Lumbroso** New researches on the etiology of trachoma The study of a germ, met with in Tunis, in its relations with the *Bacterium granulosum* of Noguchi

GENEVA

Society of Physics and Natural History, Mar 6 —**R Wavre** The force which, at earlier periods, tended to draw a continent to the equator The author gives an extremely simple formula for calculating the intensity of the force which causes a floating body, boat, iceberg, or continent to increase its distance from the pole This force is proportional to the square of the velocity with which the earth turns round its axis This velocity has been reduced in the course of geological epochs owing to the phenomenon of tides The force in question was much greater then than now —**G Tiercy** A formula giving the value of the colour index of a star This deals with the question of obtaining a new approximation of the solution of the problem, retaining terms the influence of which has hitherto been neglected in the calculation —**E Rod** Tables of the coefficients of the instrumental errors, in Mayer's formula, for the latitude of Geneva These new tables have been worked out for declinations from $-31°$ to $+80°$ The values are given for every degree from $-31°$ to $+30°$, every 30′ from $+30°$ to $+35°$, every 20′ from $+35°$ to $+69°$, and every 10′ from $+69°$ to $+80°$

Mar 20 —**L Duparc** An anorthose trachyte from Gambeila (Abyssinia) The author has collected in small volcanic cones a rock of a particular type, formed almost exclusively of microlites of anorthose The rock is very rich in alkali (nearly 15 per cent) —**J Briquet** The glochide trichomes of Helminthia The author shows that, contrary to that which has been recently proved for the glochide emergence of Crupina, the multiseries glochides of Helminthia are of purely epidermal origin, without vascular elements, and their hoods are formed uniquely by the curvature of the apical cells of the foot This puts the glochidate hairs, from the functional point of view, in relation with a mode of zoochore dissemination —**E Pittard** The coronal angle in the skulls of Bushmen, Hottentots, and Griquas The author has measured a series of skulls sent to the anthropological laboratory of the University of Geneva by the Cape Town Museum The values obtained compared with those of the

cephalic index indicate certain differences between the Hottentots and the Griquas —R Wavre The planetary stratifications The author gives a method for recognising whether a given family of surfaces can represent the stratification of a star in rotation This method dispenses with the calculation of the potential As a particular case, he arrives very simply at the theorems of Volterra and Dive on the impossibility of ellipsoidal stratifications —P Balavoine The luminosity of some colouring matters in ultra violet light If wool or silk dyed with auramine is submitted to ultra violet light, there is produced a strong yellow luminosity resembling phosphorescence Fluorescine and its derivatives present the same phenomena, but with less intensity

May 8 —J Carl Some observations on the relief of southern India In the course of a journey made during the winter of 1926–27, having for its principal object studies of the fauna, the author also made observations on the relief of the country He distinguishes three erosion cycles clearly visible on large scale maps His interpretations are in agreement with the evolution of relief of the island of Ceylon, described by F D Adams (*Canadian Journal of Research*, 1929)

PRAGUE

Czech (Bohemian) Academy of Sciences and Arts (Second class, Natural Science and Medicine), Feb 7 —L Borovansky Morphological changes in rats effected by strenuous work —J Charvat, A Gjurič and E Sedláčková The protein preparatory reflection —V Jarnik Some remarks on the Hausdorff measure —V Kladivo The determination of the relative intensity of gravity in Brno and Potsdam respectively —J Basta The mechanical theory of the solidification and hardening of cements and concrete It is concluded from experimental investigations that the chief physico chemical laws determine the hardening of concrete and rational formulæ are derived for practical use —R Nováček Biological factors in the formation of dolomites —F Wald Principles of the theory of chemical operations

Mar 14 —V Kladivo The determination of the relative intensity of gravity in Brno and Vienna respectively —R Brdička and M Pavlik Automatic registration of extinction curves of absorption spectra An apparatus has been constructed which makes possible the photography of continuous absorption spectra in solutions by using a Baly tube in which the thickness of the solution layer is automatically diminished logarithmically with time, whilst the dark slide is shifted with constant speed A complete characteristic extinction curve is thus obtained in about 20 min —J Hybl The heat of evaporation of liquids The constants a, b, c were evaluated for twelve polyatomic liquids in the following expression for the heat of evaporation $a(T_{cr} - T) - b(T_{cr} - T)^2 + c(T_{cr} - T)^3$, where T_{cr} is the critical temperature —A Vančura The function of factors outside the kidney in the origin of kidney and heart œdema —P Sillinger The vegetation of the limestone hills of Tematínské Kopce (Western Slovakia) On the dolomites of this small group near Pišt'any the pennonic associations predominate, though the Carpathian element is not absent Exhaustive description of all plant communities of this region is given —K Domin *Draba fladnizensis* Wulf, a new species for Czechoslovakia This alpine species was found in the Tatra of Biela. The author gives an analysis of the plant associations on the localities of this Draba, which represent an interesting glacial relic —F Prantl Revision of Czech Devonian Fenestellidæ —J Sobotka Generalisation of cyclographic and stereographic projection

Recruitment in the Colonial Services

A SHORT time ago a Committee was appointed under the chairmanship of Sir Warren Fisher to report on the System of Appointment in the Colonial Office and the Colonial Services its report which has been recently issued merits careful consideration In an opening section attention is directed to the extraordinary diversity of the territories administered by the Colonial Office covering an area of two million square miles practically all within the tropics with a population of nearly fifty millions Although often alluded to as the Colonial Service in effect there is no such thing as the Colonial Secretary has to deal with the affairs of more than fifty distinct governments ruling territories in size from as large as Central Europe down to remote island groups conditions of life material equipment and economic factors being entirely dissimilar

Recruitment to fill the government posts in these diverse governments has developed in the past in a haphazard fashion under varying conditions depending more on the ideas of a local governor for the time being than upon those of the authorities in Great Britain Since the Armistice matters have greatly improved and the number of posts has increased In 1909 the appointments made by the Colonial Office numbered 657 in 1929 they rose to 1076 and this in spite of the fact that many classes of appointments which were normally filled from Great Britain twenty years ago are now staffed locally But the Committee insists on the fact that this is not merely a matter of numbers Modern conditions demand also a generally higher standard of personal educational and professional qualifications and in addition the employment of men with scientific and special attainments of a kind not previously to be found in the Colonial Service It is the Committee s recommendations on this latter part of the problem which it is proposed to consider here

It will be necessary however to summarise briefly the excellent exposition given in the Report of the present system of appointment to the various Colonial Services (it is not proposed to dwell on the internal administration of the Office at home) and the recommendations made for its improvement Apart from local recruitment the selection of home candidates for employment in the Colonial Services is made in four chief ways (*a*) The Civil Service Commissioners in London hold periodical examinations for the selection of candidates for Eastern Cadetships (administrative appointments in Ceylon,

Malaya, Hong-Kong, etc), for the Ceylon police and for the post and telegraph services in Nigeria and the Gold Coast, (b) the Crown Agents to the Colonies select and appoint on behalf of Government candidates for technical posts, such as railways, public works, and so on, the selected men serving for a term of years, (c) the Private Secretary (Appointments) to the Secretary of State, aided by a strong staff, selects and recommends to the Secretary of State outside candidates for a first appointment in the Services, (d) other departments of the Home Government are asked, where necessary, to select from their staffs men with the desired qualifications to fill certain appointments overseas These departments are the War Office, Post Office, Customs and Education, Home Office and Air Ministry

It will be evident from the above résumé how varied have been the methods which have grown up with the object of securing quantity, quality, and variety of the staff required to carry on the great area administered from the Colonial Office

We are here concerned with the great variety of appointments, by far the larger number annually, the selection for which is carried out, and, as the Committee emphatically emphasises, admirably carried out, by the Private Secretary (Appointments) and his staff The Private Secretary and staff have always been able to obtain the advice and assistance of specialist advisers, both from the Colonial Office and the universities and from men of eminence in various professions, and lastly from senior Colonial officials on leave or recently retired The Committee places on record that the selection of candidates has at all times been undertaken with the greatest care and that the Colonial Governors have expressed entire approval of the type sent out The Committee is also at pains to show that the idea, which has prevailed in some quarters, that Oxford and Cambridge have been specially favoured in this selection is not borne out by facts The bulk of the appointments in administration have gone, for various demonstrable reasons, to these two universities, but London and the Scottish universities have provided the largest number of men for appointments in medicine and scientific departments, Edinburgh being specially mentioned as "the principal source" for forestry

Whilst fully acknowledging the successful manner in which the selection of candidates is carried out, the Committee considers it undesirable that it should continue to be performed by a staff of private secretaries to the Secretary of State It recommends that this staff should cease to be in the position of private secretaries and that the appointments branch should be incorporated as a permanent part of the Personnel Division of the Colonial Office In addition, it is recommended that a Colonial Service Appointment Branch, consisting of a chairman and two members nominated by the Civil Service Commissioners, should be set up as a standing independent branch for the final selection of candidates whose names are put forward by the appointments branch, and that the names of those selected be then submitted to the Secretary of State, on whose authority the appointments will be made It is also suggested that the promotions branch should be reorganised on a smaller scale and be a section of the Personnel Division There can be little doubt that these are excellent suggestions, and if put into effect they will greatly strengthen the hands both of selectors for first appointments and also of those dealing with that important question of promotion On the able recommendations of the Committee on the latter question space will not permit further digression but in the future interest of the Service they merit careful consideration

One other recommendation of the Committee requires mention before the scientific services are considered The question of the unification of the Colonial Service is discussed The Committee points to the hardships of officers on small cadres in the smaller dependencies, and admits all the objections which have been put forward—differences of salary, leave, pension, climate, customs and language of the people, and so forth, it recognises the reluctance of Governors and others to any change After a consideration of all the objections, the Committee remains convinced of the importance of unification and recommends that a single Colonial Service should be formed and that, within this larger whole, unified special services should be organised, such as agriculture, forests, medicine, education, and so forth As the Committee correctly points out, this issue is of the very first importance "Much of the information on which it rests cannot be present in the minds of Governors or their advisers overseas, since it relates particularly to questions of home recruitment and to the difficulties of individual Colonies"

The question of the technical and specialist research officers remains to be considered The Committee states that

"many of the officers appointed to scientific and technical services such as agriculture, forestry, veterinary, medical, and so forth, are qualified to undertake research work of a fundamental character, and some officers are appointed in the first instance

for the specific purpose of carrying out research work on urgent problems confronting a particular service In the ordinary course, however, an officer appointed to the agricultural service with special knowledge of plant diseases or insect pests, would rank for promotion in the higher grades in that service along with officers engaged in more general and less systematised duties, and would not necessarily confine himself to work of a specialised character throughout his service "

The statement that "many" of the officers appointed to the above services "are qualified to undertake research work of a fundamental character" would, for some of the services, scarcely be admitted at the universities Twenty per cent would probably be too high a percentage Experience has also shown that a young officer, on first appointment, should have a few years of executive work *before* being detailed for research This will prevent his making recommendations, when he takes up research, which the executive officer knows to be impracticable But this type of research officer, as the Committee points out, belongs to a definite service, will go up the grades of that service, will not necessarily confine himself to research all his service, and has a chance of securing the prizes of his own service His social position is also assured as a member of a service

The other type of research officer is perhaps of even greater importance—the whole time specialist As the Committee must have realised, this type has so far received scant attention His value is not called in question He is in demand The universities could say in how great demand They are aware that Government has now to compete in this market in some directions with the wide awake commercial people These specialist research officers are selected on the understanding that their whole service will be devoted to their particular line of research It is contemplated that their work will be of such a character that any results they may obtain will be applicable in many parts of the Colonial Empire Some of them may find it practicable to pursue their investigations in one particular research institution Others may find it necessary to conduct their researches in different parts of the Empire, attached either to a research station or to a scientific department In the normal course of things it is neither to be expected nor would it be desirable that their advancement should be conditioned by the occurrence of vacancies in the higher ranks of services other than their own. The Committee states that "it does not follow that such a service should be graded like other colonial services, for each individual in it must determine his own line of research in his particular sphere of work" In this connexion the Committee says

"In our opinion Research Officers should be encouraged by means of special inducements in the way of salaries and other terms of service to continue their long range investigations These terms should, in our opinion, be at least equal to those which they would be likely to obtain if they were prepared to abandon purely research work for more general duties"

Clearly there are considerations other than salaries to be taken into account in dealing with the research officers, and we should have preferred the Committee to have been more specific in its references to this class It would be disastrous for recruitment if the research officer were to remain 'no man's child', which would mean that he would not enjoy the social position which attaches to the services in the Empire circles overseas (and is of importance out there) The man may not care about this, but when he marries his wife will, and Government will lose a good man An example may be quoted Soon after the formation of the Agricultural and Forestry Research Institutes at Pusa and Dehra Dun, India, by Lord Curzon, a representative from each centre met by chance and discussed prospects In reply to some remark, the Pusa man ejaculated, 'Yes, your position is very different You belong to a Service We at Pusa do not" Dehra Dun was staffed from the Indian Forest Service The Pusa specialist returned home shortly afterwards and was a great loss That conversation took place more than twenty years ago!

A possible way out of this difficulty, it may be suggested, would appear to be to appoint each specialist research officer (for example, of the type serving in Malaya and Tanganyika) to one or other of the scientific or technical services (to which his investigations most nearly correlate) and then second him for research work on the understanding that his service would be spent on such work much as Royal Engineer and Military Medical officers are seconded for civil duty and remain seconded for the rest of their service High salaries, higher than the Colonial Office could afford to offer, will not tempt, or if tempted retain, the right stamp of man unless the social conditions of life are assimilated to those of the Services Incorporated in a Service, seconded with staff pay as specialised research officers, would, it is believed, remove the existing disabilities and secure in increasing numbers the type desired for this increasingly important work The Committee thus alludes to this work

"On the economic side we have to bring to bear the latest results of scientific research on the development of wealth, which is important, not only to the Colonies themselves but also to the Empire and the World Most of the greater problems of the Colonies to day are problems of Applied Science"

Possibly, however, the Committee wishes the research service to be a separate entity, under the general administrative control and supervision and responsible alone to an officer at the Colonial Office, linked through him with the various Imperial Bureaux which have recently been established, and through them with the British Dominions This is the underlying assumption in the various reports on colonial research to which the Committee refers, and particularly that of the sub-committee which reported to the Colonial Office Conference of 1927 on the possibilities of the creation of a Colonial Scientific and Research Service, available for the requirements of the whole Colonial Empire, in other words, the creation of an Imperial Service, financed out of an Imperial fund, to replace a number of water tight provincial services which have too long been dependent on individual Colonial governments, most of which have hitherto given little indication of their appreciation of the value of long range research

How Fire Became Known

Myths of the Origin of Fire an Essay By Sir James George Frazer Pp vii + 238 (London Macmillan and Co, Ltd, 1930) 12*s* 6*d* net

A NEW book by Sir James Frazer is assured of a cordial welcome, both on account of the exhaustive compilation of material which is rendered easily accessible to readers, and by reason of the charming literary style in which the collected data are placed on record and discussed The problems which are suggested by the mass of facts brought together and collated are without question intriguing In the present instance Sir James has set himself the task of collecting together for comparative study the various myths and legends which serve to explain to the primitive mind the way in which fire became known to mortals, and how, later, a knowledge was acquired of the means of producing fire at will Man, without doubt, was acquainted with and made use of fire, as kindled by natural processes, long prior to his discovery of the fact that it was possible to *make* fire by artificial means whenever occasion demanded Sir James even suggests a phase when man was "ignorant of the use or even of the existence of fire", and discusses the problem in terms of three successive phases, (1) the Fireless Age, (2) the Age of Fire Used, (3) the Age of Fire Kindled—phases which appear to be suggested by a study of the beliefs in regard to the origin of fire While the latter two phases are readily acceptable, as coming within the period of early human culture-development, it is less easy to imagine even the most primitive members of the genus *Homo* having been entirely unacquainted with fire as a phenomenon in Nature There is no evidence to prove that Nature did not cultivate the incendiary habit until man was already specialised as Man and had become differentiated from the rest of the animal kingdom His forerunners must already have experienced Nature kindled fire and must have learned to respect, or at any rate fear it It seems very unlikely that even proto man could have completely lacked such experiences, and it becomes difficult to credit a human phase involving complete ignorance of fire

In nearly all the myths of the origin of fire as an accessory to human culture, the supernatural plays an important part, and the pre scientific attempts of primitive minds to interpret the phenomenon of fire naturally do not show any inkling of its true nature In a strikingly large number of the legends, fire is reputed to have been stolen for man's use, usually from some supernal possessor, and, similarly, knowledge of the art of *making* fire has been very widely believed to have been obtained by trickery So wide spread among primitive peoples is this belief in the original theft of fire, that it appears highly probable that the Promethean myth of the ancient Greeks, with its closely similar record of the purloining of fire from Zeus, or from Hephæstus, was inherited as a traditional story handed down from a remote past, undergoing variation in detail to adapt it to local environmental and culture conditions It appears far more probable that this fire legend of Prometheus was a slightly modified descendant from an ancient and widely diffused folk tale, than that in it we see the prototype of a myth which spread from a centre of advanced culture and became disseminated among a vast number of heterogeneous and widely separated peoples of low culture

Prometheus, according to the legend, carried the fire which he had stolen ἐν κοίλῳ νάρθηκι, and, as Sir James says (p 195), the *narthex* "is commonly identified with the giant fennel " He expresses doubt as to Theodore Bent's suggestion that the *narthex* was a reed inside which the smouldering tinder was carried "to prevent its being blown out" ("Cyclades", p 365) The reason given for this

practice is questionable, since smouldering pith and other tinder substances burn more freely when blown upon, and it is probable that the protection would be against too rapid consumption of the tinder rather than against extinction of the spark. But there is some support for the theory that the *narthex* was a reed tube used to contain the tinder, since at the present day the custom obtains, in Manchuria, for example, of igniting a piece of pith and of carrying it smouldering in a tube of reed or bamboo. This at least gives some plausibility to the suggestion that the legendary Greek fire thief carried his ignited piece of fennel pith in a protecting sheath of reed. As a means of elucidating this academic point, it would be interesting to ascertain definitely the nature of the plant which is called *ναρθηκα* to this day by the inhabitants of Lesbos. Is it the giant fennel, or is it a reed, as stated by Bent?

In addition to the intrinsic interest of a nearly exhaustive *corpus* of myths detailing the varied ideas of various peoples all the world over, as to how the use and, later, the making of fire were discovered by man, there is the important bearing which the collation of such a mass of material has upon the wider ethnological problems. To the tracers of culture affinities and culture diffusion the data collected and presented in so masterly a manner, with the wealth of references to sources of information, will prove a valuable mine. Sir James Frazer has, indeed, by launching this new addition to his already powerful fleet of 'classics', increased materially the indebtedness of all those who study the problems of human culture.

HENRY BALFOUR.

Preparing Estimates for Ships

The Design of Merchant Ships and Cost Estimating: a Treatise on Ship Design and Cost Estimating, giving up to date Methods of arriving at Correct Proportions, Form and Power to attain Minimum Capital Cost with Maximum Service Efficiency. By Alexander Kari. Second edition enlarged. Pp. xiv + 307. (London: Crosby Lockwood and Son, 1930.) 36s. net.

THE designing, constructing, and fitting out of a ship may be compared with the planning, building, and furnishing of a great hotel which, when complete, must be ready in all respects for the reception of both guests and staff. In both cases there are somewhat similar preliminary investigations to be made and equally elaborate calculations as to size, accommodation, materials, and cost, while at every turn strict attention must be paid to official regulations. How elaborate these calculations are in the case of ships is well shown in this book of Mr. Kari's on "The Design of Merchant Ships and Cost Estimating."

Ships not only differ in size, form, and speed, but also there are many special types of vessels all of which demand separate consideration. Passenger vessels, cargo vessels, colliers, grain carriers, oil tankers, refrigerated ships, ice breakers, cable laying ships, dredgers, and tugs are examples of merchant ships built for special purposes, the designers of which must not only have a firm grasp of the principles underlying all naval construction but also a wide knowledge of the dimensions, performances, machinery, and fittings of vessels already on service. The collection of the data relating to the latter is one of the tasks of every draughtsman and shipbuilder, and the possession of such data is regarded as a valuable asset for the preparation of estimates. It is with this practical side of the subject that Mr. Kari has mainly dealt.

Commencing with a discussion of the choice of the type of hull to meet the shipowners' requirements, chapters are devoted to the determinations of a ship's dimensions, freeboard calculations, and to the general arrangements in cargo and passenger ships, the spacing of water tight bulkheads, and to the various regulations of the British, French, Norwegian, German, and Italian authorities. The general design of the ship having been determined, the detailed estimates of weight and costs have to be made, and in Chapters x. and xi. not only are the weight and cost of the steel structure dealt with but also a complete review is given of the hundred and one items found in every ship. The cost of materials varies with the locality and state of the markets; the cost of labour depends on the grades of workmen, their labour efficiency, and the general efficiency of management. Under the title "Wood and Outfit" are included the cement work used for preservation of certain parts of the hull, the wooden decks, floors, ceilings, hatch covers, gangways, cabins, fittings, mess rooms; iron fittings such as anchors, davits, bollards, ladders, gratings, staunchions, rails; the various systems of piping, the painting, rigging, canvas gear, boats, deck machinery, navigation instruments, steering gears, winches, the electric installation and insulation. Further chapters deal with the size and weight of propelling machinery, with resistance and screw propellers, and with service performances.

The text is accompanied by more than a hundred

tables of data, and a series of diagrams, curves, and sketches, the latter ranging from outline diagrams of types of ships to sketches of deck and cabin fittings. The book is one which will no doubt be found of use on many occasions and of value as a work of reference for everyday use.

Diatoms: Satis superque!

Notes on Diatoms: an Introduction to the Study of the Diatomaceæ. Compiled by Frederick Beatson Taylor. Pp. ii+269. (Bournemouth: The Compiler, 2a Montague Road, 1929.) 21s.

WHATEVER opinion may be held as to the general usefulness of such a book as the above, one pays homage to the industry and patience that went to its compilation. From Leeuwenhoek to De Toni, from 1703 to 1929, the author has ranged, collecting a mass of information that one piously hopes may be useful to the student of the group. Whether it assists in clearing up what Grunow described as "le chaos qui règne actuellement dans certains genres" is doubtful, and as an "Introduction to the Study of the Diatomaceæ" (which, by the way, is the title of Mills and Deby's book of 1893), it is much less useful than such a book as Hustedt's "Süsswasser-Diatomeen Deutschlands". Accompanying the book in a pocket at the end are five plates of illustrations of species, four being from outline drawings and one from photomicrographs, this last being by far the best of the plates.

The sixteen chapters contained in the book present the opinions, contradictory or unanimous as the case may be, of an army of authorities upon every phase of diatom life, many of the opinions being entirely obsolete and not a few grotesque. A loose sheet of corrigenda accompanies the volume, which, however, does not include all the corrections necessary; for example, the statement on p. 49 that Bailey dissolved valves of *Pinnularia* in *hydrochloric* acid. If the book is intended as a help to the beginner in the study of diatoms, the chapter on collecting and preparing diatom material might have been amplified and have included references to the excellent and practical directions for this work given in the books of Meister and Hustedt.

One cannot accept the statement made in Chap. iii., and repeated in Chap. viii., that the presence of diatoms in fresh water is an indication of its suitability for drinking purposes, and that a desmid flora should be regarded as a warning against doing so. I recently made a collection of diatoms from a farm-yard ditch that was largely contaminated with sewage, and the richest collection of diatoms I have ever made, both in species and individuals, came from a small pond the water of which no one would regard as potable. Whipple long ago gave examples of the fouling of water by a dense diatom population. On the other hand, desmids abound in lakes and reservoirs from which the water supplies of large towns are derived. Considerable space is devoted in the chapter on "Structure and Markings" to the controversial subject of 'resolution', but the beginner who reads the book as an introduction will probably be utterly lost amidst the contradictory opinions of the authorities quoted, many of which opinions are quite amateurish, and might well have been omitted in the interests of conciseness.

'Craticular' diatoms receive considerable attention from the compiler in this chapter. It is rather a cynical comment on the methods of some diatomists to find such forms elevated not only to specific rank but to generic rank also, as in the case of the genus *Craticula* constituted by Grunow. There can be little doubt that they are the result of a pathological condition. I have a slide containing numerous specimens of *Navicula cuspidata*, one individual of which shows the 'craticular' state in one hemisphere of the frustule, the other being quite normal. That the condition has nothing to do with changes in the salinity of the water, as was suggested by Marpmann, may be inferred from the fact that the species above named, which seems to be especially liable to the 'craticular' condition, is a fresh-water species.

Chap. xi., "The Species of Diatoms", wherein the compiler brings together the opinions of many authorities on the desirability of limiting the numbers of species, and reducing the number already in existence, will be read sympathetically by those engaged in taxonomical work on the group. Probably nowhere has the manufacture of species and varieties gone to such absurd lengths as in the Bacillariales, and unfortunately it still continues. Dimensional varieties, and even pathological forms, abound in the various text-books, and every new authority contributes his quota to the confusion.

In "The Literature of Diatoms", to which Chap. xii. is devoted, is brought together in chronological sequence titles of practically all the principal works on the Diatomaceæ, with the dates of their publication, and useful notes indicating the ground covered by the authors. No reference, however, could be found to "An Introduction

to the Study of the Diatomaceæ", by F W Mills and Julien Deby, published by Iliffe and Son in 1893, which contains a valuable bibliography of diatom literature up to that date When referring to Meister's "Die Kieselalgen der Schweiz", it is not made sufficiently clear that the work deals only with fresh-water species A list of monographs on various genera and books relating to the diatom flora of special areas adds to the usefulness of the chapter

A review of the genera of diatoms, with authors' names, and dates when the genera were established, is a chapter of the book that will prove of great service to historical students of the Diatomaceæ References are also given to the principal works in which the genera may be found No pains seem to have been spared to make this list as complete as possible, and an addendum to the chapter adds additional genera and references This chapter is probably the best and most useful in the book A good index is provided G T Harris

Our Bookshelf

Mathematical Geography By Prof A H Jameson and Prof M T M Ormsby Vol 2 *Simple Astronomical and Trigonometric Surveying, and the more Advanced Study of Map Projections* Pp viii + 160 (London Sir Isaac Pitman and Sons, Ltd, 1929) 6s net

The comment made in this journal on Volume 1 of this work was that it would be welcomed by geographers for its scope and clarity The second volume has now appeared, and continues the treatment of map projections more fully and completes the course which the authors set out to cover Vol 2 deals principally with the astronomical determination of position on the earth, more advanced surveying, and a progressive advanced treatment of map projections The influence of the spheroidal shape of the earth on map projections is also dealt with

The book is in general clearly written and, in spite of its more advanced character, easy to follow The illustrations are clear and suited to the requirements, although one may enter a protest against Fig 33 and the elaborate dual deductions which follow therefrom The section on photographic surveying, unfortunately, is only sufficient to indicate where a satisfactory treatment is to be obtained Surely such a modern development was well within the scope of the work, and was deserving of more adequate handling

Care has been taken in the preparation of the book—a feature evidenced by the freedom of the text from error The examples and exercises which are included in the work are an additional commendation This volume will be added to the list of useful books by all who are interested or concerned in this subject J Eling Coleclough

The Flood New Light on an Old Story By Harold Peake Pp x + 124 (London Kegan Paul and Co, Ltd, 1930) 5s net

Mr Peake's book on the Flood is an account, intended primarily for a popular audience, of the bearing of recent archæological investigation on the legend of an all destroying deluge This legend is world wide in its distribution, but it is best known in the version given in the Book of Genesis The author accepts the view that a common origin for the various legends is not probable, but the Hebrew version was most certainly derived from the Mesopotamian epic of Gilgamesh brought back to Palestine after the Captivity The discovery at both Ur and Kish of a stratum of clay of a thickness which could only be due to a considerable inundation has given reasonable ground for believing that the legend has here preserved a record of an historical event With this as the basis of his argument, Mr Peake expounds for the benefit of the public he has in view the wider question of the bearing of recent archæological research on the historicity of events once regarded as entirely mythical, but of which the record may now be regarded as enshrining an element of truth

Although Mr Peake's book is primarily intended to be of popular interest, scholars cannot afford to neglect it, for his account of the pre- and post diluvian culture of Mesopotamia is suggestive in its interpretation of the difficulties which at present offer puzzles for the archæologist Most ingenious of all, perhaps, and indeed a *vera causa*, is his suggestion that the discrepancies between the records and the archæological evidence relating to the early dynasties of Ur may have arisen from a misplacement of the tablets when the lists of the kings were copied

The Book of Electrical Wonders By Ellison Hawks Pp 316 + 41 plates (London, Bombay and Sydney George G Harrap and Co, Ltd, 1929) 7s 6d net

Electricity has so many applications, and it is so much in evidence everywhere, that it may be presumed that few of the rising generation of boys and girls are without some knowledge of batteries, dynamos, telephones, and vacuum tubes If the elementary principles are clearly explained, even the most complicated electrical machinery lends itself to popular exposition, and there is ample room for well written books such as that by Mr Hawks Within the space of some 300 pages he has been able to include a great deal of interesting matter regarding power stations, electric lighting, electric furnaces and welding, telephones, telegraphs, radio communication, X rays, photo telegraphy and television There are no fewer than 41 plates and 91 illustrations It is a book which will no doubt find its way into the hands of many boys, and it is essentially one to be included in the school library In the preface Mr Hawks says that Faraday's annual salary probably never exceeded £100 One is happy to think Faraday was paid more than that, and moreover, had he been so minded, he might have made a fortune

Letters to the Editor.

Science and Philosophy

THE leading article under this title in NATURE of June 7 is interesting not only in its exposition of the subject but also in marking a phase in the history of thought Throughout what is for the circumstances a fairly full discussion there is only one reference to biology, and this in the form of a hint that the fundamental ideas of that branch of science are in especial need of critical examination It is highly probable that in no such article written at the beginning of this century could the explicit reference to biology have been so slight both in substance and in tone The occasion indeed brings into sharp prominence the extent to which the biological sciences have, during the last thirty years, lost prestige in the intellectual world, and ceased to influence philosophic thought It is well that this fact, whether it ought to give rise to satisfaction or regret, should be clearly recognised Nevertheless, however complete may be its intellectual insignificance to day, the fact remains that in any attempted *rapprochement* between science and philosophy biology is still very much to be reckoned with, and not the less because during the late comparatively silent years it has been steadily adding to its store of knowledge, and especially in those of its branches that are specially relevant to the proposed work of reconciliation

A philosophy is an attempt to bring into harmony the verifiable truth of science and the intuitive truth of the mind That these two categories are, at whatever depth, identical is the assumption of the philosopher, it is also the assumption of the naive intellect, but the notorious effect of secular experience is to make the supposed identity less and less superficially obvious It was long thought that the two categories had a meeting place and common station in mathematics and that our intuitions of number and space did give us verifiable objective knowledge This has remained true of number because apparently internal experience of number is as good as external experience of it, that is to say, abstract number is indistinguishable from concrete number It cannot, however, any longer be accepted for space, for we now know that if the scale is large enough (and perhaps small enough) the intuitions we have formed on the strength of binocular vision and the so called stereognostic sense are not all verified by experience The developments in physics which are commonly supposed to have done so much for philosophy have thus, it would seem, incidentally taken away one of its time-honoured supports

It is, however, the developments in the biological sciences that appear to have done most to increase the severity of the philosopher's task, though the retreat of biology from its former position in the world of thought has tended to obscure this fact

In the reconciliation of verifiable and intuitive truth, the mind, if we may use a legal metaphor, is not only one of the parties to the action but also the judge The knowledge that the last thirty years have given us of the limitations and liability to error of the mind in what we may call its judicial capacity, is therefore highly relevant and certainly not less so than the advances in physics, which in relation to philosophy have attracted so much more attention That the wish is apt to be father to the thought, even in the highest and austerest activities of the mind, is no longer a mere proverbial tag but a scientific fact, and we now know that in appropriate circumstances desire can override all evidence The work of Pavlov, again, little as its implications for man have been followed out, and strangely ignored as it has been by the philosopher, contains matter that may well have to be reckoned with in estimating the validity of human judgment, especially perhaps in regard to our sense of causation

The biological conception of the mind as a natural product will have to be assimilated if philosophies in general are to lose those two characteristics which are so apt to discourage interest in them, first the tendency, however complete they may seem to their inventors, to prove intransmissible without gross modification, and secondly, the odd coincidence that after surveys of phenomena no matter how extensive and sublime, they so often but confirm the convictions and beliefs in which their inventors were bred

These are some of the considerations which make it seem probable that, in any successful *rapprochement* between science and philosophy, biology will have a more active part to play than merely to submit to the critical overhaul of its scientific concepts

Developmental Mechanics of Chicken and Duck Embryos

IT has recently proved possible to cultivate young chicken and duck embryos *in vitro*, using the 'watch glass technique' employed at the Strangeways Laboratory for the cultivation of embryonic organs Experiments using a somewhat similar technique were made in this laboratory two or three years ago by T S P Strangeways and D H Strangeways, but the work was given up after a few trials and the results never published The embryos can easily be kept alive for two or three days and differentiate nearly normally, although the rates both of differentiation and of growth are slower *in vitro* than *in vivo* I wish here to summarise some experiments which I have recently performed on this material full reports will be published in the near future

At the stage when the primitive streak is fully grown but the head process has not yet appeared, the blastoderm can be removed from the yolk and the endoderm and mesectoderm separated from each other So far the isolated endoderm has never given any signs of differentiating *in vitro*, but the mesectoderm will form neural folds, somites, and a notochord If the endoderm and mesectoderm are separated and then brought together again in such a way that their original longitudinal axes are approximately at right angles, it is found, in chick embryos of the above age, that the embryo develops in the direction of the ectodermal axis, and that the endoderm forms a foregut in the correct place as determined by the ectoderm However, in a similar series of experiments on considerably less developed duck embryos, in which the primitive streak was not fully grown, that structure, as it lengthened and grew forward, was bent round towards the anterior part of the endoderm in later stages the embryos became straight, lying in a direction midway between those of the ectoderm and endoderm. This result appears to indicate that both the layers have a polarity, and that under the conditions of these experiments, both layers play a part in the determination of the axial direction of the embryo

If two mesectoderms, from two chick embryos of

the primitive streak stage, are placed with their ventral (mesoderm) surfaces together and are cultivated in that position, it is found that the primitive streak of the lower mesectoderm induces neural folds in the upper mesectoderm, which thus comes to have two sets of folds, its own original set and the induced set Probably the induction is mutual, each mesectoderm acting on the other, but as the lower mesectoderm rapidly degenerates, perhaps for lack of oxygen, this cannot be determined with certainty If there is a considerable difference in the degree of development of the two mesectoderms, the younger appears unable to induce neural folds in the older In several cases, in which an older mesectoderm has induced neural folds in a younger mesectoderm, and in which the direction of the induced folds was at right angles to that of the younger primitive streak, the younger primitive streak has failed to develop, and only the induced neural folds are present in the upper mesoctoderm As in the amphibia, the organising power is not species specific, since a duck primitive streak has induced neural folds in chick tissue, and vice versa

Grafting experiments, in which pieces of primitive streak, cleared of endoderm, have been planted upside down between the endoderm and mesectoderm of a host embryo, have shown that the organising power can be manifested by such isolated pieces this result can be taken as fairly definitely proved for the anterior end of the primitive streak including the primitive pit, but it is not yet entirely certain for the posterior part isolated from the primitive pit Here, again, certain grafts between the duck and chick have been successful These grafting experiments also make it clear that a developing neural tube can induce the formation of somites from mesoderm which normally would not form such structures It is hoped to perform similar grafts in the near future using the endoderm underlying the primitive streak

The phenomena described in the last paragraph, in which the primitive streak is found to induce neural folds, that is, primitive streak derivatives, are perhaps more nearly comparable to the 'homoiogenetic induction' of medullary plate by medullary plate in Triton than to induction by the dorsal lip of the blastopore

The hypothesis that the organising capacity of the primitive streak is inherent to some extent along its whole length, which is suggested by the grafting experiments, is also supported by the fact that if any part of the primitive streak is removed, regeneration takes place and in many cases a perfect embryo results The more posterior the piece removed, the easier it is regenerated The head rudiment can also be regenerated, presumably under the control of the primitive streak In this case the regeneration is usually incomplete two half heads are first formed, one on each side of the hole made by the operation, and these later fuse more or less well in such cases, the two heart rudiments may be prevented from fusing and two beating hearts are developed, it is not yet certain how far regulation goes on in the half hearts, which are bent, and are mirror images of each other. In contrast to the regeneration of the head under the influence of the primitive streak, it is found that if the entire primitive streak is removed, including the primitive pit and Hensen's knot it is partially, and sometimes quite considerably, regenerated

A certain amount of work has been done showing that regenerative processes can take place at a considerably later stage thus if the eye-cup and lens are removed from a 15 somite embryo, a regenerated cup and lens are formed which are at least morphologically perfect

It will be seen that the developmental mechanics of the chick blastoderm are decidedly complicated Probably there are several regions capable of acting as organisers in Spemann's sense, and, notwithstanding Hoadley's demonstration (*Jour Exp Zool*, vols **42**, **43**, etc) that some self differentiation of parts of the blastoderm can be obtained from very early stages, it seems to be true that the blastoderm retains for a considerable time enough plasticity to be affected by such organising regions As yet little is known about the limits of this plasticity and not very much about the distribution and potentialities of the organisers, though in the latter case perhaps enough is known to suggest a comparison with the gradient of susceptibility to poisons found by Hyman (*Biol Bull*, vol 52) C H WADDINGTON

Researches on the X-Ray Spectrum of Sulphur

SOME results of an investigation of the effect of chemical constitution on the λ ray spectrum of sulphur have recently been published by me (*Zeit f Phys* **60**, 642 1930) As shown by Lindh and myself (*Ark f Mat, Astr och Fysik*, **18**, Nr 14 and 34, 1924 *Zeit f Phys*, **33**, 901 1925), the struc

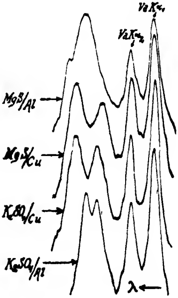

FIG 1

ture of the $K\beta$ lines of the elements sulphur and phosphorus does not depend only on the chemical state of the element under investigation, but also on the material used for the anticathode For some time I have been studying more closely this influence Some preliminary results obtained with sulphur, using aluminium for the anticathode, will be described here Of the various chemical compounds photographs are taken under the same experimental conditions as those in the work above mentioned (*Zeit f Phys*, **60**, **642**, 1930), where copper was solely used for the anticathode

On an aluminium anticathode magnesium sulphide gives except a rather intense β line with the wave length 5017 9 X U also a fainter, somewhat diffuse one of 5023 6 X U The difference in structure between

the β lines of magnesium sulphide on copper and on aluminium anticathodes is obvious from the photometer curves in Fig 1. The two lines at the right part of the figure are $K\alpha_1\alpha_2$ of vanadium, which are taken as reference. The photographs of calcium suphide show a rather sharp line at 5018 1 X U, which towards greater wave lengths seems to have a faint component at about 5021 X U. With strontium sulphide and barium sulphide the β lines have almost the same structure as on copper anticathode. However, the line 5018 3 X U with strontium sulphide on copper anticathode seems on aluminium to be separated into two lines. Also a very faint line at 5011 X U is visible with these two compounds. The broad emission bands, which were obtained with zinc sulphide and cadmium sulphide on copper anticathode are on aluminium separated into two lines, one rather broad and intense at 5017 1 resp 5017 0 X U and one fainter at 5023 2 resp 5022 1 X U. Further, the photographs of zinc sulphide show a faint line of 5031 3 X U and those of cadmium sulphide one of 5033 0 X U. At a closer investigation of the photographs of zinc sulphide and cadmium sulphide on copper anticathode here also small traces of these fainter lines are visible. Of the sulphides examined only copper sulphide holds its characteristic β doublet structure unmodified on aluminium anticathode. The peculiar structure of silver sulphide on aluminium (*l c Ark f Mat, Astr och Fysik*, 18, Nr 34, 1924) has anew been established.

Of the sulphates examined, only copper sulphate has the same structure on aluminium and on copper anticathodes. Fig 1 shows the difference in structure between the β lines of potassium sulphate on the two anticathodes. The wave lengths are on aluminium 5018 4 and 5014 9 X U, on copper 5020 6 and 5014 7 X U. The lowest curve is characteristic of the sulphates of the alkaline metals and the metals of the alkaline earths on aluminium anticathodes. Some of the sulphates also show a very faint and diffuse line of 5044 X U.

The wave lengths of the $K\alpha_1\alpha_2$-lines of the various sulphides on aluminium anticathode agree closely with the results obtained on copper. This is also the case with the α lines of the examined sulphates.

The results will be discussed more particularly when the present study of a larger experimental material has been finished.

The Binding Energy of Some Organic Compounds

MECKE (NATURE, April 5, p 526) has recently revised several of his older estimates of the energy of dissociation of C H and C C bonds in organic compounds, obtaining values considerably higher than before. In these new calculations it is assumed that (*a*) the energy of removal of all of the hydrogen atoms in, say, methane, is the same, and (*b*) the carbon atom will be left in the ^5S state with an excess energy amounting to about 110 kcal. It is then possible to calculate binding energies by the same methods which had been used before when instead of (*b*) the assumption was made that a normal carbon atom would be formed; clearly, the new energies will be higher than the old by 110/4 or 27 5 kcal for C H bonds, and 110/2 or 55 kcal for C C bonds. The dissociation energy for C-H in saturated hydrocarbons is thus increased from 90 kcal to 117 kcal, and that of C C from 65 kcal to 120 kcal.

This value for C H may well be correct for methane, but it is probably too high for the higher hydrocarbons; in support of this opinion the experiments of Bonhoeffer and Harteck (*Z physik Chem*, 139A, 64, 1928), may be mentioned; it was found that methane was perfectly inert to atomic hydrogen, but that all higher hydrocarbons were dehydrogenated, suggesting that the binding energy of the C-H bond in methane is greater than the heat of dissociation of hydrogen, 101 kcal, while in the higher hydrocarbons it is less.

The value 120 kcal for C-C is even more difficult to reconcile with chemical data. It has become clear within the last few years that the initial step in the thermal decomposition of saturated hydrocarbons takes place as a normal unimolecular reaction; the best value which can be given for the energy of activation in such reactions is about 65 kcal. It is rather likely that the binding energy of the bond which breaks in a unimolecular reaction is about equal to the observed activation energy, but in any case it cannot be greater than this energy plus the average energy of the reacting molecules at the temperature used. For propane at 600° this later quantity will scarcely exceed 10 kcal, giving about 75 kcal as an upper limit for the energy of a bond in this molecule. It is not likely that there are any C H bonds with so low an energy as this, and it may therefore be assigned to a C-C bond.

The conclusion which these facts suggest is that the old, lower values for the C C bond, and for C-H in higher hydrocarbons, are preferable, and therefore that the complete dissociation of such hydrocarbons will yield carbon atoms in the normal ^3P state.

Negative Attenuation of Wireless Waves

IN 1926 Ratcliffe and Barnett (*Proc Camb Phil Soc*, vol 23, p 300) directed attention to an anomalous effect which they had observed when measuring the attenuation of wireless waves of 1600 m wave length from 5XX, the Daventry station of the B B C. They obtained an attenuation curve of the form shown in Fig 1, which shows how the product ($E \times d$) of the

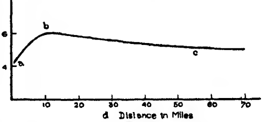

FIG 1

distance (d) and the electric intensity in the wave (E) varied as the distance (d) from the transmitter was increased. The falling portion (*bc*) of the curve represents, as is well known, attenuation of the waves due to losses produced by eddy currents flowing in the ground. The rising portion (*ab*) of the curve may be said to represent a 'negative attenuation' of the wave. At the time when the observations were made, no explanation of the negative attenuation could be given.

Since the publication of the original results, experiments have been performed to find out whether the negative attenuation effect is peculiar to the Daventry signals, or whether it occurs on all signals of this wave-

length Attenuation measurements made at Cambridge on a transmitter with a low aerial, working on a wave-length near 1600 m, showed no sign of the effect We therefore conclude that it is due to some special conditions at the Daventry site Two possibilities then present themselves either it may be due to the high aerial employed at Daventry (130 yd high), or it may be due to some special factors influencing the attenuation at the Daventry site It would be possible to decide between these two alternatives by investigating the attenuation at Daventry using a low transmitting aerial By kind permission of the B B C it is hoped to carry out this measurement in the near future In the meantime, it is of interest to investigate whether the effect could be produced by some peculiarities of the ground over which the wave passes This investigation can be carried out with the aid of some numerical calculations on Sommerfeld's attenuation theory (*Ann der Phys*, vol 28, p 665, 1909) which have recently been published by Rolf (*Proc Instit Radio Eng*, vol 18, p 391, 1930)

Rolf shows that, for certain values of the conductivity (σ) and the dielectric constant (ϵ) of the ground, we should expect attenuation curves of the form shown above, exhibiting the phenomenon of negative attenuation By comparison with these calculations we find that the observed curve can be explained if we assume $\sigma = 7 \times 10^{-15}$ e m u and $\epsilon = 80$ e s u The value for σ is not very different from that which has previously been found by other methods (tilt of the wave front, and attenuation on 400 m) The value of ϵ is, however, very different from that found previously (Ratcliffe and Shaw, NATURE, Oct 19, 1929, p 617), using waves of 30 m wave length We must, however, remember that there is every reason for supposing that both σ and ϵ will vary with frequency To investigate this variation, laboratory experiments have been carried out, in which these quantities were measured at different frequencies, for different specimens of soil It was found that ϵ increases as the frequency is reduced, and at 1600 m values of $\epsilon = 45$ were obtained for this quantity, and it was noticed that for these frequencies, the value of ϵ was increasing rapidly as the frequency was diminished It thus appears that here we have a possible explanation of the negative attenuation effect

Whether or not this is the correct explanation will only be clear when the measurements on a small aerial at Daventry are completed, and only then will we know whether the values $\sigma = 7 \times 10^{-15}$ and $\epsilon = 80$, deduced from the curve in this way, are correct

New Spectrum of the Hydrogen Molecule

In a recent note (*Physical Review*, May 1, 1930) I stated that I had observed a new system of absorption bands in hydrogen Since, because of its primitiveness, the hydrogen molecule is of great interest to physicists and chemists, I hasten to make these data available to other workers in this field Although at present the data are incomplete, I hope they are accurate enough to help investigators to establish another link between the ultra violet and the visible spectra of hydrogen and help clear up more of the ultra violet many-line spectrum

The new band system is especially interesting because it probably arises from the normal (A) state of the hydrogen molecule, and is by far the most intense of the hydrogen absorption spectra The observed bands are degraded to the red and form a v' progression representing transitions to vibration states connected with a new electronic level In harmony with former usage in the case of hydrogen absorption spectra, and pending a fuller investigation to establish its character, I shall call the new electronic level the D level The preliminary examination of this spectrum yields the following data The quantum designations, wave lengths, and intensities of the observed bands are (0 0) 838 62 (6), (1, 0) 825 85 (5), (2, 0) 814 32 (4), (3, 0) 803 86 (3), (4, 0) 794 23 (2), (5, 0) 785 75 (1), (6, 0) 778 18 (0), (7, 0) 771 35 (0) The formula that represents these is

$$\nu = 119244 + 1900v' - 59\ 524v'^2,$$

where ν is the observed frequency and v' the vibrational quantum number of the D level From these data it is seen that the molecular constants are $\omega_0 = 1900$ cm^{-1}, $\omega_0 x = 59\ 52$ cm^{-1}, and $D = 1\ 872$ volts, the energy of dissociation from the D state of the molecule

Using the value 4 465 volts as the heat of dissociation from the normal state in connexion with the data given above, one sees that the products of dissociation are a normal atom and one excited to the 3 quantum state The value thus deduced for the 3 quantum state of the atom is 12 22 volts, whereas the true value is 12 035 The discrepancy is not large, and is in the right direction when one considers that a linear formula was used to fit the data of the ω_v curve A further comparison of these data with the great amount of hydrogen data made so conveniently available by Prof Richardson in his report to the Faraday Society shows that the D level is quite new and that its denominator is 4 538

Some recent photographs showing some of the rotation lines of these bands are being examined in order to extend the analysis and to attain greater accuracy

Association of Stimuli in the Development and Function of the Nervous System

An interesting connexion is to be found between two recent conceptions of the nervous system, in its development and function Pavlov's work indicates that the function of the cerebral cortex is the setting up of conditioned reflexes These, together with unconditioned reflexes, underlie the behaviour of an animal The conditioned reflexes are elaborated by association with unconditioned reflexes, " their function and extinction are determined by (one or several) coincidences in time of stimulation of the lower lying reflex centres, with the stimulation of the cerebral hemispheres through the corresponding centripetal nerves " (" Lectures on Conditioned Reflexes ", p 74) The *association* of stimuli (those causing unconditioned with those causing conditioned reflexes) is a fundamental factor in the nervous activity of an animal For example, the ringing of a bell will cause a dog to salivate (conditioned reflex) provided the sound of the bell has previously accompanied contact of meat with the dog's mouth, causing salivation (unconditioned reflex) It is the simultaneous or approximately simultaneous occurrence of different stimuli which is responsible for the creation of the conditioned reflexes constituting animal behaviour Thus the *function* of the cerebral cortex is dependent upon the concurrence of physical stimuli

Compare this with the theory of neurobiotaxis, formulated by C U A Kappers, which accounts for the *development* of the nervous system, and the material connexions in it In this case, associated

physical stimuli from various regions of a growing embryo are thought to determine the formation of the parts of its nervous system Kappers says "In the case of material alterations in the nervous system, only simultaneously associated influences cause the selection simultaneous (or immediately successive) stimulations bring about not only mental associations but also material connexions in the nervous system" ("Three Lectures on Neurobiotaxis and other Subjects", p 19)

It appears from the experimental work of Pavlov, Kappers, and other workers, that both the development of the nervous system and the function of its highest part, the cerebral cortex, are dependent fundamentally upon the occurrence of physical stimuli associated with each other in space and time The importance of this conception for science is obvious Since the mind is dependent upon the activity of the cerebral cortex, these recent theories of its development and function may not be below the consideration of philosophers

The Neon Lamp as a Glow Relay

THE ordinary 'Osglim' neon lamp as made by the General Electric Co, Ltd, forms a convenient and sensitive glow relay if furnished with a third electrode which may take the form of a strip of metal foil 1½ in wide, pasted on the outside of the lamp to surround the internal electrodes The type of 'Osglim' lamp most suitable is that known as the beehive, in which the electrodes take the form of a disc and spiral

This form of glow relay is sometimes conveniently used in conjunction with a photo electric cell, to indicate when a required light intensity is falling upon the cell

The disc electrode of the lamp is connected to the negative end of a battery, and the voltage adjusted on the spiral until the glow discharge is just avoided, usually about 132 volts is sufficient

The external electrode of the neon lamp is connected to the cathode of the photo electric cell, and the anode of the cell to a suitable positive tapping on the same battery Illumination of the cell will then promote discharge within the neon lamp passing sufficient current to operate a magnetic relay

The glow relay with the external third electrode enables two circuits to be kept entirely separate from one another Not every 'Osglim' neon lamp is suitable, due to variations in the insulation resistance and probably also to less suitable gas pressure

These neon lamps also exhibit a photo electric property, if the voltage on the third electrode is just raised sufficiently to produce the discharge, illumination of the electrodes by, say, a gas-filled lamp will prevent but not discontinue the discharge

'Digging' in Rowing

IN most cases where a solid moves through a fluid, the total force of the fluid on the solid is nearly opposite to the direction of relative motion There is an exception in the case of a flat body such as an aeroplane wing, with its plane at a small angle to the direction of relative motion In that case the force is nearly at right angles to the direction of relative motion, and provides the means of keeping the aeroplane up If, however, the plane is too steeply inclined to the direction of motion, the force is again, as in ordinary cases, nearly against the motion, and we have the condition of 'stalling'

In rowing, the object is the opposite one, to keep the force as far as possible against the relative motion, but it seems to be worth while to point out that an oar can be turned into an aeroplane Imagine the blade inserted thus, and moved from right to left,

the blade being slightly inclined to the surface of the water Then the same theory applies as for an aeroplane wing, except that the leading edge is now the lower one Hence the force due to the water is *downwards* But the force due to the oarsman's pull is in the direction of motion, and no steady motion in a horizontal direction is possible If, on the other hand, the blade descended vertically, the force due to the water would become a resistance acting upwards It will be seen on a little consideration that the only possible motion is an accelerated one nearly in the plane of the blade, and resisted almost only by skin friction Thus the oar will rapidly shoot down to a considerable depth, while doing little to propel the boat

The phenomenon is, I understand not unfamiliar to oarsmen, especially when the blade is left near the 'feathered' position when reinserted in the water

The Accuracy of a Moth

THE square case made by the female of *Amicta quadrangularis* for pupation offers a good example of the ability for accuracy The case is about 1 1 inch long, and 0 2 to 0 3 square, formed of bits of grass stem broken off, and built in courses around the larva The diagram (Fig 1) shows the mean size of the

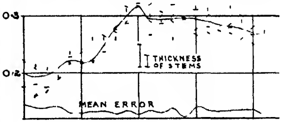

FIG 1

pieces beginning at 0 2 inch, widening to 0 32, and tapering to 0 27 The lengths of stem used on different sides are distinguished by four directions of the cross strokes It will be seen that the mean error, separately drawn below, begins at 0 02 and diminishes to 0 01, while the thickness of the stems varies from 0 04 to 0 02 inch The larva, therefore, makes an average error of only one half the thickness of the stem, and estimates the required length for the position usually to 0 01 inch, including the error of cutting, this precision is kept up for nearly a hundred repetitions A few layers near the beginning are omitted, as they overlap so that the ends are not clear The habitat is in the desert of South Palestine about ten miles south of Gaza

The 1851 Exhibition Commissioners and their Work

THE Commissioners for the Exhibition of 1851 have published records of their scholarship schemes and the Press has directed public attention to prominent features in the results of the work of the Commissioners in this section of their activities. The *Times*, in referring to the remarkable results of the first and greatest of these schemes, has paid tribute to the foresight of the chief promoter of the Exhibition—Prince Albert. The tribute is indeed well merited. It was due to the Prince's vision that the Royal Commission was established for the Exhibition and was continued thereafter on a broader basis and with powers that enabled it to function to public advantage—with results perennial and far beyond the scale of its own material resources.

SCIENCE RESEARCH SCHOLARSHIPS

The essential factor in the influence of the Commission is its powers of initiation and demonstration. This feature is well illustrated by the scholarships' scheme, which did not take shape until forty years after the establishment of the Commission. In the course of these years the Commissioners had done a great deal to inspire the development of 'system' in national services for the promotion of science, art, and the industries; they had secured an estate in South Kensington as a 'locality' in which the State and other authorities could erect central institutions pertinent to such services.

It is clear that in the 'eighties the Commissioners came to the conclusion that *men* were lacking for the further development of their ideals, and the occasion produced the man who could find and 'make' such men—Lord Playfair—as Dr. Lyon Playfair, a commissioner from 1869. He acted as honorary secretary from 1883 to 1889, and in that period he carried through a process of financial change which replaced a deficit of the Commissioner's income in 1883 by a surplus of £5000 in 1889. He originated the Science Research Scholarship scheme, and, as chairman of the Scholarships' Committee for its first five years, he may well be said to have established the scheme.

The governing statement of that scheme is that the scholarships are "awarded to students who have passed through a university curriculum and have given distinct evidence of capacity for original research—to enable them to continue the prosecution of science, with a view to its advance, or its application to the industries of the country." From its inception the scheme took cognisance of students of universities overseas as well as of those at home. Right well has the scheme justified itself! The published "Record of the Science Research Scholars" gives ample evidence of the great and varied field the scholars have helped to enrich.

Conceived and maintained with full expectation of concurrent advance in the standard of preparation provided in the universities, the scheme met the needs for thirty years. In 1922 it was revised in view of the large development that had then taken effect in universities. From that year the awards have been under two categories: (*a*) Overseas Scholarships for selected students of universities in Canada, South Africa, Ireland, Australia, and New Zealand; (*b*) Senior Studentships for selected students of exceptional promise and proved capacity for original work. The Commissioners make their awards by selection in view of the recommendations of the institutions submitting names of candidates.

It will be noted that the change made in 1922 reflected a marked and welcome advance in the standards attainable within the limits of the facilities prevailing in the universities of Great Britain. By 1922 the universities had indeed been enabled to extend very materially the facilities they provided for advanced study and research—alike as to accommodation, facilities, and expert supervision and guidance. This provision has since been steadily increasing; in the past five years gifts from private benefactors and the financial help of the State through the University Grants Committee have made possible in the universities many advances in facilities and on staff that were, twenty years ago, but dreams.

The "Record of the Science Research Scholars" of the Royal Commission is remarkable—giving, as it does, for each 'scholar' particulars of his subsequent career. The pages of the list of scholars sparkle with names that call up most fruitful contributions to the progress of science! And, where personality counts for so much, it is refreshing to see in how many and how varied paths of life and lines of work these ex-scholars have rendered yeoman service and have been much sought after. Here is but a bare indication; yet even this is illuminating:—From 1891 to 1929 the number of those who passed out of their scholarship period is 562. Of these 7 died before obtaining scientific posts and 5 discontinued scientific work on the expiration of their scholarships. Of the 550, 240 engaged in teaching in universities (109 of them in the British Isles, 99 in the Dominions and India, 26 in the United States, and 6 elsewhere), 29 engaged in teaching in technical colleges and schools, 54 in research in universities, 91 entered public services, and 136 engaged in industries.

In reading these figures it must be remembered that a large proportion of those who become engaged in teaching continue their research work, and that not a few of these render expert assistance to industry; and, again, 'public services' to-day call for much specialised research which, in one way or another, reacts on industry. Indeed, careful reading of the detailed statements of the "Subsequent careers of Scholars" shows that their services to industry are both surprising and ubiquitous. The Record must be read: it is a document of great human interest.

Incidentally, the tabulated statements afford ample evidence of the extent to which the work of the 'scholars' has earned for them the appreciation of their fellow-workers in science and in the

industries To take one example 32 who had been 'scholars' are noted in that Record as having been elected fellows of the Royal Society, and this year's election has added 3 more

The Cost and How it has been Met

Now what does all this cost? The Senior Studentship and the Overseas Scholarship Schemes —together replacing the previous Science Research Scholarships Scheme—cost £11,000 a year This annual expenditure is greater than the interest on the whole capital of the Commissioners in 1852, and the Commissioners support other educational ladders

The surplus on the accounts of the 1851 Exhibition was £186,000, and the Commissioners have contributed liberally in sites and subsidies for the promotion of education in science and art—in every case deliberately and, with rare exceptions, with most fruitful results The particular case of the Science Research Scholarships illustrates the discriminating care the Commissioners exercised in initiating the service forty years ago and their continuing attention to the purpose and conduct of the scheme This particular scheme was—at its inception—a new departure and called for skilled and careful preliminary inquiry In these respects it was typical of most of the schemes they furthered or initiated When conceived, however, it had to face a particular difficulty In a later section of these notes it is stated that in 1877 the Commissioners aimed at establishing scholarships, but they could not then do so They had first to pay off debt incurred in developing their estate—the reserved part for public benefit, the outer ring for sale or long leases The Scholarship Scheme had to wait until they could float it—by the materialising of their area plan

The fact is that from 1850 the Commissioners have been 'Venturers'—not 'Merchant Venturers', but venturers in ideas relevant to progress in science, art, and industry The Science Scholarship Scheme was one of their 'ventures'—one of many It has been dealt with *here* as a type, and *now*, because its results have just been subjected to a long term audit Its place in the labours of the Commissioners, and in the unwritten and, indeed, impossible estimate of the services they have rendered to intellectual and material progress, can be visualised only by a wide survey of their work

The purpose of the following notes is to indicate briefly the record of their other ventures and to point to prominent achievements either by way of marking out promising fields or in exploring and testing little-known paths that might prove valuable lines to progress

The Royal Commission of the Exhibition of 1851

The present generation does not know the debt of gratitude it owes to the men who, in 1850, were incorporated as "The Royal Commission for the Exhibition of 1851", nor, indeed, did the previous generation. Those of *three* generations ago credited the Commissioners with great energy and sound judgment in promoting the success of the Exhibition After "1851" had set men a thinking, many noted with pleasure the continuous effort of the Commission to secure the full fruits of the ideas the Exhibition had sown widespread Quietly but steadily fruits were garnered and fresh areas enriched

How came it that the Exhibition could prove so effective a stimulant and how did its influence become permanent? The Commissioners appointed in 1850 were picked men—selected as representing the best and most active powers in many types of work—and they had in their chairman, Prince Albert, one familiar with the aims and methods in view—immediately and ultimately—one quick to understand conditions and energetic in securing action on decisions reached by the team he led The Prince Consort had been president of the Society of Arts for some years, in the course of which that Society had made a good beginning in the exhibition of British manufactures The Society proposed for 1851 an Exhibition of an international character and petitioned Royal sanction for the undertaking The Royal Commission and the Charter of Incorporation were issued early in 1850

The Exhibition

The Commissioners got to work at once They secured strong committees for the activities required at headquarters, and local committees were appointed in 297 towns and districts "Several gentlemen were selected to visit the more important towns" The newspapers gave valuable aid Despite many difficulties the Exhibition building—soon commonly known as the Crystal Palace—was erected on a site to the east of that on which the Albert Memorial now stands

The Exhibition was opened on May 1, 1851, by Her Majesty Queen Victoria

The Commissioners had worked hard they had gathered an able staff and they had roused enthusiasm in all centres of population, manufactures, and industry in Great Britain and Ireland, they had established relations with foreign countries and had elicited hearty and instructed co-operation in very many centres

The building was ready in good time The Exhibition contained contributions from nearly 14,000 exhibitors, of these, 53 per cent were from the United Kingdom and Dependencies and occupied 65 per cent of the total exhibition space, while 47 per cent were foreign and occupied 35 per cent of the space The exhibition was indeed international

These figures are taken from the "First Report of the Commissioners", published in 1852—a report which is a mine of interesting information it embodies many instructive details of arrangement and propaganda, of precaution and of record One inconspicuous item of record may be mentioned as affording an early example of the graphical illustration of related statistics This is a sheet of three diagrams printed in colours "Fig 1 Diagram showing fluctuations in the number of visitors, as affected by different days of the week,

different scale of payment, rain and heat of the building" "Fig 2 Diagram showing the relative fluctuation [in the numbers of visitors] on different days of the week [in successive months]" "Fig 3 Diagram showing the number of visitors actually in the building at every hour on three separate days" There is much of human interest in the appendices to the Report

In the body of that first Report, April 1852, the Commissioners stated that the surplus of the Exhibition accounts after the discharge of every liability would be not less than £150,000 The one major point of uncertainty then was the disposal of the Exhibition building, which had to be removed from Hyde Park In the end the "Crystal Palace" was bought by the "Crystal Palace Company", which had been formed for this purpose That Company took down the building and re-erected it at Sydenham

THE SURPLUS

When the Commissioners closed the Exhibition account in 1855, the amount at the credit of the account was £186,436 18s 6d This sum was then transferred to their Estate account, which had been opened by that time In the early months of the Exhibition it had become clear that there *would* be a surplus, and that this might be considerable It is on record that the Prince Consort was giving close attention to this matter in August 1851 Soon after the close of the Exhibition the Commissioners petitioned Her Majesty for a supplemental charter enabling them to prepare and submit a scheme for the application of the surplus, and, if their scheme were approved, to put it in operation Such a supplemental charter was granted on Dec 2, 1851

The Commissioners early satisfied themselves that no substantial national advantage would accrue if they were to distribute the surplus—as they had been pressed to do—among the areas that had contributed to the success that had attracted receipts They had made a careful survey (Second Report, 1852) of the existing position as to central and local institutions working in the interests of science, the arts, manufactures, the raw materials and the processes required in industries They had come to the conclusion that the most urgent needs were (i) improved conditions for the work of central institutions and (ii) the wide spreading of effectual methods of education and investigation bearing on these interests By their effective propaganda work in the preparation of the collections for the Exhibition, they had prepared the people and the Press for a forward movement in these matters The Exhibition itself had done much to stimulate thought and action which, well guided, might go far in its results

AFTER THE EXHIBITION—THE ESTATE

The assets of the Commissioners as disclosed in their Report of November 1852 were, in fact, their surplus *and* an idea The surplus was highly gratifying the idea was of even greater value 'System and a Locality' was their watchword They urged more systematic facilities for study and advance in science, the arts, and industries They proposed to find room for central developments on a systematic basis, and to leave to individuals, corporations, and authorities the promotion of the different interests that concerned them They had themselves taken preliminary steps to secure a 'locality' In 1852 they arranged to purchase, at a cost of £60,000, the Gore House estate of 21½ acres Profiting, however, by the unfortunate experiences of other authorities in acquiring property in London, and knowing that the Government had been repeatedly urged by Parliament to provide an extension of national institutions, they took steps to secure national control of a larger area than was required for their own purposes They passed a resolution authorising the outlay of a sum not exceeding £150,000 of the surplus in the purchase of land, including the Gore House estate, on condition that the Government would recommend Parliament to contribute a like sum towards the purchase of land on terms to be arranged The Government gave this assurance The de Villars estate and portions of the Harrington estate were purchased under this agreement, which, in practice, amounted to a temporary partnership These purchases enabled the Commissioners to lay out this group of properties for buildings of determined types, and to construct roads on a scale conformable with their general scheme

LOCALITY

Their scheme contemplated that there should be preserved for public purposes (*a*) almost the whole of the area extending between the Queen's Gate of to day on the west and Exhibition Road on the east, and from Cromwell Road on the south to the site on which the Albert Hall now stands, (*b*) the south eastern block of land now identified with the Victoria and Albert Museum

The latter block of land was taken over by the Government for £60,000 in 1861 The iron building that formed the nucleus of the South Kensington Museum—now the Victoria and Albert Museum—was erected on it in 1857, and was formally visited by H M Queen Victoria and Prince Albert, previous to its opening to the general public Further, more permanent, sections surrounding the garden court were erected in the course of years, and the main building which occupies the south and west fronts, and indeed the major part of the site, was opened by H M King Edward VII in 1909 The other buildings on this section of the area are on its north-western corner these are the original building of the Royal College of Science on the Exhibition Road front, and the Royal College of Art behind

In 1864 the Government bought from the Commissioners, for £120,000, the ground in the centre of which the Natural History Museum now stands On the north-eastern corner of this area the new building for the Geological Survey and Museum is now in course of erection

In 1888 the Government took over from the Commissioners for £100,000 the ground and buildings

between the foregoing block of land and Imperial Institute Road

Each of these three land transactions was governed by the restriction of the use of the site to "purposes connected with Science and Art", and in view of this condition the transferences were made at less than half the market value of the ground at the times of sale

These transfers concluded the major sales of land in the history of the Commission The net result appears to be that (1) the Government obtained on most favourable terms two great sites of first-rank value, (2) the Commissioners retained under their own control an adequate central area for the development of institutions in furtherance of their aims, and (3) the Commissioners retained a surrounding area available for sale or lease for beneficial occupation by others on terms which would regulate the amenity of the locality and at the same time yield, from sales and ground rents, a satisfactory revenue for disposal by the Commissioners in furthering the objects for which the Comsion was established

SYSTEM

In their Second Report (1852) the Commissioners directed attention to the need for further and more systematic efforts for the promotion of science and art in Great Britain—instruction for its industrial population—facilities for the exchange of results of study and investigation between investigators as well as between these and the public In their Third Report (1856), they refer to the establishment of "the Department of Science and Art" in 1853, and they record and illustrate the establishment or strengthening of various central and provincial institutions engaged in promoting science, art, and the industries, or in bringing inventions, designs, etc, before the public by museum representation Truly the seed had been wide scattered and was burgeoning well Yet not even to day do we see the full crop The prospects, however, are promising

The Department of Science and Art proved to be an effective pioneer Active local authorities soon found in the Department a perennial fountain of assistance—trickling at first, but always helpful To day the activities it fostered in all parts of the country are fed systematically through the Board of Education and Local Authorities They gain strength steadily

In 1852 the Commissioners had refused to distribute cups from the spring of enlightenment Obviously they preferred to work for the development of a real and liberal national supply system Being wise, they did not advertise their expectation The occasion was not opportune nor was the prospect promising Their work did much to promote the aim, but they could not have imagined that the full development of 'System' would be a matter, not of years, but of generations !

THE PRINCE CONSORT

In December 1861 the Prince Consort died The Commissioners, in their next Report (1867), wrote "The Address presented by us to Her Majesty on that sad occasion embodies the sense entertained by us of the irreparable loss we are called upon to sustain by the great Prince's removal from our head—a loss the extent of which each day's experience only tends to confirm"

We of the third and fourth generations sympathise most fully We also rejoice in many and bountiful crops which his vision and the wise administration of his successors have secured

(*To be continued*)

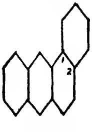
Tar Cancer

THE fact that workers in the shale industry show a relatively high incidence of cancer led to the discovery that certain tar products which had been exposed to high temperatures could produce cancer when painted on the skin of mice It was then found at the Cancer Hospital Research Institute that heating a variety of materials, such as acetylene, cholesterol, human skin, muscle, or hair, and yeast, to temperatures of 700° 900° resulted in the production of carcinogenic agents Attempts were next made to produce similar substances at lower temperatures, and Schroeter, some years ago, found that when aluminium chloride acted upon tetralin (commercial tetrahydronaphthalene) at 30°-40°, a mixture of high boiling compounds was formed

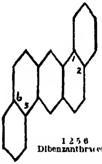
E L Kennaway and I Hieger (*Brit Med Jour*, June 7, 1930, p 1044) have recently reported that this material is carcinogenic as well as that prepared at 60°-70°, they noticed that the concentration of the aluminium chloride had to be above a certain minimum and that the treatment had to last a certain minimum time for the production of active material Later observations suggested that the carcinogenic agent might not be produced in effective amount at body temperature, but that its concentration was increased by the heating necessary to distil off the unchanged tetralin This line of research was, however, temporarily dropped when the authors noticed that this carcinogenic material shows a blue violet fluorescence, especially intense in a beam of ultra violet light The fluorescent light gives a spectrum with three bands at approximately 4000, 4180, and 4400 A

Examination of a large number of pure hydrocarbons and other substances was then undertaken, but without the discovery of one showing these bands 1 2 benzanthracene, however, gives three, resembling them in character and position relative to one another, but lying slightly nearer to the invisible region Addition of aliphatic or aromatic side chains to the benzanthracene molecule shifted the spectrum towards that of Schroeter's mixture, but none of these compounds has yet been found to be carcinogenic Condensation of another benzene ring with the benzanthracene nucleus

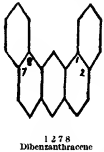
produced some compounds which both showed the three bands (but again shifted towards the invisible region) and were at the same time carcinogenic. The 1 2,7 8 compound was the most potent, but tumours were also produced by compounds of the 1 2,5 6 series.



1 2 Benzanthracene



1 2 5 6 Dibenzanthracene



1 2 7 8 Dibenzanthracene

Twort and Fulton found that chrysene is carcinogenic; its fluorescence spectrum is similar to that of benzanthracene but lies considerably nearer the region of short wave length.

The spectrum of Schroeter's mixture is given by a number of carcinogenic tars, including those obtained by heating certain animal or vegetable tissues. If acetylene tar is saturated with chlorine the bands are shifted towards the benzanthracene position and the carcinogenic potency at the same time reduced. Certain carcinogenic agents fail to give the bands, whilst a few substances showing them are not carcinogenic. It thus appears that the spectrum is not specific for carcinogenic agents, but the presence of the spectrum without activity may merely indicate that a carcinogenic agent is present but in too low a concentration to affect the skin of a mouse; the fluorescence test is a much more delicate one than the production of cancer in mice. The frequent occurrence of this spectrum may, however, prove useful in the preliminary examination of various substances suspected of carcinogenic effect, and may finally lead to the detection of a pure compound or compounds having this action. When reached, this result may throw light on the origin of cancers developing spontaneously.

Obituary

Dr Fridtjof Nansen

DURING most of his lifetime the whole world has acclaimed Fridtjof Nansen as a man of the first magnitude, and his fame has grown as his years increased. His outstanding figure shines in history by its blending of almost all the elements of human greatness, and probably this is why the press writers of to-day, when setting forth his claims to immortality, have so often been swept away in a flood of panegyric. I knew Nansen for forty-one years, from the time of his first crossing of Greenland, throughout the struggle to launch his *Fram* expedition, and the laborious years spent over the scientific reports on the work it accomplished. I was with him year after year at the meetings of the International Council for the Exploration of the Sea, and at other scientific gatherings in many lands. He was frequent in his correspondence on questions regarding our common interests and the glow of his unfaltering friendship warmed my life. Knowing the difficulties he had to overcome as well as the triumphs he achieved, I trust that it is not presumptuous for me, now that few remain who knew him better, to survey his career from the point of view of a contemporary.

Thirty-four years ago I reviewed in these columns (NATURE, Dec. 31, 1896, vol. 55, p. 201) an English translation of the life of Nansen, which was written when most people believed that he had perished in the Arctic. There is little in that article that I wish to change, and it may still be read as supplementary to this.

Nansen had a great heredity in which the elements of his own personality can be clearly traced. Without going back to the old Viking strain which came out in his magnificent stature and rugged features, we find full proof in the recorded family tree. His great-great-grandfather, born at the end of the sixteenth century, was a Dane, Hans Nansen, who as a lad spent a winter frozen in the ice of the White Sea, as a young man commanded a ship in the Iceland trade and wrote a book on the wonders of the sea, later becoming *Burgomaster* of Copenhagen, a prominent politician and a fervent patriot. His grandfather, Hans Leierdahl Nansen, nearly a hundred years later, was a Norwegian by settlement, a judge and government official, a keen politician, a man of many words rather than of action, but a patriot of the perfervid type, determined, if Norway must enter into close alliance with Sweden, that there should be no phrase in the treaty of union which could imply any inferiority in the partnership. His father, magniloquently named Baldur Fridtjof Nansen, and an aristocrat on his mother's side, was a quiet, studious man, occupying a responsible position in the legal profession, indifferent to outdoor sport, very strict in his parental oversight, governed in all things by inexorable principles. His mother, on the other hand, was a practical, energetic, strong-minded person who, as a girl, had horrified the prim society of the period by taking up the unmaidenly sport of ski-running, in which she excelled.

Nansen was born on Oct. 10, 1861, in a small country house at Store Froen in Aker, near Oslo; they gave him the name of the hero of an old saga, and never was there an apter christening:

As the acorn wins to a sapling, as the sapling waxeth an oak,
A goodly guard of the forest, and fronting the storm-wind's stroke,
So grew in his beauty Frithiof; he waxed a man among men;
In his heart was the love of all things, and his might was the might of ten.

Like his namesake of the northern mists, young Fridtjof grew up in the open, bathed in the ice-cold waters, risked his life a hundred times on fjord and fjeld, and beat all his comrades in every manly sport When a student his name was noised abroad as the champion ski-runner of Norway, and his holiday excursions over the high fjelds in winter were marvels of endurance He was probably no better at book learning than most of his contemporaries at the University of Christiania His true education came from his contact with Nature in a land where the contrasts of scenery, of climate, and of season are at a maximum, serving by turns to sting life into action and to awe thought into sombre introspection A strong poetic vein came to him from his ancestors in the midst of his most strenuous exertions he would give expression to emotions that an ordinary athletic Englishman might be tempted to scorn as sentimentality, yet they were part of the man

At the age of nineteen Nansen decided to take up biology as his life work Text-books did not attract him, but research was a mode of learning that made an appeal To take a real grasp of any truth he had to discover it, or at least to recognise it, for himself Priority was a question which did not trouble him at any time, in conducting an investigation he was intent on solving a problem which interested him mainly as a difficulty which he had undertaken to overcome

Nansen's biological researches won for him the curatorship of the Bergen Museum and his Ph D degree, they were characterised as promising by the specialists, but they were probably little in advance of the average of post graduate work Biology was not the master passion of Nansen's life, but it set him on his way when, in 1882, on board the sealer *Viking*, in the investigation of the polar fauna he first saw Arctic ice At the age of twenty six he seemed to be heading for a comfortable biological chair in a university, but the spirit of his fathers had leaped from the northern waves and pointed to another field of fame

It is difficult for the present generation to realise the opposition to which Nansen's project of crossing the Greenland inland ice gave rise Whymper, Nordenskiöld, and Peary had all tried to advance over the ice cap from the west coast and all had failed This young man resolved to succeed, first halving the distance to be traversed by starting from the east coast and providing no line of retreat He wished to go forward, and forward he had to go, for there was no possibility of going back He was to take a small party, and he devised light gear and special cooking apparatus The authorities said no one could carry out such a plan, Nansen knew he could, and he did He had been sure of success from the first and upheld his faith in himself with a firmness that would have struck a stranger as presumptuous obstinacy but for his modest bearing and the disarming sweetness of his smile

Nansen's natural self-reliance and stubbornness were increased by his success and by the year's lecturing in all parts of Europe which followed His mind conceived the far more ambitious project of reaching the North Pole Impressed by the extent and strength of the East Greenland Current and the vast quantity of ice and drift wood which it carried southward between Greenland and Iceland, he studied the problem of its origin and arrived at the conclusion that it must arise near the Siberian coast and probably flow across the pole He proposed to reach the pole by "taking a ticket with the ice", so he put it, from some point north of Siberia, and letting it drift him across, be the time required what it might He was confident in his own deductions and in the strength of his ship He planned her not to resist the ice but to compel ice-pressure to lift her on to the surface of colliding floes Once again he relied on the Forward policy, providing no line of retreat, staking his life and reputation on his faith in an idea In the words of his mythical namesake, he might have said to those who tried to turn him from his purpose

Now once for all I have chosen, the cost of my choice
I know,
And there lives not the man shall stay me the way that
I choose to go

Like his mythical namesake, too, he had an invincible ship, and a crew of true men, all equals, messing together and working together, and all devoted to their leader The ship he named *Fram*, which means 'forward', and forward he went, defying all the rules of earlier polar exploration Again, in the teeth of all expert advice and every traditional dictate of prudence, Nansen achieved success, though he did not reach the pole

Nansen's fame was established, but there was no change in the man He could not be any surer of himself or any more determined in the assertion of his own opinion than before, but he stood the storm of applause, unperturbed by the medals and the orders, the banquets and the flatteries, the publicity and the fortune which resulted I have known almost all the great explorers of my time, and Nansen was the only one on whom an overwhelming success left no jetsam of deterioration His manner remained as modest, his smile as winning as before Not that he attained to any superhuman perfection He still liked to draw the public eye, though he no longer displayed his fine figure in the tight fitting athletic costume which attracted so much attention in the streets of the capitals after the Greenland expedition He had not foreseen the depth of the Arctic Sea, and his oceanographical apparatus was inadequate In his great march on the ice he had let his watch run down and lost his longitude, but from a boy he had felt himself under the influence of a lucky star and he had won through by sheer force of body and mind

Physical oceanography took the first place thenceforth in Nansen's researches, and for several years he worked on the "Reports" of the *Fram* expedition, striving to make up for inadequate equipment by getting the very utmost out of the cleverly devised emergency methods used on the great drift The scientific results were certainly of far-reaching value, but the chief glory of the *Fram* expedition was that it gave the death-blow to the

Recent Discoveries of Fossil Man *

By Sir ARTHUR KEITH, F R S

GARDARENE MAN

A REMARKABLE discovery was recently announced by Dr F C C Hansen, professor of anatomy in the University of Copenhagen Prof Hansen is the leading authority on all that relates to the anthropology of Greenland, his monograph on the craniology of the Eskimo being the standard treatise on this subject Recently he received from Greenland a series of human bones discovered during the excavation of a twelfth century grave yard which had been attached to the cathedral church of Gardar (Igaliko), south west Greenland In one grave the remains of a bishop were found with crosier by his side and gold ring on his finger, the other graves contained the bones of Norsemen (Vikings) who settled on the west coast of Green land, just north of the southern end, early in the eleventh century Amongst these bones Prof Hansen discovered a lower human jaw and a large part of a human skull manifesting characters more primitive and more massive than even those of the Rhodesian fossil skull These peculiar bones were not fossilised, they were in the same condition as those of the twelfth century Norsemen

There is a possibility, seeing how prehistoric the Eskimo are in feature and ways of living, that some belated representative of fossil man—okapi like—might have survived in Greenland until Norse times and his remains might have thus come to be buried in an early Christian cemetery Having seen only imperfect accounts of what had been found, I wrote to Prof Hansen, who, although he has not published the results of his investigation, has with great liberality sent me drawings and photographs and a full description of the remarkable specimens which have come to Copenhagen That the bones represent an extraordinary and undescribed type of man there cannot be a doubt The lower jaw is more massive than has ever been found in a human face—yet it is regularly formed and of enormous strength That part of the base of the skull to which the neck is attached has expanded into great plate-like buttresses of bone The hinder (occipital) part of the skull is sharply bent as in the Java skull, the newly discovered Peking skull, and in the Rhodesian skull The temporal muscles of mastication have expanded upwards on to the top of the head until they almost meet—as in the female gorilla Although the fore head has been partly lost, it is clear that it was low and receding, and that the skull must have been of enormous length (235 mm)—nearly an inch longer than the longest fossil human skull known to us But, like early fossil skulls, it was very low in the roof—the vault rising not more than 108 mm above the ear passages The face was two inches longer than the face of the average Norseman The walls of the skull were not unduly thickened, but certain appearances in the finer structure of the bone suggest that growth was not quite normal

To this old but undescribed and hitherto un recognised type of humanity, Prof Hansen has given the name *Homo gardarensis* The problem anatomists have to solve is How did *Homo gardarensis* come to be buried in an early Christian Norse graveyard in Greenland? Prof Hansen will have nothing to do with the 'okapi' theory—he refuses to suppose that a prehistoric type of humanity could have survived in Greenland, there is no trace of Eskimo in Gardarene man The explanation he offers is this Certain of the Norse graves contained bones of big headed, very muscular men He thinks that in an isolated Norse colony, where families of exceptional strength of body had been segregated, there had been a degree of in-breeding which called forth in some child the latent inheritance of antiquity, that *Homo gardarensis* may therefore be looked upon as an atavism—the reproduction of a type of man long since extinct

In the Museum of the Royal College of Surgeons there is a series of skulls which throws light on the nature of *Homo gardarensis* Twenty years ago I became interested in that peculiar disorder of growth known as acromegaly—a disorder due to a derangement in the organs of internal secretion, the pituitary gland being the one chiefly at fault The skulls of men who suffer from acromegaly, assume—in a bizarre form—all the characteristics of the

* Abridged from six lectures given in the Royal College of Surgeons of England on May 5, 7, 9, 12, 14, 16, 1930

skulls of ancient fossil man—particularly Neanderthal and Rhodesian characters Giants, however, particularly in the first stage of this disorder, assume such cranial characters in a much more regular way—all parts of the jaws, face, and skull proceeding to a harmonious excess of growth Certainly the specimens described by Prof Hansen exceed in size and regularity the giant specimens in the Royal College of Surgeons, but they are manifestations of excessive growth of the same kind *Home gardarensis* must have been the subject of a disorder of growth—the kind of disorder which causes giantism in man, but whereas in most giants growth soon becomes irregular, in *Homo gardarensis* it remained regular

When we have classified this strange descendant of a Viking with giants we have not explained all The growth mechanism which is in each of us is a heritage from fossil man It is therefore quite possible, as Prof Hansen maintains, that *Homo gardarensis*, although not found in a fossil state, may reproduce a stage of man's evolution which may yet be actually discovered in a fossil state The Gardarene skull in some points resembles that of giant O'Brien in the Museum of the Royal College of Surgeons, in others the skull of the Bristol giant—Patrick Cotter, described by Prof E Fawcett in the *Journal of the Royal Anthropological Institute*, Vol N S 12, p 196, 1909)

Colonisation of Europe by Neanthropic Man

The pioneers who took possession of Europe on behalf of the white (Caucasian) race of mankind began to arrive at a certain phase of the last period of glaciation There is still a wide difference of opinion amongst experts as to the number of times northern and central Europe became entombed beneath an ice sheet during the Pleistocene period, but nearly all are agreed that the last ice age was divisible into three phases There was an opening phase marked by great falls of snow and a southward spread of the ice-sheet, there was a middle phase, very cold but comparatively dry when central Europe took on the aspect of the steppes of Russia, then came the third or final phase, one of great snowfall and severe cold This triple division of the last ice period, so important to the student of fossil man, seems to find an explanation in a theory recently formulated by Dr G C Simpson,[1] who points out that as the maximum phase of cold is reached snow does not continue to fall more, but less abundantly, for two reasons The atmosphere at the equator and poles, becoming colder, can take up and carry a much smaller burden of moisture; the air currents which carry moisture from equator to poles fail because the difference in temperature between equator and poles becomes less The optimum conditions for snowfall and glaciation occur at the opening and closing phases of an ice age It was at or near the beginning of the middle or cold and dry phase of the last ice age that the white race of mankind began to take possession of Europe

Our evidence is now sufficiently extensive to assure us that until the coming of the white pioneers—the Cromagnons and Předmostians—Europe had been inhabited by, and in the sole possession of, men totally unlike any race now living—men of the Neanderthal type The increasing severity of climatic conditions in the opening phase of the ice age may have pushed Neanderthal man towards extinction, but the climatic change cannot be held accountable for his complete disappearance, for many lived in Spain, southern France, and Italy beyond the range of arctic conditions When we look at the forerunners of our kind, the disappearance of Neanderthal man can be understood

Until recently our knowledge of the early colonists of Europe was founded on discoveries made in the caves of central and southern France That was because French archæologists had moved ahead of their brethren in other countries It was thus we came to know of the tall, big-headed, strong Cromagnon people, they were cavemen Even in France, however, people at this early period camped in the open, at Solutré a great field station has been explored, the fossil remains of the people have been discovered there, and their hunting mode of life determined Recently Moravia—now a province of Czechoslovakia—has begun to rival France in the contributions she is making to our knowledge of the early white or Caucasian settlers In the middle—or cold and dry—phase of the ice age, large parts of Moravia became gradually covered over by drifts of loess—a fine earth The loess drifted over the open camps of the mammoth hunters, burying their hearths, refuse heaps, utensils, weapons, ornaments, and works of art where they are now preserved deeply buried under many feet of loess Dr D K Absolon, curator of the Government Museum at Brünn (Brno), has recently explored by trial shafts such an ancient camp near Wisternitz (Vestonice), and finds that it extends over hundreds of acres Brunn itself is built over several such stations, the grave of an old mammoth hunter was found deep beneath one of its main streets Two years ago, when the foundations of a house were being dug in the suburb,

the grave of a woman of the same early period was opened

The most famous, however, of the open stations in Moravia lies at Předmost on the eastern side of the province Although this station has been known for fifty years, its extent is only now being revealed along the sides of trenches cut in the loess by a brickmaking company It was in the loess at Předmost that the late Prof Maska discovered the tomb of the mammoth hunters, in which lay the remains of twenty individuals—men, women, and children—the earliest family or common tomb known Although this discovery was made more than thirty years ago, it is only now that anthropologists have had an opportunity of determining the racial characters of the people buried in the tomb For this opportunity they are indebted to Dr Absolon, who has distributed exact casts, not only of the skulls of the mammoth hunters but also 'brain casts' taken from the interior of the skulls The brains of the mammoth hunters, even when measured on our modern standard for Europeans, were large and richly convoluted These Předmostians were not tall like the Cromagnons of southern France, but short and stout, and like the Cromagnons they were big headed, strong jawed, and of muscular build The physical differences which distinguish the Předmostians from the Cromagnons are of a local nature—such as distinguish the tall Gallowegian Scots from the shorter people of Kent

Anthropologists have been strangely chary in applying a racial label to those early invaders of Europe—the Cromagnons and Předmostians When we look round the world—ancient as well as modern —for their nearest of kin, it is not in Africa, Australia, or in further Asia that we find them In all their characters they are Europeans or proto Europeans They differ from modern Europeans chiefly in size of jaw and the robust development of face, and of thigh bone Dr Absolon believes the Předmostians must have come from Asia, their culture appears to have been derived from there It is likely we shall also trace the Cromagnons to Asia, but there are many who believe that the weight of evidence favours North Africa as their homeland The Cromagnon people became modified in Europe, but their cradle of evolution lies elsewhere Since the time these settlers brought the Aurignacian culture to Europe there have been many invasions, but it is quite possible that Cromagnon and Předmost blood may flow in the veins of men and women still alive in Europe

When we follow, by means of dated burials, the history of Europeans through the third phase of the last ice age—we find food for reflection In the rigours of the last phase tallness disappeared, but the people remained muscular and big headed They lived under such conditions as the modern Eskimo live, and their jaws and certain other parts of the skull took on an Eskimo strength of development Under this mask, however, in nose, forehead, chin, and face can be seen the essential marks of the Caucasian Later still, when modern climatic conditions were dawning, which on the reliable data provided by Swedish geologists, we may suppose to have happened 10,000 or 12,000 years ago, the physique of Europeans became more reduced There were, so far as we know, no tall people in Europe then, big heads and strong jaws had become uncommon The people became small in body with slender bones, but whether these Europeans, which saw the dawn of our present climatic conditions, were the degenerate descendants of the great pioneers—which seems to me not unlikely—or were new invaders, we cannot yet say It is just when glacial conditions were giving way to more temperate times that our knowledge of our European ancestors becomes most deficient

The Ancient Inhabitants of Palestine

An account may now be given of the men and women whose fossil remains have been discovered in cave deposits of Palestine In 1925 the British School of Archæology opened a new chapter in our knowledge of the ancient inhabitants of the East In that year Mr Turville Petre, while excavating a cave on the western shores of Lake Galilee, on behalf of the School, discovered a deep and intact stratum containing objects of that very ancient stone culture —the Mousterian—which in Europe is always associated with Neanderthal man Mr Turville Petre found in this stratum part of a human skull which was Neanderthal in type, thus proving that Palestine, at a remote period, had been inhabited by men of the Neanderthal type, and that, as in Europe, their culture was Mousterian In a neighbouring Galilean cave he found stone cultures which correspond to those which succeed the Mousterian in Europe, but as no human remains were present it was impossible for him to determine whether in Palestine as in Europe there had been a sudden replacement of Neanderthalians by men of the modern (neanthropic) type

Three years later (1928) this blank in our knowledge was made good by Miss Dorothy Garrod On behalf of the British School of Archæology she began the exploration of a cave situated at Shukbah

on the western slopes of the Judæan hills, about midway between Joppa and Jerusalem In the deepest part of the cave she found—as Mr Turville Petre had done in the Galilean cave—a Mousterian stratum, and fortunately this stratum contained heavily fossilised fragments of human bones These were submitted to me, and I was able to confirm their identification as parts of Neanderthal man The overlying strata contained a stone culture known as upper or late Capsian, a culture which corresponds with the later Aurignacian of Europe In the Capsian deposits were remains which represented about two score of people of the modern or neanthropic type—men, women, and children Thus was proved that in Palestine as in Europe there was, in later Pleistocene times, a replacement of both race and culture

In the spring of 1929 it became necessary to explore a large cave in the western flank of Mount Carmel, as it was then proposed to open a quarry at its site The Director of Antiquities for the Government of Palestine made preliminary excavations and was rewarded by rich archæological discoveries He requested the British School of Archæology to undertake the exploration of the Carmelite cave—one of very great size Miss Garrod, although she had not completed the exploration of Shukbah, took charge on behalf of the School, and pitched her camp on the plain of Sharon just under the western flank of Mount Carmel In her hands the cave is proving to be a vast archæological treasure house Palæolithic implements occur in thousands, there are carvings and other works of primitive art There is a succession of well-marked strata indicating that the cave was inhabited by man at various periods of the Pleistocene period The deepest stratum is Mousterian, that as yet remains unexplored Over it came strata containing a succession of Aurignacian cultures (middle Aurignacian and later) Then follow deposits containing cultures which mark the end of the Palæolithic period Nowhere in the strata was there any trace of pottery, or any suggestion of agriculture The inhabitants lived on the natural produce of valley, plain, and shore—which is but three miles distant

In this Carmelite cave almost every stratum contained human fossil bones—sometimes mere fragments, at other times almost complete skeletons A full report on the human remains cannot be prepared for the School of Archæology until Miss Garrod has completed her labours at Mount Carmel and Shukbah A preliminary examination, however, makes quite clear that these Aurignacian inhabitants of Palestine were neither Jews nor Arabs They were a small sized people, with short faces, long heads, very different from the tall, strong Cromagnon people of France—their contemporaries Their faces were short and their noses were low-bridged and flat, with a distinct suggestion of African origin in them Indeed their derivation from North Africa—or an affinity with the people who occupied Algiers and Tunis in Capsian times—must be considered French archæologists have observed that the ancient Capsian people of North Africa had the custom of extracting one or both of the upper central incisor teeth in youth The cave people of Palestine had the same practice—one which is continued to day by many negro tribes of Africa Yet the early Palestinians were in no sense negroes, the proportions of their limbs are European, not negroid Nor in shape of skull are they negroid—only in the conformation of nose and face Nor does there seem to have been with the succession of cultures any decided change in race, the same small people appear to persist throughout the later cave periods

In the competition to uncover the beginnings of modern civilisation, Palestine has been outstripped by surrounding countries—Egypt, Mesopotamia, and Crete But where their records leave off those of Palestine begin and carry human history into a very remote past In Biblical times Palestine was the pawn of her mighty neighbours Miss Garrod's researches reveal her, even in Pleistocene times, as the scene of contending northern and southern forms of culture

The Prehistoric Races of Africa

At the present time there are being exhibited in the Museum of the Royal College of Surgeons, Lincoln's Inn Fields, the fossilised remains of three ancient types of Africans One of these is the complete skeleton of a man found in the deepest stratum of a cave in the Rift Valley, Kenya Colony, by the East African Archæological Expedition, under the leadership of Mr L S B Leakey Not only are the stone implements shaped by this ancient Kenyan race similar to those wrought by the earliest Cromagnon people of Europe, but there are certain points of resemblance to be seen in the fossil skeleton from the Rift Valley and the tall Cromagnon people of prehistoric France The second specimen on exhibition is an intact skull, in a perfectly fossilised state, which represents a remarkable stage in the evolution of the Bushmen of South Africa For the opportunity of exhibiting this skull in England for the benefit

of students of ancient man the College of Surgeons is indebted to its discoverer, Mr B Peers of South Africa In everyday life Mr Peers is a railway porter, but in his leisure time he is a highly skilled cave explorer Recently, assisted by his son, Mr Peers completed the excavation of a vast cave near Fish Hoek, fifteen miles south of Cape Town, at a depth of ten feet in an undisturbed stratum containing a Palæolithic culture, known to South African archæologists as 'Still Bay', the fossilised skeleton of Fish Hoek man was found The third exhibit, also a fossil skull, was sent home on loan by its discoverer—Prof M R Drennan of the University of Cape Town It represents an 'Australoid' type of man which appeared early in South Africa [2]

Archæologists are now searching all parts of the world to ascertain the country which gave early Europe her Cromagnon pioneers and the stone culture they brought with them—the Aurignacian The discoveries made by the East African expedition under Mr Leakey had an important bearing on this search The culture of the ancient Kenyans —men of the Elmenteita type—had so many points of correspondence with that of the Cromagnon people of France that one must presume extensive borrowings or a derivation from a common source In Cromagnon times the Sahara was not a desert, and Mr Leakey favours the idea that North Africa may have been the homeland we are in search of There is a certain resemblance between the Cromagnon and ancient Kenyan types Both were tall, with long heads and big brains But in the fossil type of Kenya we recognise distinctly African traits in the proportions of limbs and in the structural details of face and head

The ancient Kenyans were certainly not negroes, but in my opinion represent an early Hamitic type * If we suppose these people to have come from northern Africa, then we must also presume that there has been, since their arrival in Kenya, an enormous expansion of Negro peoples, for all the lands between Kenya and Khartoum are occupied by Negro tribes On the other hand, if we follow the trail of Hamitic man as seen in the modern races of Africa, we are guided towards the Straits of Bab-el Mandeb and Arabia In Aurignacian times, Arabia and the deserts of south west Asia were fertile, and it is to these parts of Asia that I looked for the discovery of a source from which both Europe and Africa derived a community of culture and of physical traits

* Mr Leakey dissents from the opinion expressed here He regards Elmenteita man as racially akin to the Combe Capelle and Grimaldi people of Europe.

One of the chief results which have issued from Mr Leakey's researches in Kenya Colony is to give archæologists a time scale for measuring the prehistoric events of Africa His evidence favours the belief—if it does not prove it—that the Elmenteitans of Kenya were the contemporaries of the earliest Cromagnons of France His time scale has given us a clue to the date of other fossil human remains which have been discovered in Africa In 1913 a skeleton was found by Dr Reck at Oldoway, in what is now Tanganyika Territory, embedded in a pleistocene deposit There can be no doubt that the Oldoway man is of the same type as Mr Leakey's ancient Kenyans and belongs to the same period of time Last year the fossil skeleton of a man, described by Dr R Broom,[3] was discovered within a Pleistocene deposit in the northern Transvaal It is probable that the Australoid type now exhibited and described by Prof Drennan may prove to be an offshoot of the same stock The Bantu peoples of Africa have spread into South Africa in comparatively recent centuries, there seems to have been a similar migration of a proto Hamitic people in Pleistocene times

Our search into the prehistory of man is bringing to light strange and unexpected things One of these is the great development of body and brain in the early Palæolithic hunters—the ancestors of the men who brought in the last stone age and the beginnings of our modern civilisation At first sight one is apt to ascribe our modern falling away in size of jaw and brain to the effects of city civilisation That this is not the whole cause is proved by Mr Peers's discovery of the ancestor of the Bushmen of South Africa Modern Bushmen still retain the wild, hunting mode of living Yet their jaws and faces have undergone the same reduction as are seen when we compare the skulls of modern Europeans with those of the ancient Cromagnons The ancestral Bushmen from the Fish Hoek cave had, like the Cromagnon people, an exceptionally large brain—fifteen per cent more than is usual in modern Bushmen The proportion between the face and the brain containing part of the head in the ancestral Bushman was that which is seen in modern children at the age of eight or ten years—where the face is small in proportion to the size of head This is so in all dwarf races of mankind—to which racial category Bushmen belong Prof Drennan, who has published a preliminary account of the Fish Hoek skull, applies to its explanation a law which is gaining assent from anthropologists, namely, that the retention of infantile and youthful traits plays a part in the

evolution of new human races—particularly of the dwarf races of mankind In their structural make-up Bushmen show a strange mixture of prehistoric and ultra-modern traits

The Significance of Peking Man

European anatomists are now in a position to appraise the significance of the fossil remains of man discovered in cave deposits at Chou Kou Tien, 37 miles to the south-west of Peking Prof Davidson Black had placed at their disposal full details of his discoveries, and an examination of the evidence submitted leaves no doubt that China has made a contribution of the highest importance to our knowledge of the evolution of men The discovery has a threefold interest first because of the part of the world in which it has been made Of the prehistoric human types which inhabited the vast continent of Asia we knew nothing until now Secondly, the discovery is important because it gives us the evolutionary stage reached by the ancient Asiatics at a time which is critical in the evolution of humanity—the beginning of the Pleistocene period, the geological period which preceded the dawn of our modern world Former finds had made us acquainted with three beings who belong to this early period—the Java man (*Pithecanthropus*), Piltdown man (*Eoanthropus*), and Heidelberg man (*Palæoanthropus*) Now we have a fourth—Peking man (*Sinanthropus*)—from the distant part of another continent The closest relationship of this new arrival lies with Java man, but it has also resemblances to the pre Neanderthal type of Europe represented by Heidelberg man

The third aspect of this new discovery is the scientific manner in which it has been carried out The most up to date and exact methods have been applied It has been made by a highly skilled band of men enrolled from various nationalities The anatomist, Prof Davidson Black, is a Canadian and a distinguished representative of the British school of anatomy, the geologist and discoverer of the site is Dr J G Andersson, a Swede, the archæologist, Father Teilhard, is French, the director of excavations, Mr W C Pei, is a Chinaman—a member of the Geological Survey of China A system of scientific co-operation has given full, precise, and reliable facts concerning the nature of Peking man and of the times in which he lived

When human remains are found in a natural deposit, disputes are apt to arise as to its geological age It is therefore fortunate that Dr Anderson had dated the geological deposits at Chou Kou Tien before the first trace of man was found, and although at first he was inclined to regard them of late Pliocene age, yet a fuller study of the animal fossils, particularly the fact that the three-toed horse had disappeared and been replaced by the one-toed form, led him to assign the deposits—laid down in limestone caves and fissures at Chou Kou Tien—to an early part of the Pleistocene period—a conclusion confirmed by all later observations Thus we can safely regard Peking man—known to the scientific world as *Sinanthropus pekinensis*—as representing the evolutionary stage reached by the inhabitants of the eastern part of the Old World at the beginning of the Pleistocene period In the cave strata which yielded the human remains no hearths were traced, no sign of fire seen, and no shaped stone or bone which could be regarded as a tool found It would be unsafe to presume, on this negative evidence, that *Sinanthropus* was ignorant of fire and had not discovered the use of tools

The importance of an archæological discovery can be estimated by the extent to which it causes a re orientation of previous knowledge *Sinanthropus* can be fitted into the genealogical trees of man's descent now in common use He sprung from the main human stem near the branches which gave us Java man on one hand and Neanderthal man on the other We have, however, to alter or reconsider our ideas concerning the rate at which the human brain has evolved, or alter our estimate of the duration of the Pleistocene period In Java man the brain was just reaching the threshold of a human standard We regard 950 c c as the lowest possible limit of brain size compatible with the simplest manifestations of human mental life, the Java man was just reaching that size of brain, at the end of the Pliocene or beginning of the Pleistocene period In later Pleistocene times we find large-brained human beings—both of the Neanderthal and of the modern types of man

If we regard the Pleistocene period as having a duration of only 250,000 years, we must presume that the evolution of the human brain has been unexpectedly rapid to convert the Java brain into that of later Pleistocene man Seeing how complex and intricate an organ the human brain is, such a transformation has seemed impossible and hence Java man has come to be regarded not as an ancestral stage, but as end shoot—a survival of an earlier small brained period Now, however, comes the evidence from China In brain size Peking man resembles Java man—only a little

larger—just within the human minimum standard As Prof Davidson Black points out, there is definite evidence on the outside of the skull to make us certain that the brain had moved a stage in a more humanward direction than had that of the Java man Even if we take the highest estimates for the Pleistocene period—a duration of 1½ million years—the changes which would convert the brain of *Sinanthropus* into that of the La Chapelle man would have to be of unexpected rapidity

There is, however, another possibility The men of Java and China may not have represented the highest stage reached in human brain development in early Pleistocene times, elsewhere in the world there might have been a higher form of humanity Peking man lived at the eastern end of the Old World, his contemporary—Piltdown man—lived at the western end of it Piltdown man, in spite of his ape-like canine teeth and his simian chin, makes an infinitely closer approach to the modern type of man than does Peking man The latter has the flattened head which we knew of only in Java man, he has the great bony beam across his forehead which we meet with in Neanderthal man, and many other traits which give him a claim, as Prof Davidson Black has said, to be considered as a possible ancestor of the Neanderthal races The chin of a fossil child (*Sinanthropus*) shows a stage in the transformation of a simian into a human chin The Peking teeth have revealed a mixture of characters—some very ancient and others almost ultra modern On the other hand, Piltdown man has none of the Neanderthalian or Javanese traits, the conformation of his skull bones and of his head herald features of modern man All along I have maintained that Piltdown man was not small-brained, nor is the organisation of his brain of a lowly type Even the lowest estimates of his brain capacity—1200 c c —place him well within the modern category of brain size On the evidence as it stands, England may justly claim to have been leading the world in early Pleistocene times Piltdown man fashioned and used elaborate tools The evidence collected by Mr Reid Moir in the Pliocene deposits of East Anglia also favour England's claim to priority in the evolution of higher humanity

Preglacial Europeans

An account has already been given of the type of man who inhabited Europe before the onset of the last glacial age The fossil remains of one being of this distant period was discovered last year almost at the gates of Rome The Aniene, a stream which joins the Tiber just before that river enters modern Rome, filled its valley in Pleistocene times with deposits, which are made up of sands, clays, and also calcareous ingredients In these deposits are entombed the fossil bones of elephant, rhinoceros, hippopotamus, and horse—of kinds which lived in Italy in the temperate times which preceded the last great period of glaciation In the Aniene deposits are found ancient types of stone implements Six Mousterian stations have been mapped out within 10 miles of Rome, and although it was suspected they were the work of Neanderthal man, not a bone of that fossil type had been found in Italy until May 1929 In that month a labourer digging in a gravel pit in the lower valley of the Aniene, and working at a stratum which lies 20 feet below the present surface level, uncovered a calcareous mass in which was embedded a human skull

Prof Sergio Sergi, director of the Anthropological Institute of the University of Rome, has published a preliminary account of the skull and finds that it is altogether different from that of modern man and is of the Neanderthal type [4] From the photographs of the skull—still partly embedded in its hard matrix—one can see that it is almost a duplicate of the Gibraltar skull discovered in 1848 Like the Gibraltar skull, the specimen now discovered in suburban Rome—the Aniene skull—is that of a woman, both are alike in being small brained—less than 1200 c c —the smallest headed of all known fossil skulls of the Neanderthal type Both have the same long gorilline faces, capacious noses, and strong bony torus above the eye sockets

The Aniene skull is of the same age as the stratum in which it was entombed, and the geological evidence definitely assigns the deposition of the stratum to the long temperate period which preceded the last glaciation Thus Italian anthropologists have proved that in their country, as in France, the Mousterian culture represents the handiwork of Neanderthal man, and that before the last ice age the valley of the Tiber, the site of Rome—and in all likelihood the whole of Italy—was inhabited by human beings of the Neanderthal species The earliest arrivals in Italy of Neanthropic or modern type of man have not yet been found

More instructive still are the German discoveries made in the valley of the Ilm, just above Weimar—the home of Goethe The ancient valley of the Ilm had become filled by deposits, but in a manner quite different from that which produced the Aniene formations The ancient valley of the Ilm had

steep cliff like sides and a flat meadow-covered floor From the sides of the valley issued springs charged with calcareous salts which were slowly deposited as the issuing streams flowed across the flat lands Thus were slowly laid down a series of strata which gradually filled the valley—in some places to a depth of 60 feet The series of strata finish off in the glacial period , they began to form early in the previous interglacial period

These Pleistocene deposits—or rocks—are now worked for building and other purposes , several quarries have been opened in the vicinity of Weimar —at Taubach and at Ehringsdorf The deeper strata, laid down in the temperate period, have yielded many fossil bones of extinct animals, traces of hearths and stone implements of a crude pre-Mousterian kind of workmanship So early as 1895 two teeth were found—at first attributed to an extinct anthropoid ape—but now known to be human In 1914 a lower human jaw was found in the deepest fossiliferous stratum, and then in 1916 that of a child Later, in the autumn of 1925—just before the International Association of Palæontologists visited the pit at Ehringsdorf—a block of rock was blasted from the fossiliferous stratum—at a depth in the quarry of 54 feet—on which was exposed part of a human skull The work of disentangling the skull and its reconstruction proved laborious, so that it was not until late in 1928 that a description of it was published—by Prof F Weidenreich of the University of Heidelberg [5] The skull represents a preglacial inhabitant of Germany The skull—that of a young person—is most capacious, and although possessing the hallmarks of the Neanderthal species, yet differs in several important respects from the later representatives of that extinct race The front part of the skull was not low, but had a high vault The Ehringsdorf jaws, too, show certain primitive features Most remarkable of all is the clear evidence that severe wounds had been inflicted on the forehead of the Ehringsdorf person while the skull was still in a fresh condition The oldest known Neanderthal skull has the marks of Cain on it ! Prof Weidenreich suspects the ancient Ehringsdorf people of cannibalism

The discoveries made in the valleys of the Aniene and Ilm give us a glimpse of the people who lived in Europe during the last interglacial period , they were of the Neanderthal type When this type first appeared in Europe is an open problem , Heidelberg man, who must be attributed to a more remote period, foreshadows the features of Neanderthal man While these discoveries have extended our knowledge of the earlier phases of Neanderthal man, others, particularly that made by Miss Dorothy Garrod at Gibraltar (1925–27), are equally welcome because they throw light on his terminal period The boy whose fossil skull Miss Garrod found in the deposits of a rock shelter on the north front of Gibraltar, although only five years of age, was particularly large brained , if he had lived and his brain had grown at the same rate as in a modern boy, it would have been larger than that of the most capacious Neanderthal skull known The Neanderthal race did not perish for lack of brains

One other important discovery of the fossil remains of man has been made in recent years—one which carries the distribution of the race as far east as the Crimea At a Mousterian site, some fifty miles to the north-east of Sebastopol, Dr Bontch-Osmolooski, Conservator of the Russian Museum, Leningrad, uncovered a fossil skeleton of Neanderthal man A full account of this discovery has not yet been published, but the remains have been examined by Prof Boule of Paris—the leading authority on such matters—and he has confirmed their Neanderthal nature On the other hand, the fossil skeleton unearthed at Podkoumak—north of the Caucasus and to the west of the Caspian—although claimed by its discoverer as being those of Neanderthal man, are certainly not so The jaws and teeth are marked by all the traits of modern man [6]

The present state of our knowledge regarding Neanderthal man is this His remains have been found from Weimar in the north to Malta in the south, from Jersey in the west to the Crimea and Palestine in the east There were local breeds or races In point of time, some of the remains go back to an early phase in the last interglacial period , others are attributed to the first phase of the last glaciation There is evidence that for a long part of the Pleistocene period all the inhabitants of Europe were members of this peculiar Neanderthal race Did they become transformed into modern man or did the race die completely out ? In his Huxley Lecture (1928) Dr Aleš Hrdlička put forward the case for transformation, and some of his arguments have still to be met It seems to me more likely that Neanderthal man and modern man stand to each other not as father and son but as cousins No skull has ever been found which in my opinion can be regarded as transitional or as showing a mixture of characters due to hybridisation of Neanderthal man with modern man No trace of Neanderthal man has been found in any deposit later than those which are marked by the Mousterian culture The termination of the race, in my opinion, was clean cut—such as we meet with when one race rapidly replaces another Where the replacing races came from—the Cromagnons and the Předmostians—certainly remains an unsolved problem, but such evidence as there is seems to trace the first arrivals of Neanthropic man in Europe from Asia rather than from Africa

old style of polar exploring in naval vessels under officers ordered to carry out a plan devised by others Since the *Fram*, the best polar work has been done by small parties of trained and well equipped men under a leader following out his own plans by his own methods It is doubtful, as the *Karluk* and the *Maud* have shown, whether Nansen's theory of the ice drift on the Polar Sea is correct, but it was the faith of the man that made him great, not the particular object of his belief

With the present century, Nansen began a series of oceanographical expeditions in the research steamers of the Norwegian Government and some times in his own yacht, during which he attacked special problems of oceanic circulation He took a leading part in the foundation of the International Council for the Study of the Sea in 1900 in co-operation with Sir John Murray When the Council was established, Nansen stood out for having the central laboratory in Norway, and it was sometimes no easy matter to secure smooth working when his views differed sharply from those of other delegates He was always so absolutely certain of the correctness of his own opinions that at times he did rather less than justice to his opponents, but even when argument only stiffened his opposition an appeal to his good nature often brought about a conciliatory compromise

There was in Nansen a singularly engaging *naïveté*, an example of which impressed me so greatly that the spot in Camden Road where he said it remains photographed on my mind "You know," he said, "people say that I am very difficult to get on with, it's quite a mistake, only give me my own way and I'm the easiest fellow in the world to get on with"

While keeping the Norwegian share to the front at the Council meetings Nansen was doing his utmost, in co-operation with Helland Hansen and Hjort, to establish Norwegian supremacy in oceanographical research, and extremely important advances have been made by them in the construction and use of apparatus and in the interpretation of the observations bearing on the circulation of the Norwegian Sea and the North Atlantic as a whole

The political aspirations of his grandfather were rekindled in Nansen's mind when the question of separate consular representation for Norway threatened the union with Sweden, and had personal ambition been a leading motive in him his popularity was such that he could easily have made himself a dictator or a president But he was ambitious only to secure a separate standing for his country, and the peaceful revolution which gave Norway a king of its own was largely Nansen's work He would not enter into contentious politics at home, but took a pride in being the first Norwegian Minister to the Court of St James's, a post he accepted from a sense of duty to his own people, and, despite his appreciation of the personal friendship of King Edward, he resigned with relief as soon as he felt that the new kingdom was fairly on its feet He never cared for ceremony or formality of any kind, and he went back quietly to his professorship of oceanography and to the joy of research in the open sea

Nansen was attracted to the earliest history of the Arctic Seas and sought to link the Vinland of the Sagas with the Fortunate Isles of classic legend, finding satisfaction for the weird and wistful cravings of his mind in blurred legends which he strove, with only partial success, to elucidate in his historical work "In Northern Mists"

For a second time Nansen passed through the Kara Sea, and in a mission for the Russian Government travelled the length and breadth of Siberia in order to report on its resources Then came the War, and the plight of Norway as a helpless neutral, with its shipping paralysed, brought him back to the service of his country as president of the Norwegian Union of Defence In 1917 he went to America and secured by his personal influence an arrangement between Norway and the United States that saved his country from economic strangulation When the War was over, he became one of Norway's representatives on the League of Nations, and all his greatness of heart and mind was thrown into the herculean task of repatriating prisoners of war, many of whom were lost in Russia, saving the remnants of Armenian communities from extermination, organising food supplies for the starving millions of eastern Europe, and using his unrivalled personal popularity as an instrument for fighting the worst evils arising from the War The Nobel Peace Prize was never more worthily bestowed than when Nansen got it in 1923

In 1925 he was elected Lord Rector by the students of St Andrews, and in the following year he gave them a rousing rectorial address, in which he showed them how the spirit of adventure had been the unifying principle of his own life, inspiring his early explorations, his mature researches and the philanthropic missions in which he wore out the last of his tremendous strength He said

"It is our perpetual yearning to overcome difficulties and dangers, to see the hidden things, to penetrate into the regions outside our beaten track, it is the *call of the unknown*, the longing for the Land of Beyond, the divine force deeply rooted in the soul of men which drove the first hunters out into new regions, the mainspring perhaps of our greatest actions—of winged human thought knowing no bounds to its freedom"

The old love of adventure and the passion for research rose in a last flame of enthusiasm when he planned an airship voyage across the north polar basin in the *Graf Zeppelin*, and he had arranged to give a lecture on the subject to a joint meeting of the Royal Meteorological Society and the Aeronautical Society in March last, but the fatal illness baulked his will He died at his home in Lysaker in his sixty ninth year on May 13, 1930 Had he been able to lecture in March he would have tried to convince the sceptical British men of science of the soundness of his plans as he had tried to convince the British admirals in 1893 As in that case he would probably have failed, but had he lived to return successful, the doubting meteorologists, like the doubting admirals before them,

would have been whole hearted in acknowledging that he was right Nansen knew this well, and in one of his last letters to me he wrote "I think I have had some evidence and experience as to the ability of your people to appreciate the achievements of foreigners as much as those of your own people In fact, I never felt that I was a foreigner in England or Scotland" Their sense of kinship with Nansen led his British friends to initiate the *Fram* Preservation Fund while he was still alive, and now they can think of no worthier memorial to the man in his own land than the old ship secured for ever against the tooth of time, like the *Victory* at Portsmouth HUGH ROBERT MILL

DR FRANK R BLAXALL

DR F R BLAXALL, who died on May 24 after a brief illness, was bacteriologist to the Vaccine Department of the Ministry of Health, a post he had held for just over thirty years He established the Government Lymph Institute at Hendon and was responsible during this period for the preparation of the vaccine lymph issued by the Government, and the high reputation which this product deservedly enjoys is largely due to his care and painstaking work

Blaxall received his medical education at University College and Hospital, and obtained his M D (Lond) degree in 1890 with honours in medicine After holding several resident hospital posts, he was appointed lecturer in bacteriology at Westminster Hospital Medical School and in 1896, in collaboration with Dr Colcott Fox, published an important paper on ringworm in London He now came under the influence of the late Sir Armand Ruffer and Prof Allan Macfadyen at the British (now Lister) Institute of Preventive Medicine, and at its old headquarters in Great Russell Street investigated the bacteriology of rheumatoid arthritis, and with Macfadyen published a paper on the thermophilic bacteria—one of the early contributions to this subject In 1896 he commenced an investigation with Dr Monckton Copeman on the inhibitory action of glycerin upon the adventitious micro organisms present in calf lymph, and their results were communicated to the Local Government Board and to the Royal Commission on Vaccination then sitting, the outcome of this work being Blaxall's appointment as bacteriologist to the Vaccine Establishment, then in Lamb's Conduit Street

From thence onwards, Blaxall's work was mainly concentrated upon vaccine lymph, and he published papers on the preparation of calf lymph and on the sterilising action of glycerin and of oil of cloves upon the adventitious microorganisms of vaccine lymph, respecting which he became a recognised authority He served as a member of the Smallpox and Vaccination Commission of the Health Committee of the League of Nations and of the Departmental Committee on Vaccination To lifelong friends and colleagues, Blaxall's loss is indeed a heavy one

R T HEWLETT

WE regret to announce the following deaths

Sir Thomas Walker Arnold, C I E, professor of Arabic in the University of London, English editor of the "Encyclopaedia of Islam", on June 9, aged sixty six years

Prof J B Bradbury, for the past thirty six years Downing professor of medicine in the University of Cambridge, on June 4, aged eighty nine years

The Right Rev G F Browne, formerly Bishop of Stepney and of Bristol, sometime secretary of the Local Examination Syndicate at Cambridge and also (1887–92) Disney professor of archæology in the University, on June 1, aged ninety six years

Major Sir Aston Cooper Key, C B, formerly chief inspector of explosives at the Home Office, on May 28, aged sixty nine years

Dr Kiyoo Nakamura, honorary member of the Royal Meteorological Society, who was director of the Central Meteorological Observatory of Japan from 1895 until 1923, on Jan 3, aged seventy five years

Mr E A Sperry, inventor of the Sperry gyro compass and other gyroscopic appliances, on June 16, at sixty nine years of age

Dr G N Stewart, professor of physiology, Western Reserve University, Cleveland, Ohio, on May 28, at seventy years of age

Mr A F R Wollaston, fellow and tutor of King's College, Cambridge, who served as medical officer and naturalist to the first Mount Everest expedition under Col Howard Bury, on June 3, aged fifty five years

News and Views

SIR ARTHUR KEITH's lectures on recent discoveries of fossil men, delivered at the Royal College of Surgeons during the month of May, and published in an abridged form in this week's Supplement, are likely to provide material for argument among anthropologists for some time to come During the last decade, but especially in the last four or five years, there have been some remarkable accessions to our knowledge of early types of man Palestine, Gibraltar, South Africa, East Africa, and most recently China, each in turn has yielded to the spade new types or new variants of known types Each of these discoveries, it is safe to assume, helps us a stage on the way to final truth, but for the moment, it must be admitted, they add to the complexity of the problem which the anthropologist seeks to solve Sir Arthur Keith's lectures, in a comprehensive survey of the new material, aimed at showing how it could be adapted in building up a scheme of the origin, development, and distribution of early man One of the most interesting of recent discoveries with which he dealt—probably quite new to most of his audience —was that of the remarkable skull from Gardar in south west Greenland, for the description of which he was indebted to Dr Hansen of Copenhagen This skull is not, indeed, one of high antiquity, for it was found in association with the remains of Norsemen in a twelfth century graveyard, but whether it be regarded as atavistic, as Dr Hansen holds, or pathological as Sir Arthur Keith is inclined to think, its

remarkable character, which would place it in a class with the more primitive types of fossil men, invests it with the utmost significance morphologically irrespective of its date It is possible, as Sir Arthur said, that it reproduces a stage of man's evolution which may yet be discovered in a fossil state It is, perhaps, not inapposite to point out that the Neanderthal skull itself was once considered to be pathological

So many points of interest were raised by Sir Arthur Keith's lectures that it is difficult to single out any which call for special mention Not unnaturally his audience was anxious to hear his views on Peking man, now that more detailed information has been so generously laid before English anthropologists by their colleagues in China While his conclusions agree with those already expressed by Dr Davidson Black and Prof Elliot Smith as to the relation of Peking man with *Pithecanthropus erectus*, as he points out, the low estimate of the cranial capacity raises a serious problem as to the rate of growth in the size of the brain in the upward scale of human evolution, if, that is, the dating of Early Pleistocene is correct, as there is every reason to believe The tribute paid to the scientific accuracy with which the investigations attendant on the discovery have been carried out were no more than is deserved If we owe it to the workers in China enumerated by Sir Arthur Keith that we now know what manner of being was early man in eastern Asia, an equal debt is due to Mr Leakey for his work in East Africa which has given us Elmenteita man and to Miss Garrod who at Shukbah and Mount Carmel in Palestine has not only brought to light the most complete sequence of palæolithic cultures yet to be found in that area, but has also revealed to us the skeletal remains of the hitherto unknown people who followed upon the Neanderthal race discovered by Mr Turville Petre in 1925 The interesting inferences which Sir Arthur Keith drew from these and other discoveries upon which he touched may be left to speak for themselves It may be noted, however, how individual discoveries of recognised importance have gained in significance as they have here been brought into relation one with another Europe, once almost the only field for the investigator, no longer bounds the horizon, and the farthest corners of the earth now yield their share towards solving the problem of man's origin, growth, and distribution

ON June 26 occurs the bicentenary of the birth of the French astronomer Charles Messier, who was born in 1730 at Badonviller, in the Department of Meurthe et Moselle Like Lalande, he was attracted to astronomy by the eclipse of the sun of 1748, and at the age of twenty he went to Paris, where Delisle obtained a position for him connected with the marine He was the first in France to observe the eagerly expected comet of Halley, which he saw on Jan 21, 1759, and from that time onwards he spent most of his life searching the heavens for comets and nebulæ Louis XV called him the 'comet ferret', and after the death of Lacaille, Messier was regarded as the foremost practical astronomer in France He was elected a foreign member of the Royal Society in 1764, and obtained a seat in the Paris Academy of Sciences in 1770 He was also a member of the Academies of Berlin and St Petersburg He published a small catalogue of nebulæ in 1771 and another containing 103 entries in 1781, but his work in this direction was soon surpassed by that of Herschel

LIKE his contemporaries Messier lost his pension at the Revolution, and it was only with the assistance of Lalande he was able to continue his observations at Cluny His discovery of a comet in the constellation Serpentarius was made in September 1793 in the midst of the Reign of Terror, and it was the orbit of this comet the unfortunate Bochart de Saron calculated a few days before his death After the Revolution Messier was given a seat in the Institute, and became a member of the Bureau des Longitudes In his eighty sixth year he was attacked by paralysis, and he died in Paris on April 11, 1817, having been blind for some time

STANDARDISATION, however undesirable in some spheres of human activity, has manifest advantages when applied to industrial processes and products A conference which was recently held to examine the requirements of the chemical industries in respect of the formation of a British chemical standardising body, which would do for chemistry what the British Engineering Standards Association is doing for engineering, found itself unanimous in the opinion that such a body should be constituted It cannot be denied that standardisation plays a very important part in securing industrial efficiency and economy, and is, in fact, an essential feature in the rationalisation of industry Even standardisation may be standardised and the view is crystallising that there should be a single organisation embracing all forms In the British Engineering Standards Association there are twelve sections representing different industries, each section enjoying entire autonomy under a central Council within the terms of the charter It has been proposed that the chemical industries should make use of the organisation which already exists, and steps have been taken to change its title to 'The British Standards Association', so that it may be in a position to embrace all forms of standardisation The conference of representatives of organisations connected with chemistry, and of industries utilising chemistry, shares the view that a single organisation is desirable, and has agreed to the appointment of a committee to explore the situation as regards chemical standardisation in collaboration with the British Engineering Standards Association

THE first complete technical account of the notable German Atlantic liner *Bremen* was published on May 24 in a special issue of the *Zeitschrift des Vereines Deutscher Ingenieure*, and from this the *Engineer* is publishing an account of her propelling machinery The first part appeared in the issue for May 30 The *Bremen* has twenty water tube boilers, eleven of which are double ended, delivering steam at 327 lb pressure, absolute, superheated to 350° C The boilers are oil-fired and at sea, for the main and auxiliary machinery,

about 500 tons of steam per hour are required The vessel carries about 1600 tons of oil fuel in her double bottoms and side bunkers The main machinery consists of four sets of turbines, each consisting of a high pressure or intermediate pressure and low pressure turbine driving the four shafts through single reduction gearing The speed of the turbines is 1800 r p m, that of the propellers 180 r p m The total power developed is 92,500 S H P Designed to have a gross tonnage of 51,656 tons and a service speed of 26 25 knots, the *Bremen* has accommodation for 2200 passengers and a crew of 1000

We have received from the Institution of Electrical Engineers a revised supplement of the Institution's wiring regulations, which refers specially to the use of radio receiving sets connected with the public supply mains Copies of these revised regulations can be obtained free of charge from the secretary of the Institution, Savoy Place, W C 2 Emphasis is laid on the danger arising to the ordinary user when an ordinary 'all electric' set can be opened when still connected with the mains, thus exposing 'live' metal When valves have to be inspected or changed, the apparatus should always be previously disconnected from both poles of the supply system Manufacturers ought always to attach a notice to this effect to the case containing the radio apparatus It is not safe to asume that the neutral conductor of a three wire direct current system is always at zero potential Should a fault develop in a main or should a circuit breaker in the link connecting the neutral conductor to earth be opened for testing purposes, there may be a potential difference of 200 volts between all the neutral system and earth The full voltage of the station, between 400 and 500 volts, may also exist between earth and those conductors which normally operate at about 200 volts above or below earth When using crystal sets it is important to keep all the wires of the set well away from any metal objects which might conceivably become alive from contact with the mains The covers of metal switches used for lighting have been known to become alive If there is no risk of the cover making contact through the body with a good earth, the chance of getting a shock is negligible and the fault may never be discovered When, however, a good earth is brought near the cover, there is a real risk of shock

In his Friday evening discourse on unemployment, delivered at the Royal Institution on June 13, Prof Henry Clay said that it is obvious that the interruption and dislocation of established economic relations by the War must affect Great Britain, with its immense international trade, more than any other country The artificial prosperity produced by inflation between 1915 and 1920 also deferred any attempt to make adjustment to conditions that would have changed even if there had been no war, such as the discovery of methods of economising in the use of coal, or the growth of competition in the low-wage eastern countries in the textile industries Three [illegible] can be distinguished as hampering industrialists in their efforts to restore activity First, the fall in world prices, the chief burden of which falls upon the directors and owners of businesses, on whom society relies for initiative and expansion In the second place, the economic system has become more rigid while wholesale prices have fallen 25 per cent since 1924, wage-rates have fallen only 1 or 2 per cent, and Government charges had increased In the third place, the chief fund which fed the growth of industrial enterprise in new directions, and so provided expansion that compensated for lost and declining industries, the profit retained in the business by successful concerns, is now curtailed by high direct taxation Before the War, of every pound applied to the development of industry by the management which had proved its capacity to develop by earning profit, only a shilling or so was taken by the State, now a quarter or a third is taken out of a diminished total The proceeds of this taxation go to pay interest on debt and to finance social services, in this transfer of income from financing industrial development to financing consumption may be found, in part at any rate, an explanation of the activity of the luxury trades in a prolonged period of extreme trade depression

Among the communications made to the Czech Academy of Science in 1927, and now recently published in the *Bulletin International* for that year, is one from Prof Karel Domin dealing with the geology and natural history of the primeval woodlands of Boubín in the Šumava (Bohemian Forest mountains) This virgin forest is a classical region for the study of hercynian vegetation, having remained untouched for a very long period The principal trees are the fir, beech, spruce, and, to a less extent, the maple There is abundant herbaceous undergrowth, especially on the northern and marshy side In the drier part, where deciduous trees predominate, a thick layer of friable humus has formed A characteristic feature of the forest is the presence of spruces with stilt-like roots which have arisen partly through the growth of young plants on the trunks of dead conifers which have subsequently decomposed and partly by the falling away of the soil This is well shown by Prof Domin's set of photogravures illustrating the text A comprehensive list of the flora is given, and it is shown how four distinct types may readily be delimited These are (*a*) marshes and swamps, (*b*) quagmires and damp places in the forest, (*c*) places of medium humidity, and (*d*) alpine and rocky parts All are relatively rich in characteristic vegetation The animal life, however, is to day relatively poor The same issue of the *Bulletin*, which covers the natural and mathematical sciences and medicine, also contains an account of the geology of the Dalmatian island of Silba, by Dr O Matoušek, Prof V Posejpal's recent studies on fluorescence, some further work with the aid of the dropping mercury cathode by Prof J Heyrovský and his students, as well as several biological and histological contributions with illustrations in colours

The second Annual Report of the National Museum of Canada, although its title states that it is 'for 1927', covers the period from April 1, 1927, to

Mar 31, 1928, and was published towards the end of 1929 It indicates that good progress is being made with the various exhibition series of specimens, anthropological, botanical, zoological, and geological, in the Victoria Memorial Museum in Ottawa to which the museum was transferred in 1920 But the space available for the exhibition of collections obviously falls far short of what is necessary, and compares unfavourably with the extent of such provincial museums as that of Ontario The Director estimates that the present building must be increased by more than half as much again, at a cost of nearly a million dollars, to meet the requirements of the next twenty years or so A substantial amount of field work was carried out by the various departments during the period reviewed, perhaps the most important of which, since opportunities become rarer, being the collection of 137 Niska songs, recorded in text form and on the phonograph, and the collection of two adult bulls of the wood buffalo Of the 107 pages of the Report, 72 contain papers of ethnographical and zoological interest, the most unusual being an account of the materia medica, botanical and zoological, of the Bella Coola and other tribes of British Columbia, slugs, we note, should be opened and applied over large cuts, and a draught of a decoction of sea cucumber is a specific against heartburn

THE British Golf Unions Joint Advisory Committee has issued a further interesting number of the *Journal of the Board of Greenkeeping Research* Although the Research Station at St Ives, Bingley, Yorks, has been in existence for less than one year, it has become more and more apparent that its establishment has been fully justified, judging from the rapid growth in the demand for its services Owing to the large amount of advisory work that is necessarily an important feature of the station, it has hitherto been impossible for the present staff to carry out as much actual research work as is desired, and this fundamentally important part of the work can only be developed if the increased interest is accompanied by greater financial support However, much progress has already been made, a number of experimental plots having been laid down and a nursery for stolon production established One of the chief items in the present issue of the *Journal* deals with measures for eradicating worms, details of practical experience being supplied by various golf clubs An account is also given of the formation of putting green turf by vegetative means, use being made of those species of grass which naturally form runners or stolons The action of iron and ammonium sulphates on both grasses and weeds is the subject of a further article One section of the *Journal* is devoted to the publication of typical inquiries and their respective replies This is to be a permanent feature and should do much towards promoting interest and spreading authoritative information on the various problems of greenkeeping

THE ultimate justification of the Empire Cotton Growing Corporation lies in the success it achieves in securing an increase in the production of Empire grown cotton, and in its report for 1930 it is able to show a fivefold increase to 466,544 bales The work of its officers in the various cotton-growing territories is briefly reviewed, but, as this forms the subject of a separate publication (see NATURE, April 12, p 553), the main interest of the present report centres in other subjects, and especially in the work of the Corporation's research station in Trinidad This station was established to prosecute fundamental research " even if its objects might appear to be remote from immediate practical application " Research papers from the station have appeared in the *Annals of Botany* and are republished in the form of *Memoirs* issued by the Corporation Evidence is repeatedly given throughout the report of the difficulty of limiting the field of inquiry to the narrow scope of cotton Sound agricultural practice inevitably involves rotations, and investigations have to be extended to other fields Thus in South Africa it is noted that more attention has been devoted to " the important question of rotation crops " Again, it is useless to produce a crop if the produce cannot be marketed The pioneer work of the Corporation in mechanical transport is now being continued by the Oversea Mechanical Transport Directing Committee, but contact is maintained through the director of the Corporation, who is chairman of that Committee

THE Report for the year 1929 of the National Physical Laboratory is a quarto volume of 300 pages, 230 of which are devoted to particulars of the researches carried out in the physics, electricity, metrology, engineering, aerodynamics, metallurgy, and Froud tank departments respectively The amount of work done for industrial firms exceeds that in any previous year, while the research carried out for boards and committees of the Department of Scientific and Industrial Research which has a direct bearing on industry has been maintained Materials for high pressure steam turbines, for aeroplane engines, for motor springs and chains, and lubricating oils have all been under investigation A new building for the Physics Department is nearing completion and the construction of a compressed air tunnel is about to be commenced New buildings for acoustics and for photometry are under contemplation, as well as a number of smaller additions rendered necessary by the increase of the demand for work by industrial firms Nearly ninety official and twenty unofficial papers have been published by the staff in scientific and technical periodicals during the year, an output which affords ample evidence of their activity

THE complete annual report of the Board of Regents of the Smithsonian Institution for the year ending June 30, 1928, has recently been issued This volume, as is customary, includes a complete statement of the activities of the Institution, and in addition, a valuable appendix occupying 585 pages or about four fifths of the volume, containing articles by authorities on scientific topics of current interest Some of these are reprints of addresses which have already appeared in whole or in part in our columns, for example, Sir James Jeans's Trueman Wood Lecture before the Royal Society of Arts on " The Wider Aspects of Cosmogony ", the British Associa-

tion address at Leeds by Prof R A Millikan, which appeared as a supplement to NATURE entitled "New Results on Cosmic Rays", by Prof R A Millikan and Dr G H Cameron, Dr R N Rudmose Brown's presidential address at Leeds to Section E (Geography) of the British Association on "Some Problems of Polar Geography" There are also contributions by Prof J W Gregory on "Water Divining", being his presidential address in 1927 to the British Water works Association, Public Works, Roads, and Transport Congress, and the Arrhenius Memorial Lecture delivered before the Chemical Society by Sir James Walker on May 10, 1928

VOLUME 18 of the Travaux et Mémoires of the Bureau International des Poids et Mesures (Paris Gauthier Villars et Cie, 1930) contains nearly 300 pages and gives accounts of the meetings of the international committee since 1921 The director, M Guillaume, gives a short history of the progress of the metric system and of the search for the most satisfactory materials for standards, and contributes a memoir on the mercury in glass thermometer The old 'verre dur' used by Tonnelot and Baudin in the 'eighties is no longer made and this has entailed a search for a glass equally good It is now found that a thermometer with a bulb of Jena glass 16 M and a stem of a green glass containing a small percentage of lead is the most satisfactory M Volet shows that the observations of Chappuis on the boiling point of water between 555 mm and 825 mm of mercury require for their accurate representation a trinominal in p M Perard gives an account of the interference methods used for the study and comparison of industrial gauges and similar end standards The volume concludes with an account of the celebration of the jubilee of the foundation of the Bureau, held Oct 5, 1927, when addresses were given by MM Emile Picard, C E Guillaume, and Maurice Bokanowski

THE Annual Report of the United States National Museum, Washington, D C, which corresponds approximately to the British Museum (Natural History), to June 1929, states that at the close of the fiscal year the staff consisted of 47 professional and scientific employees, 42 sub professional employees, 41 clerical, administrative, and fiscal workers, and 181 in the custodial service—311 in all In addition, some 54 other specialists hold honorary appointments in the Museum, many of whom devoted much time to work on the national collections Better conditions of pay have been arranged for the staff, the greater part of the increase of 97,064 dollars in the annual grant having been applied to much needed adjustment in the salary scales, and one gratifying result has been that the personnel has tended to become more stable The number of specimens added to the collections continues to increase, and a survey of the materials in the various departments brings the total number of specimens to 12,029,469, but even this survey is not complete Biology alone contains 8,848,367 specimens In view of this increase, it is not surprising to find that the Director complains of congestion in the present space occupied by the Museum collections, in spite of directive effort to select for preservation only the objects that must be kept and to eliminate material that is not permanently desired

A RECENT addition to the valuable catalogues of the collections of objects in the U S National Museum deals with objects of religious ceremonial It is uniform with the catalogue of objects used in the production of fire and light issued not long ago, and forms *Bulletin* No 148 of the U S Museum The author is the late Dr Immanuel Casanowicz, who died in 1928, after many years' service as assistant curator of the Division of Old World Archæology The catalogue covers the Jewish, Christian, Eastern Church, Mohammedan, Hindu, Buddhist, Parsee, and Shinto religions It is well illustrated by a large number of plates figuring ritual objects and implements, medals, crucifixes, ikons, statues of the Buddha, sacrificial accessories and the like which are in the museum Not merely are the objects of the collections described, but notes on ceremonial and function are added which raise the work from a mere catalogue to the status of a brief introductory manual to the ritualistic side of each religion in turn Such catalogues of classified objects cannot compare with the more comprehensive catalogues of the ethnographical and archæological collections in the British Museum, either in appearance or in the nature of their contents, but at the same time it must be recognised that they are of the greatest value to the student of the various branches of culture, as they bring the material ready to his hand in convenient association

THE two handsome volumes, 1200 pages in all, constituting the annual report of the Director of Veterinary Services, Onderstepoort, Pretoria (Union of South Africa Department of Agriculture Pretoria Government Printer, 1929 10*s* each vol), contain details of a number of important and interesting researches on protozoal, virus, and bacterial diseases of animals, parasitology, pathology, poisonous plants, sterility of cows, and mineral deficiency of the Veld Further outbreaks of botulism among animals and birds are recorded (E M Robinson) A new schistosome, *S mattheei*, from sheep is described (F Veglia and P L le Roux) Skin cancer of the Angora goat in South Africa is dealt with in an exhaustive paper by A D Thomas, who remarks that tumours in the lower animals are not a rarity in South Africa The phosphorus deficiency of the Veld soil and pasture is indirectly the cause of a disease, lamsiekte (parabotulism), of cattle, and is preventible by supplying rations of bonemeal, as described in a previous report (1927) It is now found that the bonemeal has also a remarkable influence in increasing the fertility of the cows in the district as well as causing more regular breeding (P J du Toit and J H R Bisschop) The report is well produced and profusely illustrated with excellent plates, and is worthy of a better binding

SIR WILLIAM BRAGG, director of the Royal Institution and of the Davy Faraday Research Laboratory, has been elected a corresponding member of the Vienna Academy of Sciences

THE third Imperial Entomological Conference was opened in London on June 17 by Lord Buxton The meetings of the Conference are being held in the rooms of the Entomological Society of London, 41 Queen's Gate, S W 7 Among the subjects of discussion are Organisation of entomological departments, entomological work among backward races, tsetse control, control of insects by cultural methods, locusts, biological control of insects, control of weeds by insects, and control of orchard pests In connexion with the Conference, the Imperial Bureau of Entomology has issued a list of entomologists employed in the British Empire, and a summary of data relating to economic entomology in the Empire

A COMMITTEE has been appointed by the Secretary of State for the Colonies, in consultation with the Secretary of State for India and the Forestry Commissioners, to consider and report on the training of candidates and probationers for appointment as forest officers in the government service The members of the Committee are Sir James Irvine, principal of St Andrews University (Chairman), Mr G E S Cubitt late Conservator of Forests, Malaya, Sir Thomas Middleton, Development Commissioner, Mr R L Robinson, vice chairman of the Forestry Commission and Technical Commissioner, Mr F W H Smith, assistant secretary India Office, Mr C G Trevor, late vice principal and professor of forestry, Dehra Dun, India, Major R D Furse private secretary (Appointments) to the Secretary of State for the Colonies Mr G H Creasy (Colonial Office) has been appointed secretary to the Committee

THE Medical Research Council announces that on behalf of the Rockefeller Foundation it has made the following awards of travelling fellowships for the academic year 1930–31 These fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine and surgery, and are likely to profit by a period of work at a chosen centre in America or, in special cases, in Europe, before taking up positions for higher teaching or research in the British Isles Mr R C Brock, Guy's Hospital, London, Dr F B Byrom, London Hospital, Mr D Curran, Hospital for Epilepsy and Paralysis, Maida Vale, London, Dr A A Moncrieff, Hospital for Sick Children, Great Ormond Street, London, Mr A S Paterson, Royal Glasgow Mental Hospital, Dr C C Ungley, Royal Victoria Infirmary, Newcastle on Tyne Dr Moncrieff's fellowship is tenable at Hamburg, the others at centres in the United States Mr Brock and Dr Curran have been appointed on modified conditions while receiving emoluments from other sources

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in education in the Department of Education of the University of Birmingham—The Secretary, University, Birmingham (June 24) A principal of the Northern Polytechnic—The Clerk, Northern Polytechnic, Holloway, N 7 (June 27) A horticultural superintendent under the County Council of the Isle of Ely —The Director of Education, Education Offices, March (June 28) A lecturer in rural science at the East Anglian Institute of Agriculture, Chelmsford —The Clerk of the Essex County Council, Shire Hall, Chelmsford (June 30) A district agricultural organiser and lecturer in dairy husbandry at the East Anglian Institute of Agriculture, Chelmsford—The Clerk of the Essex County Council, Shire Hall, Chelmsford (June 30) An assistant lecturer in mathematics in the University of Leeds The Registrar, The University, Leeds (June 30) An assistant lecturer in physics at the Cardiff Technical College—The Principal, Technical College Cardiff (July 2) A professor of physics in the University College of South Wales and Monmouthshire—The Registrar, University College, Cardiff (July 4) A professor of chemistry and head of the department and a professor of physics and head of the department of the Muslim University, Aligarh, U P, India—Vice Chancellor S R Masood, c/o Box 10, c/o NATURE Office (July 4) A professor of mechanical engineering at the Bengal Engineering College, Sibpur, Bengal—The Secretary to the High Commissioner for India, General Department, India House Aldwych, W C 2 (July 5) A lecturer in mining at the Sunderland Technical College—The Chief Education Officer, 15 John Street, Sunderland (July 5) A lecturer in education in the University of Durham—The Secretary of the Joint Board, University Offices, North Bailey, Durham (July 7) Chief lecturers in, respectively, mechanical engineering electrical engineering and metallurgy, at the Rotherham Technical Institute—The Director of Education, Education Offices, Rotherham (July 8) A demonstrator of physics at Guy's Hospital Medical School The Dean, Guy's Hospital Medical School, London Bridge, S E 1 (July 10) A clinical research worker in mental deficiency under the Medical Research Council, the Governing Body of the Darwin Trust, and the Committee of the Royal Eastern Counties Institution for the Mentally Defective at Colchester—Miss Darwin, The Orchard, Huntingdon Road, Cambridge (July 13) A professor of zoology in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W C 2 (Aug 31) A senior lectureship in education in the University of Liverpool—The Registrar, The University, Liverpool (Sept 30) A lecturer in education at the Brighton Municipal Training College for Women—The Secretary, 54 Old Steine, Brighton A graduate teacher for mathematics and engineering drawing at the Cumberland Technical College, Workington — The Principal, Cumberland Technical College, Workington Masters for, respectively, mathematics, and mathematics and physical science, under the Education Department of Southern Rhodesia, for European Schools — The High Commissioner for Southern Rhodesia, Crown House, Aldwych, W C 2 An aero examiner (metallurgist) under the Aeronautical Inspection Directorate of the Air Ministry —The Secretary (I E 2), Air Ministry, W C 2 An assistant in the department of geography of University College, London—The Secretary, University College, Gower Street W C 1

Research Items.

'Bar-lip' Pottery from Essex and Alderney.—In *Man* for June, Mr. T. D. Kendrick figures and describes two fragments of pottery recently acquired by the British Museum, one from Barkingside, Essex, presented by Mr. Hazzledine Warren and Mr. Ryde, and one from the late-Roman fort known as the "Nunnery," Longy Bay, Alderney, presented by Lieut. C. S. Durtnell. The first was part of a bowl about 20 cm. in diameter which probably had a round base. It was a wide mouthed pot with pinched-in neck and lip slightly everted, but its most remarkable feature was that at its rim there were three large protruding spouts across which the rim of the pot is carried in the form of a deep and thickened bar. The bowl is hand made, clumsily modelled, of a coarse gritty ware and deep smoky brown on both faces. The Alderney specimen has a single spout of much the same size as those on the Essex bowl, but the potting is of a much higher character. In the Museum fur Vaterländischen Alterthumer at Kiel are fragments of at least three bowls of the same type, all coming from Haithabu (Hedeby) at the east end of the Danewirke, a famous mart in Viking days. This gives a date of from ninth to twelfth century for the Kiel specimens, and as the Vikings copied Frankish models, the protype must be sought in Frankish pottery. A jug from Aubres, near Nyons, in the Drôme department of France, shows where the Vikings may have seen something of the sort. The clumsy bowl from Barkingside may be an early attempt, perhaps of the ninth or tenth century, introduced by Vikings from Frisia, while the Alderney fragment may be later, possibly eleventh century introduced to the island by Rollo's men. Dr. Cyril Fox has pointed out to the author that there are similar fragments in the Cambridge Museum for Archæology and Ethnology from Abington Piggots, Cambridgshire.

Totemism in Eastern Australia.—A systematic study of the social organisation of Australian tribes has now been instituted by the Australian National Research Council by means of funds provided by the Rockefeller Foundation. As a result, our knowledge of Australian totemism and related phenomena is being greatly extended. Views hitherto current relating to the system of Arunta totemism as described by Spencer and Gillen are being re-examined. Prof. Radcliffe Brown contributes to vol. 59, pt. 2 of the *Journal of the Royal Anthropological Institute* the results of an investigation among a number of tribes in the northern part of New South Wales in which the special problem was the relation between man and Nature in myth and ritual. It was found that each of the tribes in question performed rites for the increase of natural species. Each tribe is organised into hordes—small exogamous local patrilineal clans. The characteristic feature of the cult among them is that there are several sacred spots belonging to each horde at which increase rites are performed. These spots are marked usually by a water hole, and sacred trees or peculiar stones or rocks. Each is associated with some particular natural species and the rites are simple, usually consisting of stirring up the water-hole, throwing mud at the trees, and so forth. There exists also a system of myths associating the sacred spot with the acts of mythical beings. A cult conforming to this general pattern is widespread in Australia, but with local variations, of which Aranda totemism with its conception of reincarnation is one. It is possible that among the Aranda the association between the increase rite and the horde may be found still to exist. It is concluded that the problem of totemism can only be solved when we have a satisfactorily wide theory of the relation in myth and ritual between man and Nature in the less developed societies both totemic and non-totemic.

Alcoholism.—The May issue of the *Bulletin of Hygiene* contains a review of recent literature on alcoholism by Dr. J. D. Rolleston. Previous contributions to this subject by Dr. Rolleston during the last two years have been noted in Nature of Aug. 25, 1928, p. 285; April 20, 1929, p. 615; Aug. 10, 1929, p. 245. The present review deals with its historical aspects, its prevalence in various countries, with special reference to the cocktail habit and methyl alchol drinking, experimental work, alcohol and aviation, alcohol and economics, the association of alcoholism with other morbid conditions, the decline of alcohol in therapeutics, the diagnosis of alcoholism by colorimetric methods, alcohol and longevity, legislation and treatment. A bibliography of thirty-six references to the literature of nine different countries is given.

Biochemical Aspect of the Recapitulation Theory.—The text of a very interesting paper under this title by Dr. Joseph Needham, in *Biological Reviews*, vol. 5, April 1930, may be said to be the observation that the chick embryo for a short time in its early development excretes 90 per cent. of its nitrogen as ammonia, then for a short time 90 per cent. as urea, and finally 90 per cent. as uric acid. From the recapitulatory point of view this is very suggestive since marine invertebrates excrete their waste nitrogen as ammonia, fishes and amphibia as urea, and sauria and birds mainly as uric acid. Needham brings into line with these observations a number of other biochemical data; for example, the appearance of hormones in the developing embryo, none being present in the unfertilised egg, whilst they are also notoriously deficient in the invertebrates. Needham argues that recapitulation may be regarded as fundamentally the result of the necessary passage from simplicity to complexity, from low to high organisation, which is entailed by the metazoal sexual system of reproduction, with its single egg cell.

Vole Cycles in Great Britain.—In view of the enormous destruction which has occasionally been caused in Great Britain owing to abnormal plagues of voles or short-tailed field mice (*Microtus agrestis* and *hirtus*), the importance of an understanding of their bionomics is of obvious importance. For some time A. D. Middleton has been endeavouring to collect from foresters, farmers, and naturalists, records of the annual fluctuations of this pest, and his investigation shows that there is a well marked periodicity in numbers (*Jour. Ecology*, vol. 18, p. 156). Maximum numbers occur approximately every fourth year, and the graph which illustrates Mr. Middleton's paper shows that unusually large numbers were present in 1922 and 1926. On these facts a vole plague (possibly on a smaller scale) may be looked for in the autumn of the present year, but there is a possibility that the graph may be misleading as regards intensity, since reporters are more likely to retain vivid memories of the more recent events. Steps are being taken, however, to place future records on a more reliable statistical basis. The causes of the cycle are not yet fully understood, but there is evidence that, as in so many other rodent plagues, disease is a controlling factor in some instances, although climatic factors are also involved.

Hair of the Fossil Ground-Sloth (Nototherium).—A reprint received from Leon Augustus Hausman (the source of which unfortunately is not indicated) gives an interesting account of a peculiar feature of the hair of the fossil ground sloth (*Nototherium shastense*) recently set up in the Peabody Museum. Only one sort of hair could be seen, corresponding to the over hair of modern mammals; there was no trace of an undercoat of fine hair. The shafts of the hair showed the typical structures, medulla, cortex, cuticle, and pigment granules, and the cuticular scales could easily be distinguished. Where the scales were present, there occurred on the surface of the shaft minute oval bodies which suggested the algal cells present on the hairs of modern South American sloths. Nothing like them has been seen on the hairs of several hundred mammal species examined, and the author, though he does not commit himself, leans to the opinion that they represent an algal association on the hair shafts. We take this opportunity of directing the attention of readers to an excellent and fully illustrated article by the same author on "recent studies of hair structure relationships" in the *Scientific Monthly* for March.

Control of Greenhouse Red Spider.—A new leaflet (No. 99) has been issued recently by the Ministry of Agriculture on the subject of the greenhouse red spider. This extremely small, but notoriously injurious pest attacks many glasshouse plants, and since it is able to increase with extraordinary rapidity, readily becomes a serious menace to growers. Cucumbers and tomatoes are chiefly affected, the plants becoming hardened and stunted in growth, and the leaves injured. Among crops in the open, hops and strawberries are particularly liable to damage. The attack usually begins in the spring and continues during the summer, when the many successive generations feed and lay their eggs upon the under sides of the leaves. In October the female, after fertilisation, changes from a greenish black to a brilliant red colour. In this condition the mites leave the plants, preparatory to hibernation, become gregarious, and live in a common web. Although they do not feed in the winter, they only become inactive at temperatures far below freezing point. As regards methods of control, fumigation with naphthalene is extensively used for cucumbers, but is not suitable for tomatoes or carnations. Spraying with petroleum emulsions is also an effective measure against attacks on cucumbers or tomatoes, but should not be used for carnations or peaches. For the two latter crops, liver of sulphur is particularly suitable, but for safety spraying must be done in the evening or during dull weather. Other remedial methods are also quoted, and details of the quantities and the conditions under which the various fumigants and sprays are used to best advantage are supplied.

Species and Races in the Salmonidæ.—The work of Dr. H. Henking on salmon, sea trout, and trout is of great interest. In his memoir "Untersuchungen an Salmonidae mit besonderer Berucksichtigung der Art- und Rassenfragen. Teil I." (Conseil Permanent International pour l'Exploration de la Mer. *Rapports et Procès-Verbaux des Réunions*. Volume 61, November 1929) he describes his experiments dealing with racial studies which were undertaken at the instigation of the Limnological Committee of the Council at its meeting in June 1928. In addition to the experimental work a large amount of material has been examined which was collected for many years by Germany, chiefly from the Pomeranian coast, but also from the west coast of Schleswig-Holstein and some samples from the North Sea. As is well known, the salmon and the sea trout pass their life between sea and fresh water, whilst the trout lives almost wholly in fresh water. It is shown in this report that pond trout, if transferred to slightly salt water, such as the Baltic, grow so like the sea trout that it is almost impossible to distinguish them, although there is a tendency at first to return to the fresh water. When established in the Baltic, however, the fish grew to a large size. The conclusions are that the salmon is a distinct species, the trout and sea trout together forming another species, although the two latter usually can be easily distinguished by their size and habits of life. Salmon and sea trout are sometimes difficult to separate, but Dr. A. C. Johansen has shown that there are differences in the gill rakers. Such differences, together with those in the vomer and the os lingue, are here shown to be good distinguishing characters. Hybrids can be produced artificially between salmon and trout, salmon and sea trout or trout and sea trout, but so far no natural hybrids are positively known.

Cocksfoot Grass.—The result of a four years' field trial between indigenous, New Zealand, Danish, and French cocksfoot grass is the subject of an article by Prof. Stapledon in the *Welsh Journal of Agriculture*, vol. 6. New Zealand and indigenous strains are closely allied and differ greatly from the Danish and French types. Although the latter start growth earlier in the spring, and may give the better yield in the first two harvests, the New Zealand and indigenous strains invariably produce the best aftermath and are decidedly the most persistent; further, they are more winter green and their sward is less woody. The leaf to stem ratio in the shoot is higher in the New Zealand and indigenous species than in the Danish and French, and since the heaviest response to manuring, from the point of view of yield, is obtained when the bias is in this direction, it is specially worth while to apply liberal dressings of fertilisers to those leafy strains of the grass. The effect of different cutting and manurial treatment on tiller and root development of cocksfoot is also described in the same volume, both pasture and hay *cum* aftermath systems being considered. As regards yield, the plants cut as hay and aftermath gave the best results, but plants cut to 6 in. at fairly frequent intervals considerably outyielded and also showed greater root development than those cut to ground level. This would point to the necessity of avoiding close and continuous grazing if the productivity of a pasture is to be maintained. Nitrogen applied as nitro chalk in heavy incremental dressings had a more pronounced effect on hay *cum* aftermath than on pasture, but all systems of cutting showed a response to nitrogen. A continued plucking of inflorescences was found to increase tiller and root development. The soundness of the practice of running the mowing machine over pastures (at intervals if necessary) to remove excess of flowering shoots is therefore upheld.

Giant Senecios on Kilimanjaro.—Following the recent British Association visit to South and East Africa, accounts of vegetation from interesting localities continue to appear from the pens of botanists fortunate enough to take part in this tour. In the *Kew Bulletin*, No. 3, 1930, Mr. A. D. Cotton has an interesting account of earlier botanical exploration of Kilimanjaro. This mountain, with its volcanic crater, is likely to be more accessible in future to British visitors who may approach it, as did Mr. A. D. Cotton (and Dr. A. S. Hitchcock of the Smithsonian Institution) from the direction of Amani. The two travellers were able to break their rail journey from Amani to Nairobi at Moshi, the bi-weekly train service per

mitting time for a considerable ascent of the mountain The recently opened Kibo Hotel at Marangu provides a suitable base of operations on the south side of the mountain and the proprietor of the hotel owns two conveniently placed resthouses on the slopes at altitudes of 8500 feet and 11,500 feet respectively In four days the two travellers were able to make a comparatively leisurely ascent, Dr Hitchcock collecting up to 14,000 feet altitude, and the list of plants brought back by Mr Cotton shows that a considerable amount of valuable work could be carried out in this period Mr Cotton's account is illustrated by some excellent photographs, taken by Dr Hitchcock, of the arborescent Senecios on the rocky slopes One of these is described as a new species, *S Cottonii* Hutch and Taylor It was not recognised as new until brought back to Kew, so that its altitudinal limits are not clearly known, but it probably grows at higher altitudes than *S Johnstonii*, which grows on the same mountains and is named after Sir Harry Johnston

Observations by Pilot Balloons —The Swedish Meteorological and Hydrographical Office has collected together as part 10 of *Arsbok* for 1928 a number of meteorological observations taken at high altitudes These include aeroplane observations at the aviation stations of Malmslätt and Ljungbyhed throughout the year, and reading by pilot balloons at Malmo and Göteborg for the great part of the year, and at Stockholm, Östersund, and Abisko for the whole year Most of the observations were made below four thousand metres, but a few were made at several stations above five thousand metres At most stations the observations, which are printed in full, were taken almost every day in the month They include temperature, humidity, pressure, wind and cloud

Superconductors —Measurements made at the Leyden Cryogenic Laboratory during the past ten years have established the fact that the following pure metals become superconducting at the absolute temperatures given—lead 7 2°, mercury 4 2°, white tin 3 8°, indium 3 4°, thallium 2 5°, and gallium 1 1° Measurements have been made more recently by Profs de Haas, van Aubel, and Voogd on the resistivities of alloys of these metals with each other and with other metals not showing superconductivity at temperatures at present attainable Their results are given in Leyden *Communications* 193, 197, and 199 When thallium is alloyed with bismuth or tin with antimony superconductivity occurs at a higher temperature than it does in the pure metal, but when tin is alloyed with silver or copper the alloy is not superconducting On the other hand, an alloy of 4 per cent bismuth in gold becomes superconducting at 1 9° although neither constituent is superconducting In the *Transactions of the Royal Society of Canada* for April, Prof J C McLennan and Messrs Allen and Wilhelm show that by the addition of bismuth to lead or to lead tin alloys the temperature at which superconductivity begins may be raised, for example, to 8 8°, that is 1 6° above that for pure lead

Spectroscopy of the Night Sky —The April number of the *Canadian Journal of Research* contains a paper by Prof J C McLennan and Mr H J C Ireton, describing a special spectrograph for investigation of light from the night sky The instrument has not the usual symmetrical form, the collimator lens being an achromatic cemented doublet of 50 mm aperture and 56 cm focus, and the camera lens either a single aspherical lens designed to give the maximum concentration of light for the mercury green line, or a four component F/1 lens of 50 mm focus, designed to give good focus of the entire spectrum on a flat but tilted plate The instrument is mounted so that the collimator can be readily directed to any part of the sky Some tests which have been made at various stations in Canada and England, using the compound camera lens, have shown that the green line (5577 A) from the non polar aurora can be photographed in as short a time as ten minutes under favorable conditions, so that it will be now easily possible to follow the change in intensity of this radiation throughout the night, as well as to study the radiation coming from different parts of the polar aurora With exposures of between one quarter and one half of an hour, with a slit 1 mm wide, six lines were obtained in the spectrum of the light from the polar aurora, in addition to the green line and the two nitrogen bands at 3914 A and 4278 A

Crystal Structure of Normal Paraffins —Dr A Müller has contributed a paper to the May number of the *Proceedings of the Royal Society* on the crystal structure of the normal paraffins, based on an X ray investigation of a number between C_5H_{12} and $C_{30}H_{62}$ Between liquid air temperature and the melting point, the coefficient of expansion has been found to be different for each of the two axes perpendicular to the carbon chain, and the expansion in the last direction is too small to be measured under the conditions of experiment The higher hydrocarbons have been shown to crystallise in a form which is the same for odd and even members, differences between the behaviour of the two types of molecules first becoming apparent when the carbon content is decreased About $C_{20}H_{42}$, two alternative structures are found for each compound in the even series, whilst in the odd series the transition takes place between $C_{11}H_{24}$ and C_9H_{20} An observation of special interest is that the substances tend to form layer structures in the immediate neighbourhood of the melting point, the two sets of orientations of the cross sections of the molecules appear to give place to a more or less definite single orientation, and it is suggested by Dr Muller that it may prove possible to influence the balance of the internal forces in the crystal in a similar way by an external electric or magnetic field in this region

Photolysis of Aqueous Hydrogen Peroxide —The April number of the *Journal of the Chemical Society* contains two papers on the above subject by Allmand and Style The results were found to be very complicated The velocity of decomposition was found to vary with the square root of the light intensity, an unexpected result which suggests the formation of a catalyst by the action of light The effect of concentration was also unexpected, since the quantum efficiency increased steadily as the solution was diluted, and the thermal velocity also increased over the greater part of the concentration range covered In some cases the quantum efficiency passed through a maximum with constant intensity as the concentration of peroxide increased The value of the quantum efficiency indicated a catalytic chain with a life of about 1 sec The theoretical bearings of these results are discussed, including the observation that the temperature coefficients of photolysis decreased with increasing frequency, which suggests that they are concerned with the primary process only It is suggested that, since only a very small proportion of the absorbing molecules react after absorption, the reaction chains must be very long The square root relation suggests that the catalyst, of mean life of 1 sec , may consist either of OH groups or oxygen atoms, produced in the liquid phase It is pointed out that a complete theoretical interpretation of the results cannot be given at present

Photo-Electric Cells

THE recent discussion on magnetism (see NATURE, June 7, p 874) afforded an example of a symposium on a subject academic and in some respects aloof from the problems of everyday life The discussion on June 4 and 5, organised jointly by the Physical and the Optical Societies is at the opposite pole Although the photo electric effect both raises and resolves many recondite problems in modern physics, its applications may touch modern life at points so far distant as photo therapy and greyhound racing, and it was in great measure on applications that the interest of the discussion centred

That a metal plate, exposed to the light from an arc, acquires a positive potential—indicating therefore the emission of electrons—was observed so long ago as 1888 by Hallwachs and facts of fundamental importance were rapidly accumulated by Elster and Geitel, who demonstrated in particular that while ultra violet light was the effective agent in establishing the positive potential of an ordinary metallic plate, the alkali metals, sodium potassium, and rubidium, were sensitive to rays from the luminous portion of the spectrum

Einstein in 1905, using the hypothesis of light quanta, showed that the maximum kinetic energy of electronic emission was a linear function of the frequency (ν) of the light employed In fact,

$$\tfrac{1}{2}mv^2 = h(\nu - \nu_0),$$

where $h\nu_0$ is the 'electron affinity', and is a measure of the loss of energy suffered by the electron in escaping from the interior of the atom This equation, which is the basis of one of the most accurate methods for the determination of Planck's constant h, suggests that there is a light frequency ν_0 characteristic of the metal on which the light falls, and such that, if the incident light has a frequency less than ν_0, no electron emission takes place

The fact that a metal such as potassium is sensitive to ordinary light at once suggests its use in a cell in which the electronic current so produced may be measured, and its variation studied with variation of the incident light Again the photo electric current may be amplified by valve circuits used outside the cell, or may be magnified within the cell by filling the cell with gas, applying a relatively large electric field and so producing ionisation by collision

Obviously, constructional problems of no small difficulty at once present themselves, and, these problems solved, with the many applications of photo electric cells, the question of standardisation arises It is, for example, a matter of primary importance that the gas filled cells now so largely used in connexion with talking films should be standardised as regards size, voltage, and terminal arrangements This and allied matters are discussed in detail by Dr Norman Campbell, while the problems of manufacture are very fully described in connexion with the thalofide cell (a cell sensitive to the infra red, in which the active substance is oxidised thallium sulphide), barium photo electric cells, sodium, and selenium cells

Theoretical problems did not bulk largely in the discussion Dr Campbell described a theory of selective emission in which it is suggested that in selectively emitting surfaces an electro negative element is universally present Further, following a clue given by the recent work of Fowler and Wilson, the conditions for selective transmission are assumed to be fulfilled if the potential changes at the transmitting surface are such that a 'valley' of potential is formed between two 'peaks' so situated that the waves associated with the electrons are capable of forming stationary waves between the sides of the valley Two investigations of valve amplification of photo electric currents complete the more important theoretical studies read during the discussion

The papers presented may conveniently be grouped under the main headings, history and development, theory, manufacture, and applications Naturally, the application of widest interest is to photometry, and it is not surprising that eleven out of the twenty seven papers presented deal with various aspects of photometry The problem is not easy It has been well remarked of the human eye that "an instrument that will work with almost equal precision in illuminations differing in a ratio of ten thousand to one is not likely to distinguish easily small differences of illumination" Photo electric methods are considerably more precise but it must be carefully considered what that precision measures, in view of the fact that two lights, judged by the eye to be equal, will not be rated as equal by a photo electric cell unless they have the same quality, and further it may be debated whether high precision is worth while, when we remember that in problems of vision the eye is the final standard However that may be, photo electric photometry is coming into wide use, and the papers dealing with precision measurements in photometry, the comparison of lights of very small intensity, the photo electric measurement of daylight and of under sea illumination photo electric photometry in relation to photo therapy, and spectro photometry, form a most helpful contribution to the discussion of this important branch of the subject

In the section dealing with measurements, attention may be directed to a description, by Mr Eric Moss of a very compact null electrostatic method involving the use of the Lindemann electrometer, for the absolute measurement of the photo electric current

A particularly neat application of the photo electric cell to the measurement of small angles was described and demonstrated by Dr Perfect, in which an image of a narrow slit is focused on the razor sharp edge of a steel prism and is thus divided into two components, the relative intensity of which varies with the position of the image of the slit This relative intensity is measured by allowing the components to 'flicker' on a photo electric cell The amplified alternating photo electric current is rectified by a commutator, and its magnitude measures the relative intensity required In the experiment as shown displacements of the beam of light which forms the image of the slit are compensated by means of a hollow prism containing air, the internal pressure of which may be varied It is possible by this arrangement to measure angles of less than 15″ with a probable error of the order of 0 05″

The discussion of the papers provided an occasion for a lively duel concerning the relative merits of the selenium cell and the photo electric cell But a welcome innovation, that of demonstrations, during the tea interval, of the subjects of papers of experimental interest, gave an opportunity, of which most of the members of the audience made full use, for that informal interchange of ideas which is, perhaps, one of the most valuable features of a discussion This apart, the experimental illustrations, which included an exhibit of photo electric cells of the type developed by Prof Lindemann, and a demonstration by Prof Thirring, of Vienna, made all the difference, for one hearer at least, between vague and vivid memories of a very valuable discussion

ALLAN FERGUSON

New Recording Anemometers

WE have received a communication from Prof W W Shoulejkin, of the Institute of Physics and Biophysics of Moscow, giving particulars of apparatus which he has designed for automatic measurement of the two following quantities

(1) The amount of air that passes in a given interval of time across a unit of area normal to the instantaneous flow of the wind This is a modification of the ordinary Robinson anemometer, arranged so that a paper tape is unrolled by an amount dependent upon the flow required

(2) The instantaneous components of unit wind velocity in any two horizontal directions at right angles, or, in other words, the values of cos θ and sin θ, where θ is the angle between the direction of the wind and any fixed horizontal datum line, for example, the tangent to the coast line at a seaside place

No special difficulty appears to have been attached to the designing of suitable link mechanism for achieving these ends, and it is stated that the apparatus is not costly to produce A specimen has been supplied to the hydrophysical station of the above mentioned

FIG 1

institute at Kaziveli (Crimea) for use in solving problems connected with the transference of heat and water vapour from the Black Sea to the adjacent land

Another use suggested is for determination of the mean vector speed and direction of the wind at any place In this case the axis of reference will be the east west or south north line

The mechanism for achieving item (1) above is shown in Fig 1 *R* is a ratchet wheel, and *M* an electromagnet Every time that the cups of the anemometer complete one revolution, they complete an electrical circuit which brings this electromagnet into operation, and the latter turns the ratchet wheel

FIG 2

forwards by one tooth, this causes a definite length of the tape *T* to be unrolled *D* is a disc which bears twelve rubber zeros and twelve rubber dots on its face, equally spaced around the axis The disc *D* is turned by the hour hand of a clock, so that every half-hour a zero or dot comes opposite to the tape The minute hand *S* of the clock completes an electric circuit through screw *A* or screw *B* every time that this happens, and by this means another electromagnet is bought into action which draws forward the iron disc *H* and makes a zero or dot on the tape In this way the run of wind for each half hour can be measured on the tape

The mechanism for achieving item (2) is shown in Fig 2 *T* is the axis of a wind vane to which is rigidly attached an inclined disc *K* The changes in the direction of the wind therefore cause *K* to revolve in a skew manner

A roller attached to a sliding piece *P* conveys the simple harmonic movement in the vertical of the upper surface of the disc *K* near to *P* to a pen arm (*F*) linked with *P*, this movement being recorded on a chart attached to the drum *U*, which is turned by clockwork In a similar manner, a second pen conveys the vertical movements of the disc at a point 90° from *P* through the agency of the sliding piece *L* Now the difference in phase of 90° ensures that if the apparatus is so set that the displacements of *F* are proportional to the cosine between the direction indicated by the vane and the axis of reference (for example, the coast line), then the second pen will record the sine of that angle

Atlantic and Pacific Land-Bridges [1]

THE value of zoogeography as the pathfinder for geology is being more widely recognised Dr von Ihering summarises in this paper some of the conclusions from his life's study of the biological relations of South America to the history of the Atlantic and Pacific Oceans He agrees in general with the conclusions put forward in 1929 by Prof J W Gregory (see NATURE, April 20, 1929, p 622) in the presidential address to the Geological Society on the "History of the Atlantic" Dr von Ihering considers that the North and the South Atlantic were separated until the Miocene period by land that extended from West

Africa to the Antilles and South America South of that land there was some connexion between the seas of Egypt and South Africa The faunas of the North and the South Atlantic first intermingled in the Upper Miocene period

The argument for the separation of South America and Africa by drift based on the shape of South America is invalid, as that shape was developed only in the Middle Quaternary Previously the South Atlantic was a warm sea, and mangroves lived as far south as the Rio Negro earth movements then admitted a cold current, and the mangroves were driven 12° northwards, the change of climate exterminating the great Argentine Edentates

The Pacific Basin in Upper Cretaceous time was traversed by a land for which is suggested the name 'Archipacifis' Its eastern part extended along western North America as Schuchertland and along South America as Burckhardtland The three sections were each a centre of mammalian development The *Notostylops* fauna and the Dakota flora reached Patagonia by way of Archipacifis The first immigration was earlier than the advent of Creodonts

Archigalenis is a remnant of Archipacifis, and was the only Kainozoic trans Pacific land bridge it lasted until the end of the Miocene period To land west of America was due the range of the American Edentates, the intermingling in Patagonia of the northern and southern floras, and the occurrence in Mexico of an outlier of the southern crayfish and their parasites

The view that the bears reached South America by Miocene time cannot be maintained, as it is based on fossils from the Pampas Formation having been accepted as from the Entrerios Beds The isolation of Patagonia from Brazil until the Middle Miocene is now proved by deep bores under the pampas

A land connexion across the southern Pacific between Australia and Patagonia is shown by, among other evidence, that of *Prothylacinus*, which, with its eight incisors, is a carnivorous marsupial, and not a Creodont

[1] Substance of a paper by the late Dr H von Ihering on Land Bridges across the Atlantic and Pacific Oceans during the Kainozoic Era communicated by Prof J W Gregory to the Geological Society of London on June 11

Technical Teachers in Conference

THE twenty first annual conference of the Association of Teachers in Technical Institutions was held at Brighton during Whitsuntide when the retiring president, Mr A E Evans (Battersea Polytechnic) installed Mr H A Norman (Headmaster, Junior Technical School, Bury) as president for the coming year

Delivering his presidential address, Mr Norman commented upon changes in industry and education It is not yet fully realised, he said, that a provision of technical education which suits an industrial system of small manufacturers and operations carried out by large skilled labour forces does not meet the needs of a changing system in which industry is organised in larger units and in which a more highly trained skill is necessary in a smaller body of workers Among the steps which are being taken to meet the problems presented by this change he indicated the work of the Emmott, Malcolm, and Balfour committees which dealt with problems of education and industry, the series of inquiries, memoranda, and reports which are being steadily made by the Board of Education, and the government committees on salesmanship and engineering He specially stressed two reports on local areas, Yorkshire and the West Midlands metal working area

Surveying the activities of the A T T I, the president insisted that they are not concerned alone with problems of industry and technical education A well-balanced system of education needs co ordination of all its branches It is to be expected, therefore, that teachers' associations should form joint committees to examine mutual problems Such joint committees (for example, the Joint Six Committee of the N U T, four secondary associations, and the A T T I) are attempting to frame policies and to make decisions which affect the whole teaching world They are acquiring a status which suggests they will be able to take other steps which may be desirable Recently, it is true, when questions of detail were discussed, the need for independent action by some of the constituent associations had appeared—a fact which points to the conclusion that attempts to force unity will tend to perpetuate differences rather than to promote common action

Mr Norman made a special plea for junior technical schools in connexion with the raising of the school leaving age It is clear, he said, that the change will profoundly affect work which falls within the province of the A T T I Technical institutions will expect, as a result of the advance in staffing and equipment which the raising of the age should involve, that students will enter on technological studies much better prepared than is now the case From the experience of the junior technical school the question of staffing is of vast importance, since the success of any scheme depends ultimately on the teacher The raising of the leaving age will keep within the ranks of full time pupils those who are growing from childhood to adolescence, for all pupils a large proportion of this period of rapid growth and emotional change will, in future, be accomplished during school life What steps are being taken to meet the new facts and conditions? Endless heavy and monotonous toil such as is often suffered by children who enter industry at twelve and thirteen years of age is not part of the birthright of any child, but neither is an education which does not satisfy because it fails to use the ambition of boys and girls to be up and doing in the world There is a part in all of us which is practical rather than wholly bookish, there are children whose whole nature can best be developed by reference to those practical instincts The admitted success of the junior technical school has been due to the fact that, while it does not neglect the academic side, a good proportion of its time is spent in pursuits which involve practical work in rooms other than class rooms Its staff, too, includes teachers who are themselves directly acquainted with the conditions of life which face pupils not only in industry and commerce, but also in the greater part of the circumstances arising therefrom which go to make up the life of a young person

Mr Norman insisted that the A T T I could not wholly discharge its function through the media of its local and national activities The advance of science is slowly breaking down international barriers, certain international problems cannot, therefore, be avoided He was happy, however, to be able to report work done in connexion with the interchange of teachers through the English speaking Union, and the share which the association has taken in the work of a committee of local education authorities, teachers' associations, and the League of Nations Union, which,

with regard to the inclusion of League of Nations teaching in schools, has recently presented its report to the President of the Board of Education

Among the resolutions dealt with by the Conference was one which urged the necessity for connecting links between government departments concerned with education schemes (for example, Ministries of Health, Labour, Agriculture, and Education), and one which pleaded for legislation recognising for purposes of superannuation all full time service in university colleges, prior to the introduction of the present university superannuation scheme, as service in a technical institution

University and Educational Intelligence

LONDON —Applications are invited for the Laura de Saliceto studentship for the advancement of cancer research The studentship will be tenable for not less than two years, and the annual value £150 The latest date for the receipt of applications by the Academic Registrar, University of London, South Kensington, S W 7, is July 1

MANCHESTER —A limited number of research scholarships in technology will be awarded in July next by the Manchester Municipal College of Technology The value of each will not exceed £100 Research may be undertaken in any of the following departments mechanical engineering, electrical engineering, municipal engineering, applied chemistry, textile industries, photographic technology, printing, and industrial administration There are also scholarships of a yearly value of not more than £100 each, to part time students of the College and others who are Manchester ratepayers or sons or daughters of Manchester ratepayers Applications must reach the Registrar on June 27 at latest

OXFORD —In proposing the acceptance of the offer by Sir William Morris to place the Radcliffe Observatory site and buildings in the hands of trustees for the benefit of the Radcliffe Infirmary and the Medical School, Professor G Dreyer directed attention to the unique character of the gift, spoke of the closer connexion between the University and the Infirmary which it would favour, and pointed out that it would provide room for the extension of the Infirmary, and for the development of post graduate teaching

The report just published of the Delegates of the University Museum announces that a scheme has been put into operation whereby details of certain vacancies requiring candidates with scientific training can be brought to the notice of the teaching staffs of the Museum departments

The reports of the various scientific departments contain lists of research work published during the year, and accounts of accessions to the collections These are especially copious in the case of the Pitt Rivers Museum and the department of the Hope professor of zoology Noteworthy among the former are a collection from the Bororó tribe of Brazil, made by Mr George M Dyott during his expedition in search of traces of the late Col Fawcett, and a very remarkable series of wooden objects found in a cave in Tanganyika Territory, among the latter a fine series of Paraguayan butterflies presented by the late Dr Charles Hose, a great collection of ants made by Mr W Cecil Crawley, a large number of Coleoptera from Windsor Forest given by Mr Horace Donisthorpe, and a very full collection of British Lepidoptera by Dr Nevil Sidgwick This collection, part of which was made in the company of the late Mr Arthur Sidgwick, contains a specimen of the North American *Danaida plexippus* caught at Lyme Regis in 1886

A SCHOLARSHIP of the value of £100 for post graduate research on wool has been instituted by the Weavers' Company The research will be carried out in the laboratories of the Wool Industries Research Association Applications should be sent not later than June 30 to the Secretary, Wool Industries Research Association, Torridon, Headingley, Leeds

FROM the Imperial College of Tropical Agriculture, Trinidad, we have received a pamphlet containing a prospectus for 1930–31, the principal's report for 1928–29, and a register of staff and students Courses are offered in agriculture, botany, chemistry and soil science, economics, mycology and bacteriology, tropical sanitation and hygiene, technology (chemical machinery, sugar technology, colloid science, physical chemistry, field and factory control), veterinary science, zoology, and entomology A diploma course covering three years, a one year course, refresher courses, and various post graduate courses are provided Fifty five students were in residence last year, including twenty seven graduates The instructional staff numbered sixteen In addition to numerous shorter notes and articles in the college journal, *Tropical Agriculture* (6d monthly), twenty-one scientific papers were published during the year Research is, in the main, concentrated, so far as concerns long range investigations, on four crops, namely, sugar cane, bananas, cacao, and limes The plant includes a sugar cane factory in which more than a thousand tons of cane were dealt with during the year

Historic Natural Events

June 23, 1783 Severe Frost — Great damage was caused in Britain by a severe frost Trees and fruit crops suffered badly, and also barley, oats, and rye Ice a quarter of an inch thick was formed on tubs of water

June 23, 1783 Dust Haze —Gilbert White, in the "Natural History of Selborne", describes a peculiar haze or smoky fog which prevailed for many weeks in Britain and many parts of Europe on June 23–July 20, "during which period the wind varied to every quarter, without making any alteration in the air The sun, at noon, looked as blank as a clouded moon, and shed a rust coloured ferruginous light on the ground and floors of rooms, but was particularly lurid and blood coloured at rising and setting All the time, the heat was so intense that butchers' meat could hardly be eaten the day after it was killed, and flies swarmed so in the lanes and hedges that they rendered the horses half frantic and riding irksome" The haze was undoubtedly due to volcanic dust from the eruption of Asama

June 23, 1921 Thunderstorm and Flood —The city of T'ung Chuan, in the province of Sz Chuan, in the interior of China, was visited by a severe thunderstorm which began at 1 A M and continued for twelve hours During that time the rainfall amounted to 7 45 in The level ground surrounding the city was flooded knee deep and corn was beaten down everywhere The water entered the west gate, destroying many huts, and even some more solidly built houses fell down Several people were drowned and many others rendered homeless Two soldiers were struck by lightning and killed, others were rendered speechless The Chinese said that they had not experienced such a storm for many years, and that it occurred because a dragon had been stolen from one of the temples outside the west gate

June 24, 1034 Frost —The Anglo-Saxon Chronicle records that "On Midsummer Day there was such a vehement frost, that the corn and other fruits of the

earth were blasted and killed, so that thereupon followed a great dearth in all the country "

June 24, 1897 **Hailstorms** —The morning was very hot in England, and during the afternoon a series of violent thunderstorms developed at many widely separated localities The greatest damage was done by a storm which crossed Middlesex and continued to Colchester in Essex, accompanied by violent winds and heavy hail, the stones being described as ' as big as hens' eggs " The storm played havoc with the Diamond Jubilee decorations, broke thousands of panes of glass, smashed tiles, blew down chimneys and trees, ruined crops, and killed thousands of birds There was great distress among the farmers in Essex, for there had not been a bad hailstorm for some years, and many of them had given up insuring against hail, the Lord Mayor of London opened a relief fund for the benefit of the sufferers

June 25, 1545 **Thunderstorm** —A great tempest occurred in Derbyshire, in which trees were overturned and churches, chapels, and houses unroofed In Lancashire hailstones fell, said to be as big as a man's foot

June 28, 1788 **" The Midsummer Flood "**—Whistlecraft, in " Rural Gleanings ", states that the most remarkable rain ever known in northern Suffolk in June, " came down in awful torrents for some hours, until it caused the greatest inundation ever recorded in these parts It has ever afterwards been called ' The Midsummer Flood ' "

June 28–July 4, 1901 **Heat Wave** —A spell of uniformly high temperature produced more serious effects in New York than had ever been experienced before Even at night the thermometer rarely fell below 80° F, and the air was very humid The asphalt with which the streets were paved softened with the heat, and the wheels of vehicles ploughed deep ruts in the roadways Outdoor work was practically suspended, and even the Stock Exchanges in New York and Boston were closed 150,000 people abandoned New York city, and thousands more slept in the public parks, which were kept open at night for that purpose The hospitals were overcrowded with cases of heat prostration, while several hundred people and more than a thousand horses died from heat stroke

June 28, 1917 **Heavy Rain** —A depression passed along the English Channel, and very heavy rain fell over Somerset At Sexey's School, Bruton, the amount measured was 9 56 in, a large part of which fell between 11 P M on June 28 and 1 A M on June 29 This is the heaviest fall in twenty four hours on record in the British Isles At King's School, Bruton, the amount was 8 48 in It is estimated that during this storm 525,000 million gallons, or 2340 million tons of water fell in England and Wales A great volume of water flowed along the valley of the Brue towards Burnham At Bruton the valley narrows, and the town bridge confines the river still further, and here the water, unable to pass, flooded the low lying parts of the town, doing much damage

June 28, 1928 **Heavy Rain** —Continuous heavy rain fell over the mountains of North Wales during strong south westerly winds, the total reaching 7 77 in at Blaenau Festiniog in Merioneth The rainfall was largely due to the mountains, but an analysis of the weather charts showed that the winds were derived from two separate sources, a relatively cool current from the northern North Atlantic and a warmer current from farther south These two currents were brought side by side, and it is probable that the cool current spread sideways under the warmer and moister air, raising it steadily and continuously throughout the day, and so greatly increasing the rainfall

Societies and Academies

LONDON

Linnean Society, May 15 —H R Hewer Studies in colour changes in fish (Pt 5) The colour patterns in certain flat fish, and their relation to the environment Microscopical examination of the chromatophores, which form the basis of the colour patterns, shows that the spots occurring on the upper side of the body may be divided up into groups according to their characters, such as distribution, size, and constituent chromatophores These groups constitute the ' patterns ', and they act as distinct entities, all the spots belonging to any particular pattern reacting in the same manner to any one stimulus The constitution of any given type of spot is remarkably constant with a species Among the fish examined, those having the greatest number and complexity of colour patterns and therefore possessing the machinery for the largest range of adaptation, are the turbot (*Rhombus maximus*) and the brill (*R lævis*) which are noted for their habit of moving over considerable areas A study of the constitution of the spots in young forms in closely related species has demonstrated a series of stages of complexity approximating to the lines along which evolution has probably taken place —E M Delf The release of oogonia in the Fucaceæ The first species considered was of *Bifurcaria brassiciforme*, one of the Fucaceæ common on the shores of the Cape Peninsula Comparison was then made with other genera of intertidal habitats such as *Fucus*, which is habitually exposed during the fall of the tide and *Sargassum* and *Cystophyllum*, which are intertidal but constantly covered even at low spring tides in most localities

Geological Society, May 28 —H H Swinnerton The post Glacial deposits of the Lincolnshire coast The clays which underlie the Lincolnshire marsh land crop out between the tide lines along the coast, and many temporary exposures have been examined in the vicinity of Chapel St Leonards and Ingoldmells These deposits lie upon an uneven floor of boulder clay, and may be divided into Lower, Middle, and Upper Series, separated by well defined erosion surfaces The lower series consists of peat enclosing remains of oak, alder, and birch It was formed during Neolithic times, when the area must have been at least 20 feet above its present level The middle series consists almost entirely of purple and grey buttery clays, and rests upon an eroded surface of boulder clay and peat It is usually 7 feet thick, and is divisible into lower and upper portions by a marked difference in the contained flora The upper series consists of grey, purple, and black sloppy clays, with numerous *Scrobicularia* and *Cardium* in their lowest portions The thickness varies from 18 to 9 feet There is evidence that this series was formed after the Roman occupation The character and contents of these post Glacial deposits indicate deposition under estuarine conditions, associated with the presence of an off shore barrier, probably breached during the thirteenth and fourteenth centuries, thus establishing the present exposed condition of the coast

Mineralogical Society, June 3 —L J Spencer A new meteoric iron from Piedade do Bagre, Minas Geraes, Brazil This mass, found in 1922 and weighing 130 lb, is of special interest in showing on one corner a well marked octahedral fracture, and on a polished and etched section taken from this portion of the mass a complex system of very distinct Neumann lines Neumann lines are twin-lamellæ

produced by gliding on planes of the icositetrahedron (211), and it is believed that these, as well as the octahedral fracture, were developed by the shock of impact when the meteorite fell with its corner on hard rock —**Miss Jessie M Sweet** Notes on British barytes It is shown that the localities of barytes and fluorite follow the outcrop of the Whin Sill in the north of England and of the toadstones in Derbyshire Attention is directed to a change in colour from yellow to blue in some barytes crystals from Mowbray mine, Frizington, Cumberland, on exposure to the light Zoned crystals and some rare crystal forms are described —**M H Hey** On face and zone symbols referred to hexagonal axes The three hexagonal zone symbols for any one zone referred to the Bravais axial system and obtained by cross multiplication of face symbols dropping the first, second, or third index, all obey the Weiss zone law and, when added together, applying a factor of 2/3 for the fourth index, yield a four index zone symbol identical with that obtained for the zone from the gnomonic or linear projection This four index zone symbol also obeys the Weiss zone law if a factor of 3/2 be applied to the unique index when operating upon the face symbols of a face in the zone General expressions are obtained for passing from any one of the three index zone symbols to the other two and also to the four index symbol and vice versa —**L J Spencer** Biographical notices of mineralogists recently deceased (fourth series) For the past three years thirty eight biographies are included Ages range from thirty two to ninety one years, with an average of sixty eight years Prominent are P Groth and G Tschermak, who both died in 1927 —**F Walker** A tholeitic phase of the quartz dolerite magma of central Scotland The tholeites of Dalmeny and Kinkell are described and shown to contain chlorophæite It is demonstrated by means of analyses and refractive index determinations that the residual glass is of acid composition in both rocks a conclusion which does not support some of the ideas of Dr C N Fenner on the crystallisation of basalt —**M H Hey** On pink epsomites and fauserite A supposed specimen of the latter in the British Museum proves to be pink epsomite Fauserite is a doubtful species

Physical Society, June 13 —**E J Williams** (1) The induction of electromotive forces in a moving liquid by a magnetic field, and their application to the investigation of the flow of liquids A magnetic field induces electromotive forces in a moving liquid and by investigation of the e m f 's produced by a known magnetic field it is possible to obtain information about the distribution of velocities in the liquid Potential differences of the order of 10^{-4}-10^{-3} volts, set up by a magnetic field in an aqueous solution of copper sulphate, can be satisfactorily measured (2) The motion of a liquid in an enclosed space The increase of resistance of a column of mercury in a magnetic field, found in experiments on this effect, is due to the internal motion of the liquid produced by the action of the ampère forces between the magnetic field and the electric current traversing the mercury E m f 's so small as 10^{-6} to 10^{-7} volts, induced by a magnetic field in moving mercury, can be accurately measured —**E V Appleton** Some notes on wireless methods of investigating the electrical structure of the upper atmosphere (2) The relations between the optical and equivalent paths of waves deviated by the upper atmosphere and between the rates at which these quantities may vary with time are investigated theoretically, and, from the results of experiments carried out to test these relations, deductions are made concerning (*a*) the existence of more than one ionised region in the upper atmosphere, (*b*) the possible influence of magnetic storms on atmospheric ionisation, (*c*) the gradient of ionisation in the upper atmosphere and its alteration under solar influence at sunrise, and (*d*) the actual height reached by waves deviated in the upper atmosphere —**C R Darling** A simple method of showing the modes of vibration of a wire The wire is heated with alternating electric current and its tension varied, the various modes are easily observable owing to the luminosity of the wire

DUBLIN

Royal Irish Academy, May 26 —**R W Ditchburn** Notes on resolving power The nature of the Rayleigh conception of resolving power and its range of application are discussed We may usefully distinguish three stages in resolution, first, when inhomogeneity may be detected, second when the number and wave length separation of the components can be distinguished, and third, complete resolution when both wave lengths and intensities can be accurately measured The Rayleigh criterion corresponds roughly with the second stage The paper includes sections dealing with (*a*) the difference between visual and photographic photometric resolution, (*b*) the difference between resolution of emission and absorption lines, (*c*) the resolution of lines of unequal intensity, (*d*) the resolution of lines of finite breadth The fundamental conditions affecting the practical efficiency of methods for wave length resolution are considered

EDINBURGH

Royal Society, May 26 —**Niels Bohr** Philosophical aspects of atomic theory Recent experimental and theoretical studies of physical phenomena have revealed a limitation in our ordinary concepts of natural philosophy as regards the description of the behaviour of single atoms This limitation is an immediate consequence of the discovery of the elementary quantum of action, which excludes a simple distinction between the atomic phenomena and the observation, since any observation necessarily involves a finite change in the course of the phenomena This circumstance prevents a pictorial description of atomic phenomena and allows us to apply physical concepts only in connexion with probability considerations The new situation in physics with which we are thus confronted presents a remarkable analogy with situations with which we are familiar from studies in biology and psychology

PARIS

Academy of Sciences, May 5 —**E Goursat** The singular multiplicities of systems in involution —**Georges Perrier** The Rohan Chabot expedition (Angola, Zambezi) This was an expedition organised privately by Comte Jacques de Rohan Chabot A résumé is given of the geographical, magnetic, and meteorological observations —**Ch Achard** and **M Enachesco** The variations, spontaneous or provoked, of the distribution of chlorine between the serum and the blood corpuscles in disease The results obtained broadly confirm those previously described concerning the variations of the chlorine and of the acid base equilibrium in morbid states, particularly in cyclic diseases —**Paul Delens** The analytical representations of cycles of space —**F Campus** Correction of the mean fibre of the arches of barrages —**B Galerkin** Contribution to the general solution of the problem of the theory of elasticity in the case of three dimensions —**Benjamin Jekhowsky** The calculation of the dimensions of the orbit of the new trans Neptunian celestial body —**M** and **Mme Henri Mineur** The

rotation of the local star cluster and the galaxy —**Jean Peltier** The search for defects in ferromagnetic test pieces By the use of a four valve amplifier and a loud speaker, superficial faults of one cubic millimetre produce sounds audible all over the laboratory at present the method is limited by the fact that the penetration is only some millimetres into the test specimen, but this defect may be overcome by the use of more powerful magnetic fields —**E Rinck** The equilibrium, in the fused state, between sodium, potassium, and their fluorides The law of mass action (Na)(KF)/(K)(NaF)=c has been verified, c being a constant of about 0 29 —**Mlle Amagat** The action of sodium amide on some alkyl bromides Bromides of the type $(C_6H_5)R$ CH CH_2Br treated with sodium amide in xylene solution give almost exclusively the symmetrical hydrocarbons C_6H_5 CH – CH R —**Ch Courtot and J Pierron** Contribution to the study of alcohols unsaturated in the β *or* γ positions —**Henri Besairie** The stratigraphy of the secondary and tertiary formations of the province of Betioky (south west Madagascar) —**Jacques de Lapparent** The mineralogical and chemical behaviour of the alteration products of the gneiss of the French central massif, before the establishment of the sedimentary deposits of the Oligocene - **C and M Schlumberger** The electromagnetic determination of the direction of sedimentary deposits —**Mlle Lucienne George** *Ephedra nebrodensis* of the north of Africa An account of the modifications of the plant due to the change in medium, more especially the intense insolation —**A Guillaume** The migration of the alkaloids in the course of the germination of seeds and the formation of the embryos researches on *Lupinus mutabilis*, var *Cruiskanks* —**Antonin Nemec** A rapid method for the determination of the effect of phosphatic manures on the yield of cultures The method is based on the fact that the proportion of ferric oxide in a soil affects the action of a phosphatic manure —**Gordon H Scott** The localisation of the mineral constituents in the cellular nuclei of acini and the excretory ducts of the salivary glands —**A Policard and Mlle V Mouriquand** The tissue reactions provoked by the intraconjunctival injection of particles of asbestos An experimental study of pulmonary asbestosis —**J Abelous and R Argaud** The secretory activity of the nuclei in the suprarenal adenomes —**Mlle Andrée Courtois** The proportions and variations of the phosphorus in the course of nymphosis of some Lepidoptera —**Edouard Chatton, André Lwoff, and Mme Marguerite Lwoff** The Phoretophrya ciliated Fœttingeriideæ, hyperparasites of the Gymnodinioides, parasite Fœttingeriideæ of the Crustacea

PRAGUE

LONDON CLINICAL SOCIETY (at London Temperance Hospital).—Sir Robert Armstrong-Jones The Evolution of the Human Mind (Macalister Lecture).

WEDNESDAY, JUNE 25

GEOLOGICAL SOCIETY OF LONDON, at 5 30.—J E Richey The Geology of the Tertiary Igneous Complex of Ardnamurchan.

ROYAL SOCIETY OF ARTS —Annual General Meeting.

THURSDAY, JUNE 26.

ROYAL SOCIETY, at 4 30 —Prof A V Hill and P S Kupalov The Vapour Pressure of Muscle —Prof A V Hill The State of Water in Muscle and Blood and the Osmotic Behaviour of Muscle —W Sucksmith The Gyromagnetic Effect for Paramagnetic Substances —And other Papers

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —M C Johnson The Effect of Photo-sensitised Mercury Vapour on the Walls of Silica Vacuum Tubes.—H R Nettleton and F H Llewellyn A Sensitive Rotating Coil Magnetometer —L Hartshorn The Frequency errors of Rectifier Instruments of the Copper oxide Type for A C Measurements —D S. Perfect A Method of Eliminating the Effects of Magnetic Disturbances in Highly Sensitive Galvanometers —*Papers to be read in title only* —M C Marsh The Thermal Insulating Properties of Fabrics —W Band The Classical Quantum Theory and X ray Excitation by Canal Rays and Alpha Particles.—A. T McKay Diffusion from an Infinite Plane Sheet Subject to a Surface Condition, with a Method of Application to Experimental Data —S Tolansky . Intensity Modifications in the Spectrum of Mercury

MEDICO-LEGAL SOCIETY (Annual General Meeting) (at 11 Chandos Street, W 1), at 8 —Prof J S Haldane Carbon Monoxide Poisoning

INSTITUTION OF MINING AND METALLURGY (at Geological Society).—Annual General Meeting

FRIDAY, JUNE 27

ROYAL SOCIETY OF MEDICINE (Otology Section) (at Nottingham) —Papers by Dr M Evans, Prof G Guida, Dr Densham, and L Yates

SATURDAY, JUNE 28

ROYAL SOCIETY OF MEDICINE (Orthopædics Section) (at St Vincent s Orthopædic Hospital, Eastcote near Pinner), at 3

ROYAL SOCIETY OF MEDICINE (Otology Section) (at Nottingham)

CONGRESSES.

JUNE 21 TO 28.

ROYAL SANITARY INSTITUTE (at Margate)

Monday, June 23 at 3 —Lord Cornwallis Inaugural Address

Tuesday June 24, at 10 A M —Meetings of Sections and Conferences.

A —Preventive Medicine
I —Representatives of Sanitary Authorities
V —Engineers and Surveyors
VI —Sanitary Inspectors
VII —Health Visitors (including Personal and Domestic Hygiene)

At 8 P M.—Dr O C Bradley Diseases of Domestic Animals from the Human Angle (Lecture).

Wednesday, June 25, at 10 A.M —Meetings of Sections and Conferences

A —Preventive Medicine
B —Engineering and Architecture
D —Hygiene of Food
VI —Sanitary Inspectors
VII —Health Visitors (including Personal and Domestic Hygiene)

Thursday June 26, at 10 A M —Meetings of Sections and Conferences

B —Engineering and Architecture
C —Maternity and Child Welfare (including School Hygiene).
F —Veterinary Hygiene
IV —Medical Officers of Health

Friday, June 27, at 10 A M —Meetings of Sections and Conferences

C —Maternity and Child Welfare (including School Hygiene)
E —Hygiene in Industry
F —Veterinary Hygiene
II —Representatives of Port Sanitary Authorities
III —National Health Insurance Services

JUNE 22 TO 28

INTERNATIONAL CONGRESS OF MINING, METALLURGY, AND APPLIED GEOLOGY (at Liége) —In three sections (*A*) Mining including Reconnaissance and Preliminary Work, Modern Methods of Working Coal Mines, Metalliferous Deposits and Quarries, Generation and Utilisation of Energy, Extraction Ventilation (Gas and Dust), and Mechanical Treatment of Ores and Coal (*B*) Metallurgy, dealing with Blast-furnace Practice, Steel and Ferrous Alloys Foundry Work, Non-ferrous Alloys and Fuels (*C*) Applied Geology, covering Metals, Fuels, Hydrology, and Geophysical Prospecting

JUNE 23 TO 27

MUSEUMS ASSOCIATION (at Cardiff).

Tuesday, June 24 (at Park Hotel), at 10 A M —Sir Henry A. Miers Presidential Address.

At 11 30 A.M —Dr O Lehmann Address
At 3 30 —Dr C Fox The National Museum of Wales

Wednesday June 25 (at Engineers Institute), at 9 30 A.M —Dr C Fox The Affiliation of Museums—the Opportunities and Difficulties of the Parent Museum

At 10 30 A.M —W C Sprunt and Dr T W Woodhead Papers on Rural Science
At 2 30 —Dr F J North Geology in Relation to the Small Museum.
At 3 15 —H A Hyde Botany in Relation to the Small Museum

SUMMER MEETING.

Biology for Young Children

IT is sound educational practice for teachers to avail themselves of the innate interests and inclinations of their pupils, especially in the earliest stages of their training The millennium is not yet, but a little child may lead us towards its advent in the teaching of biology In a paper entitled "The Biological Interests of Young Children", recently published in *The Forum of Education* (vol 7, No 3, and vol 8, No 1), Mrs Isaacs deplores the failure to link up the keenness evinced by little children in animal pets and in growing plants with later biological interests, and gives an illuminating record of her experiences at the Malting House School, Cambridge, with a group of children all of whom were less than seven years of age

Mrs Isaacs maintains that an active, continuous, and cumulative interest in animal and plant life, but particularly in animal life, develops easily and uninterruptedly out of the young child's innate curiosity and pleasure in these things, provided (1) that their adult associates emancipate themselves from prejudice and inadequate thinking as to the order in which plant and animal life should be dealt with, and the range of facts acceptable to children of tender age, and valuable educationally, and (2) that the child's actual direction of interest be followed, and heuristic help given Her records suggest strongly that children at this age are more actively and spontaneously interested in animals than in plants, that the animal interest is far more genuinely biological, plants being to the children little more than suitable gifts and decorations, that the facts of the life cycle in animals are more easily and directly observed and understood by the child, and thus that the animal interest is more easily sustained and naturally linked on to formal biological study

To generalise from comparatively few examples is, perhaps, rash, but Mrs Isaacs' experience will be confirmed by many who have to do with young children, and her conclusions merit careful consideration by those responsible for the education both of little and of older children

Another consideration that emerges from Mrs Isaacs' paper may be termed a moral one There is in most children a curious mixture of tenderness and cruelty towards animals, nor do the behaviour of carnivorous animals, and the apparent inconsistencies of the adult population with regard to animal food, animal clothing, sport and the like, help to make clear to the child that cruelty is wrong,

and that respect is due to all forms of life It was found, however, at the Malting House School that 'looking inside' some dead animals, and hearing something of the functions of the organs exposed by dissection, so far from increasing the impulses to cruelty in children, had the reverse effect The impulse to master and destroy was taken up into the aim of understanding a living mechanism not greatly differing from that of a human being

By encouraging in the children any interest shown in the processes of life, a steadily humane outlook was achieved, and a sense of responsibility towards pets and towards animals in general awakened and enlivened The standard of positive morality engendered by this method is of far more worth than the mere negative of not being unkind, and it expresses itself in eager interest in life histories, and sympathy with all animal activities

---

Egyptian Mathematics

The Rhind Mathematical Papyrus British Museum 10057 and 10058 Photographic Facsimile, Hieroglyphic Transcription, Transliteration, Literal Translation, Free Translation, Mathematical Commentary, and Bibliography In 2 volumes Vol 1 *Free Translation and Commentary*, by Arnold Buffum Chace, with the assistance of Prof Henry Parker Manning, *Bibliography of Egyptian Mathematics*, by Prof Raymond Clare Archibald Pp vii + 210 Vol 2 *Photographs, Transcription, Transliteration, Literal Translation*, by Arnold Buffum Chace, Ludlow Bull, and Prof Henry Parker Manning, *Bibliography of Egyptian and Babylonian Mathematics (Supplement)*, by Prof Raymond Clare Archibald, *The Mathematical Leather Roll in the British Museum*, by Stephen Randolph Kingdon Glanville Pp xvi + 31 photographs + 109 plates + 12 + 8 (Oberlin, Ohio American Mathematical Association, 1927–1929)

When Prof T Eric Peet's handsome and in every respect admirable edition of the Rhind Papyrus appeared in 1923, anyone who read it must have felt that we had at long last (nearly fifty years had passed since the publication of Eisenlohr's edition) a definitive translation and commentary, with all such detailed discussion of points arising on the text and its interpretation as would give Egyptologists and mathematicians, once for all, a sound basis for further researches on the subject The immediate effect of Prof Peet's publication was to usher in an epoch of fresh intensive study of the principles of Egyptian mathematics, which bids fair to put into the shade the work of those pioneers, like Moritz Cantor and Hultsch, who first took the matter up after Eisenlohr First Mr Battiscombe Gunn published in the *Journal of Egyptian Archæology* for 1926 an invaluable critical notice of Peet's work covering fifteen pages of small print, in which he put forward many suggestions for improvements in the translation of the text and the mathematical interpretation, so important were these that, wherever Peet's work is quoted by later writers, we almost invariably find Mr Gunn also cited, the two are associated in a joint article in the *Journal of Egyptian Archæology* of November 1929 on four problems from the Moscow Papyrus, the publication of which in full is expected at an early date But there has been equal activity abroad Important papers have appeared in the last few years, notably those of O Neugebauer (1926), O Gillain (1927), and, last of all, Kurt Vogel in "Die Grundlagen der agyptischen Arithmetik" (1929), a book of 208 pages, which deals mainly with the table at the beginning of the Rhind, showing the decomposition, into a sum of submultiples, that is, fractions with numerator unity, of the results of dividing 2 by each of the odd numbers 3, 5, 7 up to 101, and which seems to be the most comprehensive work of all, since, in addition to the author's own elaboration of his subject, it contains notices of all earlier important contributions to the same

As regards the text and translation of the Rhind Papyrus, one would, on general principles, have expected Peet's edition to remain without a rival for, say, another fifty years Yet, within seven years of its publication, we have before us another which surpasses it in scale and magnificence Peet's edition contained, besides the valuable and comprehensive introduction extending to 32 of the folio pages, and the translation and commentary combined (covering nearly 100 pages), a hieroglyphic transcription of the text on 23 plates, with another reproducing the hieratic text of the New York fragments In the present edition, Vol 1 contains (1) a full introduction on Egyptian arithmetic and geometry generally, on Egyptian measures, and on the methods and aims of the Egyptian mathematician, with notes on the Egyptian calendar and chronology, then (2) a free translation and commentary suitable for the mathematician and the general reader, and (3) the first part (covering the period from 1706 to 1927)

of an extraordinarily valuable bibliography prepared by Prof R C Archibald, of Brown University The bibliography is not confined to works wholly devoted to the Papyrus, but includes numerous references to other mathematical, scientific, and Egyptological works, as well as popular papers and books, besides some of the literature of ancient Babylonian mathematics The bibliography is enriched, in the case of the most important works mentioned, by very useful accounts of the contents of those works, their relation to one another, etc , it covers altogether (with indices) 80 of the large pages , and it is continued in Vol 2 by a supplement of 13 still larger pages dealing similarly with additional works issued down to 1930

Volume 2 contains (1) a photographic reproduction of the whole of the Rhind Papyrus, including the New York fragments, on a scale of five sixths of the original size (31 photographs) , (2), on the right hand pages following the photographs, a beautiful facsimile of the hieratic text (109 plates), in which are printed in red those portions of the text which are written in red ink in the original (Peet had in his edition distinguished the red ink portions by underlining or otherwise) , (3) a hieroglyphic transcription (based on that of Peet) which is annexed to the corresponding hieratic text on each plate , (3), on the left hand pages opposite the facsimile plates, a transliteration of the text with a literal English translation interlined with it In (2), (3), (4) the red ink portions of the original text are printed in red as in (1) Accordingly, as the editors point out, from the free translation of the first volume to the original hieratic writing four steps are provided, and the portions of the original text which were written in red appear in red in each of these steps In addition, the left hand pages contain many notes (some of considerable length) on philological questions, the mistakes of the scribe, and so on One wonders with what feelings the worthy scribe Ahmes, Ahmōse or A'h mosè, who presumably never dreamt of immortality, would regard this superb setting given to his work after 3500–3600 years !

The volumes, planned on this magnificent scale, owe their appearance to the initiative of Dr Arnold Buffum Chace, who, while asking the Mathematical Association of America to undertake the publication, " generously provided the means necessary to ensure its appearance in a form commensurate with its importance ". As compared with Prof Peet, the editors had of course the advantage of being able to use the valuable work done by Mr Gunn and others as regards the text, and by other writers upon the content and the mathematical interpretation

The effect of the new editions and the extensive literature to which they have given rise is distinctly to put a higher value upon Egyptian mathematics than scholars were formerly inclined to assign to it At one time the Rhind Papyrus was classed by one school of thought as the notebook of a pupil, and not a very intelligent one at that, in view of the numerous mistakes which disfigure it But the more it was studied, the more clear it became that there was distinct method in it, as well as a high degree of skill in calculation No doubt the problems dealt with may seem to be mostly practical rather than theoretical Yet there is more science in the treatise than appears at first sight Take first the table of decompositions of fractions which we should write as $2/n$, where n is odd, into a sum of fractions with numerator unity (together with 2/3) for example, $\frac{2}{13} = \frac{1}{8}\ \frac{1}{52}\ \frac{1}{104}$, and $\frac{2}{53} = \frac{1}{30}\ \frac{1}{318}\ \frac{1}{795}$ This table, together with the numerous cases of manipulation of fractions in the rest of the treatise, raises the whole question whether the Egyptian had any general conception of such a fraction as m/n where m is any integer less than n , and it is now clear that he had, although he had no means of writing down such a fraction, and had therefore regularly to transmute it into a sum of unit fractions (with 2/3 in addition) before he could put it on paper The Egyptian regularly used, for adding together a number of his unit fractions, a process equivalent to that of reducing to a common denominator, although he uses no such term , in fact, he was able to manipulate fractions to any desired extent

The importance of prefixing to the treatise the table of decompositions of fractions of the form $2/(2n+1)$ will be readily appreciated In Egyptian arithmetic direct multiplication was limited to multiplication by 2 (rarely 10) at a time Hence the calculator would continually have to write down the result of multiplying a unit-fraction by 2 If the denominator was an even number this meant halving the denominator, simply , but if it was odd, reference had to be made to the table , the reckoner would have, say, to multiply $\frac{1}{23}$ by 2 and he would refer to the table and write down $\frac{1}{12}\ \frac{1}{276}$

Again, if we consider the grouping of the problems into classes such as (1) divisions of loaves, (2) *hau*-calculations, (3) calculations of areas (of triangles, rectangles, squares, trapezia, circles) and volumes of containers (parallelepipedal and

cylindrical), and the occurrence of questions about quantities or numbers in the abstract (for example, "two thirds added and one-third [of the sum] taken away 10 remains [find the number]"), cases of arithmetical progression and one case of geometrical progression, we cannot resist the conclusion that Egyptian mathematics had a theoretical as well as a practical side Though no theorems or rules are stated in general terms (only once does the Egyptian say, "Do the same thing in any example like this"), they can be inferred from the definiteness of the procedure followed in the particular cases

No account of Egyptian mathematics is complete without mention of the Moscow Papyrus about to be published, which contains an application of the correct formula for the volume of a frustum of a pyramid on a square base, namely, $\frac{1}{3}h(a^2+ab+b^2)$, where h is the height and a, b are the sides of the square base and the face opposite to it respectively The difficult question of how the Egyptian arrived at such a formula has already been the subject of discussion in published papers (for example, that of Peet and Gunn in November 1929), and will no doubt evoke many more suggestions as time goes on

It is agreed that the Greeks were the first to conceive the idea of making arithmetic and geometry into sciences logically developed from a minimum number of admitted though indemonstrable principles A suggestion has been somewhere made that, finding in ancient Egyptian and Babylonian documents many ready made solutions of comparatively difficult problems without a hint of any underlying theory or rules, the Greeks *had* to seek for such in order to understand the solutions, and were therefore forced to try to lay down a scientific basis The suggestion is interesting, though, even if it were true, it would not in any way detract from the Greek achievement

Chemical Engineering Economics

Einfuhrung in die theoretische Wirtschaftschemie Von Dr Rudolf Koetschau Pp xii + 155 (Dresden und Leipzig Theodor Steinkopff, 1929) 12 gold marks

CHEMICAL industry is based upon a synthesis of chemistry, engineering, and economics In the early days of chemical industry, each of these components was essentially empirical, both in outlook and method The formulation of the law of mass action and the phase rule marked the development of chemistry into a quantitative science With the help of these great principles, it became possible to define precisely the conditions which determine the successful issue of a given chemical reaction The art of chemistry became an exact science Engineering and economics also, each in its own field, gradually became more scientific

The development of a set of physical and chemical reactions into a successful and profitable industrial undertaking is beset with numerous difficulties which are not at first apparent to the chemist, the engineer, or the economist It is not until the undertaking is attempted that each realises how limited is the contribution that he can make to the common stock The process must operate efficiently, this calls for a knowledge of chemical engineering It must also operate profitably this depends upon the successful application of the principles of economics

When a successful laboratory investigation is being developed into a large scale industrial process, new and often formidable problems arise at almost every stage The minor difficulties connected with the storage and handling of large quantities of widely diverse materials can frequently be overcome successfully by the engineer with some assistance from the chemist The major difficulties are generally associated with the reaction itself Instead of controlling the reaction conditions for a kilogram of material in, say, a glass container in a well-equipped laboratory, it now becomes necessary to control with equal accuracy at every point the reaction conditions throughout a few tons of material It may be necessary to guard against slight local changes in temperature and pressure or in the composition of the materials Traces of impurities derived from some raw material or from the material of which the reaction vessel is made may vitiate the process or spoil the product It is also necessary that as much of the product as possible must possess the right degree of chemical purity and must be in the most suitable physical condition

These requirements provide problems in the design and operation of chemical plant which frequently are unfamiliar both to the chemist and the engineer The scrap heaps of our older chemical works bear witness to the empirical methods by which the chemist and engineer formerly strove together to design the most suitable form of plant The chemist and the engineer now know that mere co-operation is not enough The problems of chemical engineering must be investigated scientifically by

men who, having been trained in the principles of chemical engineering, are able to understand the precise way in which the principles of both chemistry and engineering are modified and extended by their common fusion in the melting pot of chemical industry

The process, although efficient from the purely chemical engineering point of view, has yet to be made profitable The operating conditions prescribed by the chemist and modified to meet the engineering requirements of the process must now be further modified in accordance with economic requirements The site and size of the plant, the selection of raw materials, the working efficiency and the percentage yield, the degree of purity of the product and its physical condition, the relative importance of plant costs and labour charges, all these and many other factors depend upon economic considerations When the final adjustment of the working conditions has been made and all three sets of conditions have been fused together, the final result, depending as it does upon all of them but differing essentially from each, may be stated in terms of chemical engineering economics

The formulation of the underlying theory of this complex subject is the purpose of this little book, which we have read with great interest The author, with great industry and considerable ingenuity, has attempted to co ordinate the underlying theories of chemistry, engineering, and economics in so far as they are related in chemical industry, with the object of providing a foundation upon which a rational theory and method of chemical engineering economics may be developed An attempt is made to provide a suitable notation by means of which the different sets of factors may be expressed individually Their influence upon one another and the resulting effect of their combined operation in any particular process may then be represented mathematically The book abounds in quotations from the writings of German industrialists and scientific workers, and is interesting in so far as it reflects the present trend of industrial thought in Germany It is a notable book, of interest both to the chemical engineer and the economist It provides the basis of a method by which the designs and estimates of the chemical engineer may be related to economic requirements The economist will find in it much that will help him to relate his science to the underlying chemical and chemical engineering factors which play an essential part in all industrial chemical enterprise

Trade Rivalry and World Peace.

America Conquers Britain a Record of Economic War By Ludwell Denny Pp xi + 429 + xvi (London and New York Alfred A Knopf, 1930) 12s 6d

MR LUDWELL DENNY'S book is the most complete, well documented, and interesting account of American and British rivalry in trade and finance that has yet appeared It deserves close study, especially by all believers in growing international friendship, because, although the facts it describes are all capable of pacific settlement, they contain much dangerous explosive material and have in the past been treated far too carelessly They are also in large part of quite recent growth

The author's avowed theme is the economic victory of the United States It gives a spice to the book and will commend it to American readers who may follow breathlessly the story of the rise and penetration of a flood of American capital all over the world ' Our weapons are money and machines But the other nations of the world want money and machines Our materialism, though not our power, is matched by theirs That is why our conquest is so easy, so inevitable " As to England, " She is an over populated, dependent, exposed island As a major world Power, her days are numbered "

One might remark, in passing, that this melancholy conclusion is not quite in keeping with the general thesis and the manifold and startling findings of the book From these we gather—and the author is constantly enforcing this conclusion—that the United States and Great Britain (meaning, of course, the whole British Commonwealth, so far as it acts as one) are waging a titanic combat for the mastery of the world They and we are in the foreground of the picture and the rest are almost nowhere If this be so, how can he at the same time represent Great Britain as fallen from the rank of ' major powers ' ? Which are the other ' major powers ' which have taken her place ?

This may, however, be considered rather as a debating point, it is the larger issues which call for most attention Looking at the facts rather from the world point of view, what strikes one most is the pervasion of the whole world by giant financial interests which are insistently acquiring and attempting to control the materials and means of life necessary for our modern civilisation It is on this side that Mr Denny's review is so enlightening, and in one sense so disquieting We see rubber, oil, chemicals, cables, radio communication,

air routes, shipping, being fought for and, so far as possible, monopolised by huge trusts and mergers in which from time to time nationalist animosities blaze out and national governments take a part, but which on the whole are governed by financial considerations This would be the conclusion of any fair minded survey of the multitude of facts which Mr Denny presents, and he admits it himself in the sentence quoted above So far as America has 'conquered' Britain, or any other part of the world, it is by virtue of her wealth, size, population, and collective resources, not by the exercise of any deliberately hostile act or intention This is why the constantly warlike language and analogies of the author are to be deprecated Economic motives, no doubt, had some place in the War, but it would be a wild misreading of history to regard them as the most important, and in the future a real war, arising from the economic war' described in the book, is still less to be expected If anyone is inclined to think this a piece of 'facile optimism', he should remember that practically all the trusts and mergers have money from many nations, that the two leading rivals, America and Great Britain, work side by side on many of them, and that the oil kings and rubber emperors, men like Sir Henri Deterding, are more and more international figures

Still, the facts are extraordinarily interesting and serious, the more so because they are mostly of such recent date most of the developments described are post War But though the facts are so complicated, two simple morals will be drawn by the plain, well-meaning man The first, that it is not an unmixed evil that there should be some competition between the purveyors of oil and potash and rubber and tin, things that are increasingly needed in a modern State That there should be an absolute monopoly would be quite intolerable The second, that the spread of world-wide financial influences makes more and more urgent the strengthening of a world authority superior to them—the League of Nations and cognate bodies, representing and reconciling the interest of all What the United States has done at home to curb the tyranny of trusts must be done internationally in so far as the trusts become strong enough to threaten the well-being not so much of rival governments but of the struggling consumers for whom they exist Some of the great interests mentioned, aviation, for example, and radio, would seem to be eminently suitable for international control.

F. S. MARVIN.

Human Speech.

Human Speech some Observations, Experiments and Conclusions as to the Nature, Origin, Purpose and possible Improvement of Human Speech By Sir Richard Paget, Bart (International Library of Psychology, Philosophy and Scientific Method) Pp xiv + 360 + 6 plates (London Kegan Paul and Co, Ltd, New York Harcourt, Brace and Co, 1930) 25s net

SIR RICHARD PAGET began his researches into the nature of human speech as follows " Being alone in London, confined to bed with a slight chill, and disinclined to read, it occurred to me to try and listen to the whispered resonances of my own voice, as I had begun to do during the War " He required no other apparatus than a pencil and paper, for, although without the gift of 'absolute pitch', he can produce notes of 812 and 966 vibrations per second by tapping his skull in certain places These he used as standards throughout his researches He listened with such intensity to his whispered vowels as to produce a feeling of sickness Gradually the power to recognise each resonance was acquired The first product was a chart of vowel resonances more complete than any hitherto produced

By adding plasticine, tubes of cardboard, glass and rubber, cork, clips, and other similar inexpensive means to his experimental equipment, Sir Richard Paget was able to accumulate the material for three Royal Society papers, which carried the whole matter much beyond the point attained by previous investigators, and are now recognised the world over as fundamental All the sounds of speech have been dealt with in the course of his work

'Sound, light, heat, magnetism and electricity' were the old pedagogic divisions of the science of physics the least of these, though named first by some freak of fortune, was sound Even the invention of telephone and phonograph failed to attract more than a negligible proportion of students into the domain of sound research War and peace, sound-ranging and talkies, have changed all that An army of investigators equipped with apparatus of the highest refinement is busy in America Their results have confirmed those of Sir Richard Paget We may be excused a certain pride and æsthetic pleasure in the elegant simplicity and genial intuition of our countryman, so truly in the tradition of our native scientific genius. We do not thereby

admit vicarious ascetic virtue in our financiers who leave our pioneer workers austerely devoid of the expensive equipment showered upon their colleagues abroad

It would seem that, in many branches of industry those who hold the purse strings are willing to plead safety first and relinquish our pride of place in industrial invention They are willing to pay heavy tribute to other countries particularly America and Germany for inventions frequently based upon the pioneer work of Englishmen The situation would be less deplorable if the money subscribed by the public to industrial undertakings were in fact always used with the maximum of economy and safety On the contrary it has recently been used especially in this particular field in so criminally careless a manner that no more is forthcoming at the present time

We may expect that so fertile a mind capable of tackling a very old subject with prodigality of invention and economy of means will range a good deal farther than the mere setting down of the facts ascertained We are not disappointed Sir Richard Paget s researches are for him a means to an end—not better and brighter talkies but the improvement of language and speech based upon a full understanding of its mechanism and origin Speech is effected by movements of parts of the oral cavity which movements our ears recognise even when the actual sounds transmitted to the ears as a result of them vary very much from time to time The oscillograph record of a word as whispered voiced or sung by various people will be very different but the oral movements are essentially the same

How do these movements arise? The theory which Sir Richard Paget has made his own (though foreshadowed by others whose work is here referred to very fully) is as follows the movements were originally descriptive gestures, analogous to those made by the more visible parts of the body in sign language, which probably preceded speech These movements tend to arise along with sign language, quite unconsciously. the schoolboy, painfully striving to write neatly, follows his pen with his lips and tongue We see the gestures of sign language with our eyes, which fail us in the dark, but we can see the gestures of our oral cavity with our ears hence the superiority of such gestures

This theory is worked out with skill, ingenuity, and a wealth of illustration, which make this part of the book absorbingly interesting The work of the only noteworthy and specific forerunner, Dr J Rae, is printed in full This is welcome for the original appeared only in a paper called *The Polynesian* published in Honolulu in 1862 and hence is not very accessible though most entertaining

The value and scope of Sir Richard Paget s researches confer upon the author every right to give us some advice as to how they may be turned to practical account Those in search of a commercial proposition may consider the construction of a talking automaton or robot which would have the greatest value for teaching purposes Teachers and students of elocution and singing will find abundant matter in the chapter on voice production Finally there is a strong plea for conscious effort towards the improvement of our language in every respect—form grammar pronunciation and orthography We are competent for the task now that we know so much about it physically and historically The endeavours of devoted and enthusiastic people to popularise artificial languages for international communication seem destined to make little further progress, while English continues to spread rapidly There can be little doubt that it will finally become the medium of international understanding and we shall be doing a great work in making it as perfect an instrument as possible

Sir Richard Paget appeals in his work for the development of a centre for the study of the relations of thought and speech such a centre already exists as he points out in the Orthological Institute under the direction of Mr C K Ogden and is engaged in investigating these problems and in applying the results to the simplification of English for practical international purposes Sir Richard Paget would have us go further with such pioneers and casting aside custom and tradition get down to fundamentals transform our language by conscious effort into a more efficient means of expression as well for the uses of art as for those of science and commerce

The book is enriched with other valuable features —a discussion of notation, a mathematical exposition of the double resonator theory by Mr W E Beaton copious references, an adequate index Altogether a worthy addition to the International Library of Psychology, Philosophy and Scientific Method, that bright star on the firmament of British publishing enterprise

Our Bookshelf.

Recent Advances in Preventive Medicine By Dr J F C Haslam With a chapter on the Vitamins by Prof S J Cowell (The Recent Advances Series) Pp viii + 328 + 6 plates (London J and A Churchill, 1930) 12s 6d

This volume of the series describes 'recent advances' which are so modern that many of them might more aptly be said to constitute new departments of preventive medicine The space allotted to each subject is so small that only a very condensed account can be given, but this is done without either obscuring the meaning or presenting an uninteresting catalogue of facts and theories The nine chapters which deal with different branches of hygiene contain information only acquired in the last five or ten years on subjects the very names and substances of which did not exist twenty years ago

Since matter of such recent date has been chiefly selected for treatment, the more gradual advances in other departments have of necessity been omitted Dr Haslam has included a notice of the difficult problems of practical eugenics and the various experiments which have recently been made He expounds the most diverse themes from infantile mortality and nursery homes to the methods of investigating the excessive mortality of compositors from consumption, and the means of acquiring active immunity to diphtheria and scarlet fever The causes and prevention of dental caries are well and judiciously discussed and the real knowledge gained clearly set out The effect of atmospheric conditions on health and their study by the use of the kata thermometer are interestingly discussed in 22 pages The effect of psychological and other personal characteristics on the incidence of industrial accidents is among the subjects considered in the survey Prof S J Cowell in 30 pages on vitamins gives a very lucid account of the rapid advance and definite knowledge attained in this still actively growing field of research

The book affords not only a pleasant means of obtaining a glimpse of so much that has been learnt of late in preventive medicine, but also provides a very useful list of books and papers from which more detailed information on the separate subjects can be obtained

Modifications in Indian Culture through Inventions and Loans By Erland Nordenskiöld (Comparative Ethnographical Studies, Vol 8) Pp v + 256 (London Oxford University Press, 1930) 18s 6d net

Baron Erland Nordenskiöld's "Comparative Ethnographical Studies" have confirmed rather than won for him a standing as the foremost authority in the study of the Indians of Central and South America His latest volume in the series has an added value in that it is a much desired contribution to the study of the 'diffusion' question, which relies upon an examination of detail and not upon generalised conclusions Incidentally and as a matter of secondary interest, several sections might serve as demonstrations of the method of technological study

Indian culture is here treated in various aspects The first section deals with Indian invention and discovery in the pre Columbian period, one of the most significant points being an apparent readiness to experiment in the utilisation of natural products In a lengthy list of such discoveries, maize, the sweet potato, manioc, tobacco, coca, and cocoa are the most familiar Perhaps the most remarkable and significant invention, however, is that of bronze, which, the author maintains, must be regarded as an element independent of the Old World This, however, is one only of a number of inventions which the author concludes must have arisen independently in the New and the Old Worlds In this connexion and in view of the discussion which has taken place on the origin of the Maya civilisation, it is remarkable that the Maya calendar and system of writing have no exact parallels elsewhere

As a whole, this volume is a valuable contribution to the study of a difficult problem It is only by such detailed studies as this that we are likely to arrive at the truth It serves to demonstrate that only a most exact comparison of detail can afford a sound basis of argument Generalised statements may appear to afford support for theory, but too often it vanishes when a more exacting search is made for correspondence in detail

(1) *Science and Mathematical Tables for Use in Schools* Arranged by W F F Shearcroft and Denham Larrett Pp vi + 33 (London Sir Isaac Pitman and Sons, Ltd, 1929) 1s

(2) *Cambridge Five Figure Tables* By F G Hall and E K Rideal Pp viii + 76 (Cambridge At the University Press, 1929) 3s 6d

(3) *Seven Place Natural Trigonometrical Functions together with many Miscellaneous Tables and Appendices on the Adjustment of the Engineer's Transit and Level, Area Computation, Vertical Curves, Simple Curves, and Determination of Latitude, Longitude, and Azimuth* By Howard Chapin Ives Pp v + 222 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1929) 12s 6d net

(1) This is a clearly printed set of four figure tables of logarithms, antilogarithms, natural and logarithmic sines, cosines and tangents, together with some formulæ and physical constants

(2) The main contents are logarithms of numbers from 1,000 to 9,999, natural and logarithmic sines and tangents for each minute of arc The tables are arranged on a novel and interesting principle The arguments are in descending order of magnitude, so that each tabular entry is greater than the following one This arrangement facilitates the formation of differences, since the numbers are in the most suitable position for subtraction The type is very clear and well spaced

(3) These seven place tables give six natural trigonometric functions for each minute of arc,

versed sines, external secants, chords, circular arcs, and miscellaneous tables, formulæ and appendices of interest mainly to surveyors and railway engineers It is rather difficult to see any reason for tabulating external secants (sec $x - 1$) in a book which already contains a table of secants No differences are given, and this, together with the closeness of the printing, makes the tables somewhat difficult to use L M M T

Field Book of Marine Fishes of the Atlantic Coast from Labrador to Texas, being a Short Description of their Characteristics and Habits, with Keys for their Identification By Charles M Breder, jr (Putnam's Nature Field Books) Pp xxxviii + 332 + 16 plates (New York and London G P Putnam's Sons, 1929) 15s net

THIS little volume, more or less of pocket size, is designed primarily to meet the needs of the amateur outdoor naturalist, its main purpose being to enable a worker with the minimum of technical knowledge quickly and easily to identify any species of fish likely to be found in the area treated The author therefore begins by defining what is meant by the term fish, and describes briefly their general manner of life A short chapter is devoted to descriptions of the various types of environment included in the region under survey, which extends from the cold boreal waters of Labrador through the temperate seas of the Atlantic seaboard of America down to the warm tropical waters of the Gulf of Mexico An offshore limit has been set at the twenty five fathom line, and the brackish water zone marks the shoreward limit up streams and estuaries The greater part of the book is devoted to analytical keys and descriptive matter Keys are given to enable the worker to place his fish successively in its correct order, family, genus, and species Further to facilitate identification, an outline drawing of nearly every species is given, with an appended short note on its range, habits, relative abundance, and average adult size

There is a fairly comprehensive glossary of technical terms and a short bibliography

Leçons sur la théorie des tourbillons Par Prof Henri Villat (Institut de mécanique des fluides de l'Université de France) Pp v + 300 (Paris Gauthier-Villars et Cie, 1930) 65 francs

PROF VILLAT'S treatment of vortex motion has both the virtues and defects which are usually found in French treatises on mathematical physics The mathematical treatment is clear and logical, and presented in an attractive style On the other hand, although the lectures on which the book is based were delivered at an institute founded by the Ministry of Air, we have scarcely any reference to experimental data There is one oasis in the desert of mathematical symbols (p 80), where we read that a cylinder moving in liquid is really found, in certain circumstances, to set up two series of vortices closely conforming to those calculated by Bénard With this exception, the book suggests that the author cares much for mathematical analysis and little, if at all, for real fluids However, if we accept his point of view, there can be no question as to the quality of the work After an exposition of the classical results, we have a good account of more recent work, in particular that of Bénard, Synge, Rosenhead, Caldonazzo, Riabouchinsky, and Lichtenstein The last chapter uses Oseen's integral equation to discuss vortices in a viscous fluid

H T H P

Opera By Richard Capell Pp 80 *Libraries and Museums* By Sir Frederic Kenyon Pp 79 *Banking* By W W Paine Pp 80 (Benn's Sixpenny Library, Nos 99, 100, and 108) (London Ernest Benn, Ltd, 1930) 6*d* each

THE provision of inexpensive 'libraries' is not a new feature in England Prof Henry Morley long years ago edited a 9*d* library of classical literature and a 3*d* library of general literature, in each case the volumes issued were standard works, mostly of earlier date than the nineteenth century The present library proceeds upon a different basis, seeking individual authors to deal with some special subject Mr Capell in "Opera" has an interesting theme, which in the earlier portion of the book is overloaded by a flamboyant style of writing which detracts from the pleasure that a reader may experience Sir Frederic Kenyon's remarks upon libraries and museums are well worthy of attention, and his rapid survey of the centuries is alluring But he is mistaken in stating that Merton College Library, Oxford, is a fifteenth century building, as it is fourteenth century Perhaps Mr Paine's "Banking" is the most engaging of the books under notice, his treatment is masterly in its presentation—in a manner truly captivating—of what might easily prove dry as dust to the lay public P L M

Horological Hints and Helps By F W Britten (Lockwood's Manuals) Pp xi + 327 (London Crosby Lockwood and Son, 1930) 7*s* 6*d* net

THIS volume is addressed more to the young practitioner than to the novice, as it assumes a certain minimum of actual acquaintanceship with horology, in the absence of which the book would prove difficult to follow That the author is proud of being his father's son is made pleasantly clear from the reference on the title page After dealing at sufficient length with general horological work, the remaining pages are distributed between watches and clocks That Mr Britten understands his subject from the dial plate and hands down to the very least screw is abundantly evident, but the book is entirely lacking in any graces of literary style It may be granted that knowledge is the quality to be preferred, but a work of art exhibits something more than mere technique, in truth, the latter is better shown by concealment There are numerous diagrams, and these would have been better had some idea of limiting dimensions been given, or had the amount of magnification been stated It would be difficult to select any one part of the book as being more valuable than any other, where all is so practical and masterly P L M.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

Stark Effect in the Ultra-violet Spectrum of Neon.

THE ultra violet spectrum of neon consists of the lines belonging to the principal series of the arc spectrum and the lines of singly and doubly ionised neon To obtain the Stark effect for these lines it is essential to increase the field strength for the lower members and the intensity for the higher members The spectrograph used was the Steinheil Q D type The field stength was determined from helium lines

It was found that sixty lines of the principal series are affected, and these practically include the most important lines As an illustration, the accompanying photographs are reproduced (Fig 1) Most of these lines are deflected toward the negative side, but six of them are deflected toward the positive Some of the higher members accompany the *sd* combination lines, which in turn are slightly deflected in the same direction as the associated principal series lines It is remarkable how these *sd* combination lines appear As the figure illustrates, the *sp* lines lose their intensities almost abruptly at about the same field strength as the *sd* lines appear, so that they can be recognised only with caution The discontinuity of the intensity (that is, *sp-sd*) shifts toward the upper part of the spectrum with increase of the maximum field strength as expected (the field strength being distributed in the same spectral length, the point corresponding to the same field strength would shift toward the upper part as the maximum field is increased) Another remarkable feature is that Pashen's $1s_2 - mp_1$ series suffers a change of sign (in the electrical deflection) at $1s_2 - 4p_1$ and then regains the original positive sign as m increases (for $1s_2 - 2p_1$, +)

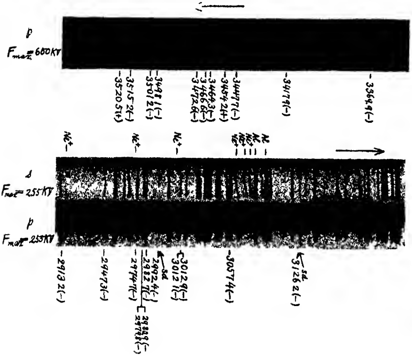

FIG 1

As regards the spectrum of ionised neon, it is a peculiar fact that the affected lines are very weak in intensity at low electric fields, and disappear altogether in high fields, the optimum field being in the interval of 120 250 k v per cm The presence of helium tends to reduce the intensity of the ionised neon in general, but with these affected lines it is very decidedly so, for with helium they totally disappear These lines are deflected to the positive side, and most of them accompany combination lines at the more refrangible side, the deflections of which are negative, the magnitude being nearly as large as that of the associated lines All the affected lines are grouped in the range λλ2915 3123 The non combination lines were recorded by Bloch [1] but were not investigated by the Bruin [2] system Tho lines considered by Bruin are scarcely affected and they, too, disappear in high fields The effect on the doubly ionised neon is uncertain at present

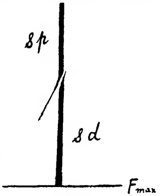

FIG 2

Both groups of the affected lines are only slightly polarised Details will be published in the Scientific Papers of this Institute

Stability in Soap Films

SOAP films exhibit a stability (permanence and mechanical strength) which is without parallel in films of water or other pure liquids which contract almost instantaneously to spherical droplets under the influence of surface tension In a letter to NATURE of May 31, p 815, Mr Green attributes this stability to "stratifications almost certainly pervading the whole film". This conclusion is directly opposed to the view, now widely held, that soap films have a 'sandwich' structure, as I have called it (*J Phys Chem.*, **34**, 263; 1930), that is, that they consist of a pair of surface layers adsorbed at the liquid/air interface and enclosing a layer of liquid, identical in composition with the channel of liquid around the boundary of the film and its rigid support (often called the Gibbs' ring) and with the solution from which the film was made In reply to Mr. Green's contentions,

there is no evidence that soap films have greater stability than is to be expected from the sandwich structure There is no reason to suppose that any degree of strength would result from the structure suggested by him, nor that such a structure exists except in abnormal and rare cases The evidence for these opinions is as follows

1 The number of bimolecular stratifications—of molecules of molecular weight 300 and occupying an area of 20 A U sq —which could be formed in a film 1000 $\mu\mu$ thick of 5 per cent soap solution is only 10 That is, the stratifications would be some 100 $\mu\mu$ apart It is useless to postulate "powerful but labile forces" to act over these distances, and the figures show that *no close packed arrangement of molecules in the interior of a soap film can account for enhanced mechanical strength* In any event, the thinning of a film which had such a structure would seem to require the destruction of the structure which is being suggested as essential for its continued existence! The conclusion that "the disruptive action of surface tension is overpowered by structural cohesiveness" takes no account of the origin of surface tension and its mechanism Disruption occurs under its influence when soap molecules are being pulled (by molecular attraction) from the surface layer into the interior at a faster rate than they can be replaced

I explain the checking of this disruptive tendency of surface tension by

(a) The lateral cohesion of the oriented molecules of the surface layers of the 'sandwich'

(b) The presence of a reserve of adsorbed solute just beneath the surface layer and ready to fill any vacant places in it

It is obvious that the "powerful but labile" forces postulated by Mr Green as acting between his stratifications must be an inward pull on the surface layer additional to surface tension, and therefore a serious source of weakness and not of stability at all

2 *There is no evidence that stratification of the interior of a soap film is of general occurrence* The term 'stratification' when applied to soap films has a definite significance (see Perrin, *Annales de Phys* (9), **10**, 165, 1918 P V Wells, loc cit (9), **16**, 79, 1921 Also Lawrence, "Soap Films", p 58, 1929) The sharp boundaries of coloured bubbles cannot be interpreted in this way, since the steps up in thickness are from 12 to 20 times that of the bimolecular layer The suggestion that these discontinuities result from aggregation of the molecules under the perfectly quiet experimental conditions ignores the fact that such conditions do not mean a cessation of the kinetic motions of the molecules in question It is more likely that these boundaries are due to colloidal soap threads which may well be responsible also for the persistence of inequalities of thickness, since their long flexible form will enable them to act as boundaries retarding free mixing

3 *Stratification of soap films containing a fluorescent substance is the formation of a new phase* We have no right to regard the interior of the soap film as in any way different from the solution of which it was once a part, *unless some definite change can be shown to have occurred.* No attempt has been made to explain the mechanism of stratification As we have already seen, a film 1000 $\mu\mu$ thick of 5 per cent soap solution can only yield 10 bimolecular layers, hence the maximum thickness of the resultant stratified film from one of this thickness should be 42 $\mu\mu$ (or less) Actually, however, brightly coloured stratifications will be observed 10 or more times as thick The extra solute comes from the Gibbs' ring and its extrusion is clear (see frontispiece of "Soap Films") It appears that, under the influence of light upon a soap film containing a fluorescent substance, molecules of soap separate at the face nearer to the source of illumination, these then link up with the surface layer of molecules, already oriented there, to form a bimolecular layer, the molecules being associated by their carboxyl extremities and therefore no longer soluble nor surface active Fresh solute will therefore be adsorbed, but only to be transformed in turn until the supply from the Gibbs' ring is exhausted The process is quite similar to the formation of Grandjean's terraces of liquid crystalline substances on an initially oriented layer of molecules I have not the space to go further into the matter—how, for example, the fluorescein can bring about this change—but there is no doubt that we are dealing with the formation of a new phase It is, in fact, a crystallisation I may add that a completely stratified film of the sort discovered by Perrin, in which the stratifications are close together and not separated by large distances as Mr Green's hypothetical ones are, has a mechanical strength apparently vastly inferior to that of a liquid film

This explanation of the rôle of the Gibbs' ring, coupled with the fact that all the stratified films hitherto studied have been very small ones, shows that Mr Green's suggestion that the 'stratifications' in large bubbles are due to the absence of disturbance from the Gibbs' ring is another argument against their being true stratifications at all

4 There is the final possibility of the occurrence of flakes in colloidal solution so that their presence in a soap film would not involve the formation of a new phase This, however, seems quite remote, since the characteristic form of the colloid particle in all soap solutions is the long thread, possibly the zigzag form and absence of radial symmetry of the molecule chain is the reason why colloidal lamellæ do not exist On the other hand, where soap separates from molecular dispersion by association of the carboxyl groups, the resultant form is always lamellar (Darke, McBain, and Salmon, *Proc Roy Soc*, A, **98**, 395, 1921 Also Lawrence, *Koll Zeit*, **50**, 12, 1930) It is clear then that the *ordinary soap solution contains no stratifications and that they only appear as a new phase*

I have no space to discuss blackening as the formation of a new phase, but I hope to deal with this and the whole question of the thinning of coloured films and to give an explanation of the hitherto inexplicable sharpness of the black boundary in a future publication

The Striated Discharge

IT is well known that the striation separation in the electrical discharge in gases varies with the radius of the discharge tube and the pressure of the gas The exact relation between these factors was first investigated by Wehner (*Ann der Phys*, **32**, p 49, 1910), who gave as a result of experiments with hydrogen and nitrogen the relation

$$S = C\,\frac{r^{1-m}}{P^m}$$

where S is the striation separation in mm, r the radius of the tube in mm, and P the pressure of the gas in mm of mercury C was a constant for both gases with a value of approximately 2, and m a constant which varied with the nature of the gas For hydrogen, $m = 0\ 53$, and for nitrogen, $m = 0\ 32$ Further experiments were carried out by Neubert (*Ann der Phys*, **42**, p 1454, 1913), in which he used hydrogen free from any impurities and found the same law to hold

The results of a series of experiments by us on the same topic, using different gases, have led to a modified form of the Wehner-Goldstein law In these experiments a set of five discharge tubes was arranged so that the tubes were all connected in series Each tube had plane aluminium electrodes nearly filling the cross section of the tube The internal radii were approximately 1 4, 2 6, 4 0, 5 3, and 6 5 cm respectively, and the tubes were all about 78 cm long The current density was kept the same in each tube

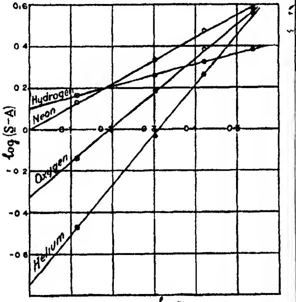

FIG 1

and the pressure adjusted until steady striations could be obtained in at least four of the tubes An Evershed and Vignolles direct current generator was used as a source of current The gases were pure except for contamination with mercury vapour from the McLeod gauge and from the mercury diffusion pump which was used to exhaust the system The five tubes were then all filled with the same gas at the same pressure The results of experiments with hydrogen, oxygen, helium, and neon indicate that the law for the variation of striation separation with the radius of the tube is given by

$$S = A + C\ r^n$$

where A and C are arbitrary constants depending upon the nature of the gas A typical set of results for these gases is shown in the accompanying diagram (Fig 1), where log $(S - A)$ is plotted as ordinates and log r as abscissæ The value of the pressure P was constant but different for each gas For hydrogen A is zero, thus agreeing with Neubert's result The values of n and C appear also to depend upon the amount of mercury vapour present The current density in each case was 0 28 milliamp /cm ^{2}, and the equations giving striation separation for each gas for the pressures used are given in the following table

Gas.	Pressure in mm Mercury	Striation Separation S in Terms of Radius of Tube r in mm
Hydrogen	0 21	$s = 1\ 26\ r^{0\ 52}$
Neon	0 16	$s = 0\ 95 + 1\ 1\ r^{2\ 1}$
Oxygen	0 07	$s = 1\ 2 + 0\ 48\ r^{1 \cdot 5}$
Helium	0 51	$s = 1\ 6 + 0\ 18\ r^{2\ 2}$

An interesting investigation by Prof John Zeleny on the variation of striation separation with pressure has just appeared in the *Journal of the Franklin Institute* for May In our experiments the pressure was kept constant, but the same law appears to hold for different pressures For example, in the case of helium the equations for the different pressures were found to be as follows

Pressure in mm of Mercury	Striation Separation in mm
0 38	$s = 1\ 5 + 0\ 55\ r^{1\ 5}$
0 53	$s = 1\ 6 + 0\ 64\ r^{1\ 5}$
0 67	$s = 1\ 4 + 0\ 23\ r^{2\ 5}$

A full account of this investigation will appear later, and further experiments will be done with tubes free from mercury vapour

Mortality amongst Plants and its Bearing on Natural Selection

THE interest for the theory of natural selection of the researches on the mortality of seedlings reported by Dr E J Salisbury (NATURE, May 31) is so great, as is, in all its aspects, the development of a quantitative ecological technique, that it seems important not to allow the interpretation of the new observational material to be prejudiced by the use of an argument which contains a concealed fallacy This argument could not be more briefly stated than in Dr Salisbury's words, "The mortality and therefore the operation of natural selection is almost entirely confined to the juvenile stages of development"

It may be recalled that this same argument was used by Wallace as a reason for rejecting the application of the theory of sexual selection to butterflies ("Darwinism", p 296) "In butterflies the weeding out by natural selection takes place to an enormous extent in the egg, larva, and pupa states, and perhaps not more than one in a hundred of the eggs laid produces a perfect insect which lives to breed Here, then, the impotence of female selection, if it exists, must be complete" Wallace, however, did not apply this argument to a second case to which evidently it is equally applicable, for he has no hesitation in advocating the development of *protective* coloration by the natural selection of adult butterflies (*ibid*, p 207)

I believe the most useful step in examining the nature of this fallacy is to realise that, when mortality is heavy, immature forms of different ages are not of equal value, in the purely objective sense that they will not be equally represented in the ancestry of future generations Knowing the rates of death and reproduction at all ages, it is possible to calculate the reproductive value, in this sense, at each age, and the course of this function for ages prior to the commencement of reproduction, is, in a stationary population, easily seen to be inversely proportional to the number living at each age If, therefore, starting from the seed, we have three stages of development, A, B, and C, to which 1 in 10, 1 in 100, and 1 in 1000 seeds actually attain, single individuals at these stages will be worth, in respect of their probable contribution to future generations, just 10, 100, and 1000 times respectively as much as the newly shed seed is worth The selective elimination of certain individuals at stage C is for this reason as effective in modifying the genetic constitution of the species as the selective elimination of 10 times as many individuals at stage B, or of 100 times as many at stage A, or of 1000 seeds in their initial condition

The concept of reproductive value seems to provide a powerful method of resolving many of the paradoxes which have arisen in Darwinian discussions. It is easy by its means to show in what circumstances, and for what reasons, such widespread assumptions as that the death rate is a more important selective agency than the birth rate, or that selection is most intense at times when the death rate is highest may be in fact very far from true. The prospect of determining the vital statistics of wild populations, with sufficient accuracy to establish the relative values of different stages of development, is one of the most attractive features of the quantitative method in these fields.

R. A. FISHER.

Rothamsted Experimental Station,
Harpenden, Herts,
June 2.

THE interesting and valuable letter of Prof. Salisbury on the subject of "Mortality amongst Plants and its Bearing on Natural Selection", which appeared in NATURE of May 31, cannot be allowed to pass without comment, as the issues which it raises are fundamental. Prof. Salisbury finds that amongst plants it is in the seedling stage that the unfit are eliminated and that there is no evidence that little peculiarities of form which are manifested only in the adult condition have any bearing on survival at all. What determines the survival of a seedling is its *vigour of growth*, not peculiarities of its morphology. Prof. Salisbury does not touch on the causes of these differences in vigour, and doubtless in every particular case a special investigation would be required to determine them.

My purpose in writing this letter is to direct attention to the fact that similar differences in vigour are to be seen in the eggs of animals and that some light has been thrown on the causes of these differences.

In a recent paper ("General Physiology of Development of Simple Ascidians", *Phil. Trans. Roy. Soc.*, Series B, vol. 218, 1930), Mr. N. J. Berrill, lecturer in comparative physiology in McGill University, describes *inter alia* his investigations into the causes of the differences of vigour among ascidian tadpoles. He finds that these are referable to the length of time that the eggs remain in the oviduct and the toxicity of the oveducal fluid.

Thus natural selection only weeds out the feeble and diseased and by no stretch of the imagination can be regarded as capable of giving rise to anything new.

In conclusion, I may mention a typical experience which we ourselves have experienced in the zoological laboratory of the Imperial College of Science this year. On two occasions we have had sent to us from Plymouth living *Echinus miliaris*. On both occasions the animals arrived alive, and males with active sperm and females with ripe eggs were found among them. On the second occasion we received the specimens within fifteen hours of their leaving Plymouth, and from them we have raised three vigorous cultures of exceptionally healthy larvæ. On the first occasion, however, through an error on the part of the G.W.R. officials, thirty-six hours elapsed before the specimens reached us. The eggs, though apparently normal, reacted feebly to fertilisation and admitted numerous spermatozoa, with the result that the vast majority had cytolysed by next morning. A few apparently normal larvæ were produced, but these all died off in about a week for no obvious reason but feebleness of constitution.

The Thermo-Electric Properties of Ferromagnetics.

IT has long been known that there are peculiarities in the thermo-electric power curves of the ferromagnetic metals. Fairly recently Dorfman, Jaanus, and Kikoin (*Zeits. fur Phys.*, 54, 277; 1929) have measured carefully the thermo-electric power of nickel against platinum over a range of temperatures in the neighbourhood of the Curie point of nickel. The variation is such as to indicate a fairly sudden change in the 'specific heat of electricity' for nickel at the Curie point. The magnitude of the change in the specific heat per electron, ΔC_e, is of the same order as the change in the specific heat per atom, ΔC_a, determined in the usual way. From this point it was concluded that the magnetic 'carriers' could be identified with the conduction electrons, although this does not fit in with other evidence.

For some time I have suspected that the sign of ΔC_e was given incorrectly, but the trickiness of signs is such that I have felt doubtful about my own conclusions. I have, however, recently had a letter from Dr. Dorfman (dated May 16) in which he tells me that a mistake was made in his paper. The magnitude of ΔC_e was given correctly, but the signs of ΔC_a and ΔC_e are opposite. This renders the previous conclusions untenable. So far as I know no explanation has been given of the modified result, of which I would like to suggest a tentative interpretation.

For approximate purposes, the specific heat of electricity per electron, C_e, may be defined as the change in specific heat of the metal due to the addition of one electron. The suggestion I wish to put forward is that the relation of the change in C_e in passing through the Curie point to the change in the atomic heat, C_a, depends on the number of electrons required per atom to convert the substance from a ferromagnetic to a non-ferromagnetic state, in which there is no additional 'magnetic' specific heat. If one electron per atom is required, ΔC_e should be equal and opposite to ΔC_a. More generally, if n electrons are necessary, the relation would be

$$n\,\Delta C_e = -\Delta C_a$$

Dorfman's results give for n the value 0·78 for nickel. If the nickel atoms were converted into copper-like ions, the assembly would be non-ferromagnetic. The result suggests, in agreement with other evidence, that less than one electron per atom is required to produce a non-ferromagnetic state. Moreover, if this interpretation is on the right lines, it indicates that the ferromagnetic properties of nickel are to be traced to a deficiency of electrons from complete groups rather than to an excess of electrons.

This brief outline will probably be sufficient to indicate the general nature of the suggested interpretation of Dorfman's experimental results.

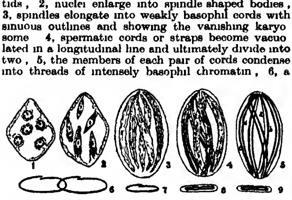
Multiple Spermatozoa and the Chromosome Hypothesis of Heredity.

IN 1928 I published (*Annals of the Natal Museum*, vol. 6, pt. 1) a short account of some observations indicating the production of more than one spermatozoon from a spermatid in the case of two Natal spiders, *Evarcha natalensis* and *Saitis leighi*. The conclusions then arrived at have now been confirmed by a more detailed examination of the spermiogenesis of an unnamed species of *Evarcha*.

The facts would seem to have considerable interest in their bearing on the hypothesis that hereditary

characters are transmitted by specific particles of chromatin incorporated in the chromosomes at definite sites

Very briefly to summarise the observations, we have, in the accompanying figure, 1, lobule of spermatids, 2, nuclei enlarge into spindle shaped bodies, 3, spindles elongate into weakly basophil cords with sinuous outlines and showing the vanishing karyosome 4, spermatic cords or straps become vacuolated in a longitudinal line and ultimately divide into two, 5, the members of each pair of cords condense into threads of intensely basophil chromatin, 6, a



pair of threads separating from each other and becoming spirally curved, 7, shrinkage of spermatozoon, 8, 9, formation of capsule Thus a lobule produces about twice as many spermatozoa as spermatids

The longitudinal splitting of the cords is far from being a regular process, sometimes it is not in the mid axis, and one member of the pair (5) is thin (*a*) and the other thick (*b*), while at other times the two members may be more or less similar to each other (*c*, *d*) In this connexion it must be added that in the genus *Saitis* there is a strong evidence that three, or even more, spermatic threads may arise from a single spermatic strap All the chromatin threads, whether relatively thick or thin, appear to form perfectly normal spermatozoa

From the very exacting nature of the chromosome hypothesis with the enigmatical genes arranged in serial order along the chromosomes, it would seem to be essential that the spermatic cords should split with mathematical accuracy into identical halves, but the processes outlined above are altogether inconsistent with any great precision in the subdivision of the chromatin substance in the formation of the spermatozoa

A detailed account of the observations will be published shortly, and in the meantime, granting their validity, it would be very interesting to hear how it is proposed to reconcile them with the current chromosome hypothesis of heredity

Natal Museum, Pietermaritzburg

Silicon Transformer Steel Residue

IN his book "Applied X Rays" Dr G L Clark publishes some very interesting photographs showing the connexion between the magnetic hysteresis loss and the grain size of 4 per cent silicon steels He takes the grain size to be inversely proportional to the number of spots produced under given conditions on a Laue photograph, and quotes a formula connecting this number with the magnetic hysteresis loss of the steel The fewer the Laue spots, the less is the hysteresis loss

Dr G Shearer, Mr C Wainwright, and myself some time ago obtained Laue photographs of samples of 4 per cent silicon transformer steels of different hysteresis loss which showed little difference in the number of diffraction spots, and what difference was to be observed tended to be contradictory to the above generalisation Further, no appreciable trace of orientation, which might have accounted for the anomaly, was found

Whilst the grain size must always be large for a steel of small hysteresis loss, it would appear that for closer comparison of magnetic value the straightforward interpretation of the Laue photographs can be misleading, and that other factors must be involved

Such a factor is suggested by the following preliminary account of an observation made in the course of a recent X ray study of steel residues, obtained by the method of Arnold and Read, in which the iron is removed by electrolytic dissolution The residues of six samples of silicon transformer steels, which, examined by the Clark method, gave anomalous indications of hysteresis loss, were investigated Three of these steels were good in that their hysteresis losses, measured at a maximum flux density of 10,000 lines per sq cm were only 1 19, 1 16, and 1 19 watts per kilogram respectively The other three were relatively bad with hysteresis losses of 1 78, 1 90, and 2 28 watts per kilogram respectively It was found that the residues of the bad steels gave a spectrum which was purely that of cementite, Fe_3C On the other hand, two of the good steel residues were amorphous, showing no diffraction pattern whatsoever, and the third gave only a few weak lines of some substance which was not cementite

It is suggested, then, that a difference like this will correspond to a difference in the value of the steel I have already shown that the state of subdivision of the carbide residues of steels is generally the same as the state of subdivision of the carbides when in the steel itself, so that the differences in aggregation of the particles observed by means of the X ray photographs of the silicon steel residues will correspond to similar differences among the carbides whilst in the steel It is hoped soon to pursue the matter further

Transmission of Potato Leaf-Roll

IN the course of experiments on potato leaf roll in progress at this College, proof has been found that *Myzus circumflexus* (Buckton) is an efficient transmitter of this disease There is also some evidence that another aphis, *Macrosiphum gei* (Koch), can transmit leaf roll feebly, but a definite opinion must await the completion of notes on the appearance of the progeny of infested plants

Myzus circumflexus, with us, has proved to be almost as reliable a transmitter as *Myzus persicæ* (Sulz), but there is a curious lag in the development of symptoms when the former aphis is used, so that plants infected with leaf roll by means of *M circumflexus* will still be in the 'primary' stage when those infected by *M persicæ* show rolling in lower as well as upper leaves Apart from the difference in the rate at which symptoms develop in infected plants, there is little to choose between the two species in their efficiency as transmitters

The discovery is of interest in several directions It corrects the growing tendency amongst plant virus workers to regard the relation of *M persicæ* to leaf-roll transmission as specific and unique At the same time, the difference in the response of a plant according to the species of aphis by which the inoculum is carried will tend to concentrate attention on the precise rôle played by the insect in virus transmission. I have been unable to find any record of the occurrence of *M circumflexus* on field potatoes in this country, so that, even if it does occasionally visit the

potato crop it is unlikely to be of much importance as a field transmitter of virus diseases in most seasons and most localities On the other hand, it has been recorded on *Hordeum*, *Avena*, and *Trifolium pratense* under field conditions, and this fact should be taken into account by workers who are attempting to maintain healthy stocks of potatoes in the field by isolating them in cereal crops or by intervening meadow land Theobald found it in great abundance out of doors in May, and quotes Laing as saying that the species breeds quite readily outdoor in mid summer Under glass house conditions it feeds voraciously on potato—whether sprouts, stem or leaves, and, with us, it has proved more prolific than either *M persicæ* or *Macrosiphum gei* on potato

Those facts and the ease with which the apterous viviparous female can be distinguished from other potato feeding aphides make it a valuable species with which to work on virus transmission Most of my work with aphis vectors has been carried out during the winter and spring months, and it is conceivable that summer generations of some species of aphides might vary in the efficiency with which they will transmit virus diseases May not this be a partial explanation of the negative results recorded by some workers when using species other than *M persicæ* ?

A Relation between the Continuous and the Many-Lined Spectra of Hydrogen

RECENT investigations on the continuous and the many lined spectra of hydrogen seem to show that there is some relation between the origin of the continuous spectrum and the electronic states of the term systems of the spectra of the hydrogen molecule We have often observed in our experiments that although the intensity of the continuous spectrum seems quite independent of the intensity of the atomic lines, certain band groups of the many-lined spectrum in the whole region of the visible are often strong when the continuous spectrum is intense In an ordinary discharge tube, for example, this continuous spectrum is produced with strong intensity at high pressure (5 8 cm of mercury), and is accompanied by the band groups of the triplet system of the hydrogen molecule in greater intensity than the other many lined spectrum According to our observations, most of them are classified as the transitions $2\,{}^3\Sigma - 3\,{}^3\Pi$, (Fulcher bands) and $2\,{}^3\Sigma - 4\,{}^3\Pi$

According to the interpretation of J G Winans and R C G Stueckelberg (*Proc Nat Acad Sci*, **14**, 867, 1928), this continuous spectrum originates in the transition from any one of the excited triplet levels to the unquantised ground state ($1\,{}^3\Sigma$) of this system Thus the above experimental fact suggests one relation between the continuous spectrum and the many lined spectrum of hydrogen and seems to favour the view of Winans and Stueckelberg After further experiments the results will be published elsewhere in detail

Siliceous Shells of Protozoa

IT is of course well known that some Protozoa (as Radiolaria and Heliozoa) have the hard parts siliceous, while others (as Foraminifera) have them calcareous Sponges show analogous groups In 1911,[1] when discussing the freshwater genus *Quadrulella* (Rhizopoda), I remarked · " In his recently published (1911) paper on the Rhizopods of the British Antarctic Expedition, Penard calls attention to the curious fact that while the square plates of *Q symmetrica* are siliceous, those of *Q irregularis* (Archer) are calcareous, and will dissolve in hot concentrated sulphuric acid He therefore inclines to agree with Awerinzew that the two animals are really generically distinct, and represent a case of convergent evolution " There has just been published a very interesting paper by Heron Allen and Earland [2] in which they describe a new genus (*Miliammina*) of Foraminifera with a siliceous test, represented by five species in the Antarctic But, in 1914, Chapman dealt with one of these species, calling it a new variety *arenacea* of the northern *Miliolina oblonga* (Montagu) The new form is said to be a siliceous 'isomorph' of the porcellanous *M oblonga* The question naturally arises whether in such cases we do have 'convergent evolution', as I postulated in 1911, or divergent evolution, the form of the shell being ancestral the material of it changed Heron Allen and Earland are a little ambiguous about the type species of their new genus I now formally designate as such *Miliammina arenacea* (Chapman), which they, for no apparent reason call *M oblonga* (Chapman)

University College
Gower Street London, W C 1

The Diffraction of X-rays by Vitreous Solids and its Bearing on their Constitution.

I WAS interested to see the statement, by Messrs J T Randall, H P Rooksby, and B S Cooper on the above subject in NATURE of May 22, p 458, that silica glass corresponds to either cristobalite or tridymite crystallites of average size $1\ 5 - 2\ 0 \times 10^{-7}$ cm This confirms the theory of the formation of glass I published in the *Transactions of the Society of Glass Technology* in 1919 (vol 3, p 282) I pointed out then that glass is not a super cooled liquid, such as phenol, which becomes solid on the addition of a small crystal of that substance, but is a solid colloid consisting of amicroscopic crystals, the formation of which is due to the high viscosity and degree of aggregation of the components in the fused state

The 1851 Exhibition Commissioners and their Work *

THE SIXTIES SEVENTIES AND EIGHTIES

IN the sixties seventies and eighties the Commissioners were occupied in promoting the usefulness of the Main Square of the ground they had reserved for purposes concerned with science and art Some of these may be noted as representing the breadth of view with which they regarded the trust committed to them

The Exhibition of 1862 proposed and carried through by the Royal Society of Arts occupied part of that southern section of the ground which was bought in 1867 by the Government and on which the Natural History Museum was built for the Trustees of the British Museum To the north of that area the central portion of the ground was let to the Horticultural Society for a period of years After that Society s occupation the galleries which the Commissioners had erected along the east and west sides were leased to the Government that in the east in 1879 for the India Museum—and that on the west in 1882 for the Science Collections From 1862 to 1871 the Commissioners co operated with the public in providing a representative memorial to the Prince Consort in a Hall forming a central point of union where men of Science and Art could meet —the Albert Hall The Hall did not in fact establish itself to this effect What we see to day in part—and soon shall see in still larger part—is rather the fulfilment of the wish expressed at the time by Her Majesty Queen Victoria *That the establishments then already placed upon the Estate as well as those that might be expected to come there should be considered as a whole forming the most lasting and worthy memorial of the Prince s untiring and unselfish exertions for the general good*

In the period during which the Commissioners had unoccupied ground within their Main Square they afforded facilities for many temporary measures for extending knowledge and for cultivating a desire for it To cite a series of international exhibitions there were 1883 The Fisheries Exhibition 1884 the Health Exhibition 1885 the Inventions Exhibition which included the permanent Science Collections mentioned above 1886 The Colonial and Indian Exhibition which included the permanent India Collections

Of loan collections the most pregnant was the 1876 Loan Collection of Scientific Instruments and Apparatus which was opened by Queen Victoria In 1882 they leased the Western Galleries to the Government for the Science Collections consisting at first mainly of objects placed in that Loan Collection and either given for the permanent collection or left as long term loans This collection was reinforced in 1883 by the addition of the Patent Museum collections The combination thus effected formed the nucleus of the Science Museum of to day

In 1879 the Commissioners had leased the Eastern Galleries to the Government for the India Collections

* Continued from p 932.

In this period the Commissioners had granted long leases at nominal rents for institutions that they considered pertinent to their aims To mention some of these 1872 The Albert Hall 1879 The City and Guilds Institute 1882 The Royal College of Music The Imperial Institute opened by H M Queen Victoria in 1893 In 1876 they had offered to the Government to provide a site and £100 000 towards the cost of buildings connected with science and arts and in particular for a Museum of Science This offer was declined in 1879 In 1888 they submitted a further offer in this sense and they pointed out that progressive appropriations of sites on their estate increased the urgency of the Science Museum question In 1890 the Government accepted this offer

TAKING STOCK AS AT THE END OF THE EIGHTIES

Let us take stock—moral and material—as at 1889 To the credit side we must place not merely the great achievements which are indicated in the foregoing paragraphs but also—what the Commissioners themselves had kept constantly in view—the influence these had had at long or short intervals upon the development of public opinion and of official activity The record of early results of this influence need not be detailed it springs to the mind as one thinks of the several points of departure From the remarkable intellectual and industrial success of the great adventure for which the original members of the Commission were recruited Britain at home and abroad reaped a wonderful widening of vision as to its own powers and possibilities together with a keen realisation of the activities and methods of its foreign neighbours From the material success of the Exhibition the Commissioners garnered *money* which they devoted to the promotion of aims in direct furtherance of the aims of the Exhibition itself They found themselves as it were in a position with a wide outlook over a half developed area They determined to stabilise their position so that it could be held and used as a centre of influence for generations to come They watched for good openings in the wide stretch of the interests of science the arts and the industries Their material resources were but trifling in proportion to the possibilities of their indirect action They could do effective work only by pointing to fertile areas for public activity by illustrating methods of improvement and by tempting the strong to put their backs into the work They themselves could to some extent explore but only in a very small way could they act as pioneers They could point to illustrations of fertility which their exploration had disclosed or their pioneer work had proved They must leave to others its development

In their Sixth Report (1878) the Commissioners recall that their surplus (1852) was £186 000 and they show that between 1852 and 1878 they had contributed to public purposes sites buildings etc to the value of nearly half a million They state

that the land in their possession or soon to fall in, would, if cleared, possess a market value as building land exceeding a million sterling At the same time, however, they had considerable liabilities To buy out the interest of the Government in the land purchased jointly, the Commissioners had to supplement their available funds by borrowing, in 1859, £120 000 at 4 per cent, then in 1860 they borrowed £50,000 in connexion with the development of the "Main Square" This debt was reduced or increased at intervals as the development of the estate proceeded and as the financial results of their temporary activities varied In 1878 it was £155,000, in 1889, £134,000 (By 1891 it was reduced to £24,000)

AIMS CARRIED FORWARD FROM THE 'EIGHTIES TO THE 'NINETIES

Some items in the earlier records of the Commissioners bear directly on their activities in their second forty years Thus, in June 1876, they received a memorial from the president and fellows of the Royal Society urging the establishment of a Museum of Science The Commissioners themselves had submitted to the Treasury in the same month an offer of substantial co operation in this project, but no effective progress ensued As mentioned above, this offer had been declined in 1879

Next the Commissioners were assailed by the cry 'Divide'—divide the possessions committed to their trust In July 1877 they received a deputation of municipal representatives from provincial boroughs in England and Wales urging the realisation of the funds of the Commission to as great an extent as possible and the distribution of the proceeds of this realisation in grants to provincial museums Mr Joseph Chamberlain introduced the deputation and the Prince of Wales (afterwards King Edward), chairman of the Commission, asked Lord Granville to reply It was a reasoned reply—*in the negative* Towards the end of that reply it was stated that the Commissioners aimed rather at establishing scholarships (This interesting, and critical, interview is reported in detail in Appendix 'S' of the Commissioners' Sixth Report, 1878, and the subject is fully discussed in that Report)

The establishment of scholarships then forecast was held over until the Commissioners could make a sufficient reduction in their mortgage debt to set free an adequate surplus of income In 1889 they reported that they were in a position to allot for scholarships an annual sum "not less than £5000"

1891–1930

Science Research Scholarships—The Commissioners established their scheme of science scholarships in 1891 It had been prepared with great care, and it soon proved itself well and wisely conceived This scheme has been outlined in the opening section of these notes

In certain other fields the Commissioners have endeavoured, by such schemes as they could afford, to meet particular difficulties of the time They thus initiated

Industrial Bursaries in 1911, to enable well qualified university students of limited means to enter employment in industries which, at the outset, would entail costs greater than their means could meet The Commissioners award these bursaries by selection based on the reports of the university or college authorities as to the qualifications of the men they recommend

Post-Graduate Naval Architecture Scholarship in 1911, similarly awarded on the recommendation of the Institution of Naval Architects

Art Scholarships, 1912—the Rome Scholarships—administered by the British School at Rome, These are awarded by competition in London, and are tenable for three years in the School at Rome Three are offered at each annual competition, each scholarship is of value £250 per annum, and is tenable for three years at the School at Rome To provide suitable conditions in Rome for the studies and practice of their scholars, the Commissioners have co operated with others in the provision and maintenance of the British School at Rome

Throughout this period, successive developments in science, art, and industries led to expansion of the field, intermediate between education and practice, in which the Commissioners found it to be their opportunity, and indeed their duty, for the time being, to supplement other restricted resources or facilities available To day, four fifths of their ordinary income, which is limited, is devoted to such purposes

A 'LOCALITY' AND ITS BUILDINGS

Yes, Locality again Their own baby born nearly eighty years ago—"Vision" his father his mother 'Surplus' His foster parents—as usual in these days—an incorporated body, would fain see him functioning to the full of his inherited ability The public he was born to serve, proved tardy in recognising his inherent powers to serve them Generations of trustees have tended, watched, and worked for his development For this they required understanding and help alike from the State and from the public In the opening years of the present century these came in with good effect To day the omens are good, and it is not too much to look for great progress in the course of the 'thirties

DEVELOPMENT AFTER 1890

In 1891 the Commissioners had sold to the Government—at much less than its value, but "for purposes of Science and Art"—a key section of their "Main Square" The opening century found this eligible site in much the same condition as did 1891, but soon the Government had put in hand a building to accommodate the Physics and Chemistry Departments of the Royal College of Science, the Science Library, and two galleries for the Science Museum In 1905 the Government appointed a Committee—with an experienced and energetic member of the Royal Commission as its first Chairman—to consider the Royal College of Science and Royal School of Mines, present and future, as to staff, buildings, and equipment

The outcome of this—made possible by liberal support from generous donors and from private funds for buildings and from the Commissioners as to sites—was the Imperial College of Science and Technology The new College was constituted by incorporating in this single institution the Royal College of Science, the Royal School of Mines, both Government institutions, and the Central Technical College The last named had been established by the City and Guilds of London H M King Edward VII laid its foundation stone in 1909

The terms of the charter of the Imperial College showed that it was conceived as an institution with such freedom of action as would enable it to react quickly to developments of outlook, alike in science, in industry, and in methods of training The Commissioners welcomed the new college as one that would be in a strong position to promote the organisation of advanced education and research in science as applied to industry, and they devoted to its use the unoccupied sites on the south side of Prince Consort Road This allocation of sites did not interfere with any institution already on the area

BUILDINGS

The erection of the first block of the new building for the Science Museum was in progress in 1914, but was then interrupted It was resumed after the War, and the new building was opened by H M King George V in 1928

Operations have now begun for the erection of the new Museum of Practical Geology and headquarters of the Geological Survey This building will be contiguous to that of the Museum of Natural History and to that of the Science Museum Its completion will bring the Geological Survey and Museum close to the Royal School of Mines, which was first opened under its wing in Jermyn Street in 1851

On the Prince Consort Road section of the "Main Square" there now stands—at the east end, the Goldsmiths' Company's extension of the City and Guilds' Engineering College, and, continuous with that, the block devoted to geology and specialised sections of the Royal School of Mines This combined block of buildings was opened by H R H the Duke of York in 1926 Then to the west—beyond the Royal College of Music—there now stands the first part of the Chemical Technology Department of the Imperial College On the north side of the road, and facing this last, is the Students' Union and the Botany Department of the College On the southern transverse road of the "Main Square"—Imperial Institute Road—the central feature of the north side is the Imperial Institute itself The eastern part of that building is occupied by the headquarters services of the University of London Facing this, on the south side of the road, is that block of the Imperial College which houses the Physical and Chemical Departments and, in the centre, the Science Library, in connection with the Science Museum

The central part of the northern portion of the "Main Square" is largely occupied by buildings of a temporary nature, but the main lines of utilisation, as a whole, are now determined by the permanent buildings in being or in course of erection

The Victoria and Albert Museum, the Natural History Museum, the central block of the Imperial College, the first section of the new Science Museum, were all built by the Government on land bought, on favourable terms, from the Commissioners The new Geological Museum is in course of erection on the same section of the ground

It ought to be noted that the methods of construction used in the buildings of recent years make it relatively easy to transform interiors so as to meet changes of requirements as times change

SUMMARY

Let there be no misunderstanding While every forward step referred to in these notes has had a definite relation to the aims the Commissioners maintained through the decades, their expenditure in promoting the realisation of these aims has been but trifling in proportion to the costs of converting aims into practice Their influence has been essentially in the direction of initiation, of nursing, of demonstration on a small scale, and of affording to others an opportunity of trying out this or that idea For causes in which they firmly believed, they have not failed to continue their assistance through many years when other support failed to materialise Again, when a scheme seemed to have done all it could at the time, they discontinued demonstration and waited and watched

Their primary and their large aim was the development of 'system'—'system' in the sense in which they used the word *after* their first Report—the sense in which it is used in these notes The development and natural application of 'system' in this sense has been carried on and is being carried on by the *State*—not by the Commissioners In all major causes none but the State *could* carry it out

The speech from the Throne at the opening of Parliament, 1852–53, contained the following passage

"The advancement of the Fine Arts and of Practical Science will be readily recognised by you as worthy of the attention of a great and enlightened nation I have directed that a comprehensive scheme shall be laid before you, having in view the promotion of these objects, towards which I invite your aid and co-operation"

Following on this, the question of extending "a system of encouragement to local institutions for Practical Science" was taken up by the Government The Department of Science and Art was established in 1853 and the administration of Schools of Design, which had been established previously, was transferred from the Board of Trade to that Department Under the Department of Science and Art and, from 1903, under the Board of Education, which absorbed it and could administer its services on a broader basis and with a greater measure of central and local assistance, art, science, and technology became essential elements in national administration Government departments and local authorities, the University

Grants Committee, and the Universities have co operated in promoting a full development of 'system' From time to time the Commissioners have provided aids for able students at critical points, and they have already found it possible to move upward one of their scaling ladders

The Royal Commission has been, in its years, prospector, promoter, patron—patron in the cen turies old sense of extending wise guidance and limited assistance to persons or projects that appeared capable of furthering science or the arts, or of stimulating inventions or industries In the nature of things the ideas of the Commissioners have occasionally been too much in advance of the time to secure effective response Yet, when prospects improved and the idea still seemed good, it was tabled again with any modification that seemed desirable

It has been so with the realisation of all that was implied in their aim—a Locality—the establishment of varied central institutions in the area pegged out nearly eighty years ago The realisation of this part of their aim has been slow, and time has altered the conditions—alike as to pur poses and as to methods The substantial ele ments are taking shape, but it is fully realised that they must retain elasticity

F G OGILVIE

Progressive Agriculture

AN unusual and interesting example of successful co operation between industry and agricul ture is portrayed in the jubilee volume issued to commemorate fifty years' work of the Blanchisserie et Teinturerie de Thaon,* in the Vosges After the annexation of Alsace and Lorraine, France found herself bereft of several of her most im portant bleaching establishments, and in 1872 a society was formed to establish the industry at Thaon in the Vosges, M Armand Lederlin being installed as the first director The difficulties to be overcome were great, as the selection of the site had to be largely determined by the presence of abundant water free from chalk and iron, so essen tial for bleaching purposes This was the first industry to be established in a purely agricultural area, and, from the beginning, it has also been the centre of agricultural demonstrations seeking to aid the peasants and workmen to get the best results from their land The success of the venture was primarily due to M Armand Lederlin, an impassioned agriculturist and a great industrial worker, whose work was carried on by his son, M Paul Lederlin, who succeeded him as director in 1909 Their endeavours have raised the status of a little country village, numbering only 555 inhabitants in 1870, to an important township of 8000 people, prosperous in industry and also in agriculture

After 1903 many other allied establishments were acquired, until at the present time about ten thousand workpeople are employed, dealing with some two million metres of material per day of eight hours The Thaon Blanchisserie is probably the most powerful firm in Europe for the treatment of textiles Throughout its history a very close association has been maintained between the heads of the firm and local social and municipal life Housing problems, questions of public hygiene, the moral and intellectual development of the personnel, libraries, insurance, and organisations to reduce the cost of living, represent but a few of the activities which are supported and encouraged by the Blanchisserie

* Hoffmann, P, et Deboffe, J (1930?) Cinquante ans de travaux sur l agriculture et sur l'horticulture, 1877-1927 (Paris J B Baillière et Fils)

Before the foundation of the firm, the chief industries of the district were cattle raising and potato growing, a little oats and rye also being cultivated M A Lederlin was inspired by the work of the Rothamsted and Woburn Experi mental Stations in England, and of M George Ville in France, to strive to introduce the new ideas of the utilisation of chemical fertilisers for the improvement of crops, with the view of in creasing the prosperity of the district His aims and interests were primarily local, being intended to determine what varieties of agricultural plants were most suited to the district, but the results ultimately attained wider significance as the scope of the experiments extended The jubilee report recently issued is intended to prevent the results of the earlier experimental work from falling into oblivion, and generous support from the Blanchisserie has facilitated the reproduction of many tables and photographs

From 1879 until 1919 continuous agricultural experiments, carefully laid out, were carried on by M Armand Lederlin, and when he gave up the work by reason of age his son proceeded to carry on another series of somewhat different scope The aim is still to be useful to the Department of the Vosges, and the produce of the plots is sold to the personnel at prices often below the cost of production The chief immediate aim is now to improve cattle and crops by numerous experiments on selection and acclimatisation In connexion with the experimental farm, potatoes are the most important crop, for they are well suited to the soil and are also the source of the starch of which so much is used in the industry, the whole production of 2000 tons of potato starch per annum being absorbed by Thaon and its daughter establishments

Unsuccessful attempts have been made to establish another potato, *Solanum commersoni*, which provides edible aerial parts suitable for cattle food, and comes up year after year without replanting, from portions of the root left in the soil There is also a model dairy farm, with land specially cultivated for cattle food, a horticultural society with a very high standard of production, nurseries for raising conifers and deciduous trees for street

planting, and apiaries to encourage local beekeeping, while laboratories have been equipped to deal with the various chemical and biological problems associated with plant growth

The latter part of the report gives a detailed account of the results of the experiments An interesting feature is the agronomic soil map of Thaon, showing the areas lacking in certain essential plant nutrients, with some land containing too much nitrogen In this connexion is given a detailed table of the necessary manuring for various crops in different parts of the Thaon area Thirty-seven per cent of the whole area is in woods and forests, the rest being chiefly potatoes, with some wheat, oats, beetroot, and carrots The experiments on these crops embrace tests on variety, adaptation and acclimatisation, transmission of disease by seed, problems of selection and the degeneration of species, as well as the effect of manurial treatments In the latter connexion the action of disinfectants and accessory elements, such as sulphur and manganese, is receiving attention

The problem of weed eradication has been dealt with experimentally in this district, as charlock is a very serious menace to the crops Many sprays have been tried out, the results varying as usual with the weather, but excellent results and increased crops are claimed from the use of sulphuric acid, as much as thirty five per cent increase over the control being obtained Special systems of crop rotation are also suggested to mitigate the pest

The value of the agricultural section of the report would have been much enhanced if the conclusions from the many years' experiments had been collected and summarised, as it is generally necessary to go laboriously through the work of several years to gain information on any special point of interest Apart from this, the authors are to be congratulated on the production of a volume setting forth so clearly the working out of a sociological problem which offered special and unusual difficulties that have been successfully overcome by MM Armand and Paul Lederlin, with the co-operation of their staff W E B

Obituary

PROF G N STEWART

NEWS has been cabled from Cleveland, Ohio, of the death of George Neil Stewart, the well known physiologist Born in 1860 in London, Ontario, whither his parents had temporarily migrated from Lybster, Caithness, Stewart, while yet a child, was brought back to Great Britain He entered the University of Edinburgh in 1879 and graduated M A four years later with honours in mathematics, having meanwhile acted as assistant to Tait, the professor of physics During the session 1883–84 he was Mackay Smith Scholar and in 1887 received the degree of D Sc But physics did not hold Stewart for long He turned his attention to medicine and graduated M D in 1891, receiving a gold medal for his thesis Then followed a year's post graduate study in Berlin, after which Stewart was appointed senior demonstrator of physiology at Victoria College, Manchester In 1889 he became George Henry Lewes student in physiology at Cambridge, a position which he held until 1893, meanwhile acting as examiner in physiology in the University of Aberdeen and taking the then recently established Diploma in Public Health of Cambridge Several months during 1892 were also spent in the physiological laboratory in Strasbourg

Migrating in 1893 to the United States, Stewart spent some months as a voluntary research worker with Prof Bowditch at Harvard University, who then nominated him for the chair of physiology at the Medical School of the Western Reserve University, Cleveland, Ohio, which was one of the first of the medical schools west of the Alleghany mountains to abandon the proprietory system, establishing in its place a full-time staff in the laboratory subjects During the next nine years, Stewart found in Cleveland every opportunity to develop his subject both in teaching and research, the first evidence of his success being the publication in 1895 of "A Manual of Physiology with Practical Exercises" It can truthfully be said that his admirable book marked an epoch in the teaching of physiology, for it succeeded in showing how formal exposition could be interwoven with practical work The student of medicine under Stewart learned his physiology by doing experiments which were carefully chosen and planned so as to form the basis for the more or less informal lectures which were grouped around them Many of the practical courses in experimental physiology in the American schools are patterned on those outlined in Stewart's book, which passed through eight editions, of which the last appeared in 1918 It was largely through Stewart's influence that Western Reserve Medical School was among the first to follow the example of Johns Hopkins in raising its entrance requirements to three years in an academic college, thus making a combined arts and medicine course of seven years' duration This scheme in a somewhat modified form has since been adopted by the majority of medical schools in America

In 1903, Stewart was called to the University of Chicago to succeed Jacques Loeb in the chair of physiology, but here he stayed for only four years, being enticed back to Cleveland to organise and direct the department of experimental medicine which was established in memory of H K Cushing, whose son, Harvey Cushing, is the well-known professor of surgery in Harvard In this position Stewart found full scope for his untiring and painstaking research work in various fields of experimental medicine, the results of which have appeared from time to time in numerous papers, published mainly in the *American Journal of Physiology*, the *Journal of Pharmacology and Experimental Therapeutics*, and the *Journal of Experimental Medicine* These papers along with those of his associates have been issued in eight volumes (1911–1926) of

"Collected Papers from the H K Cushing Laboratory for Experimental Medicine, Western Reserve University" In 1920, Stewart was honoured by receiving the LL D of his Alma Mater

It would occupy too much space to give here an account of the many problems to the solution of which Stewart and his pupils have made valuable contributions His earliest work, influenced by his training in physics, concerned the electro physiology of nerve and the application of Talbot's law Then followed researches on the nerves of the heart and the circulation time, the latter being really pioneer work Attracted by the development of knowledge concerning the physical chemistry of solutions, Stewart then conducted numerous investigations bearing on the mechanism of the action of hæmolytic and agglutinative agents and the problem of permeability of animal cells The results of these researches were published in a monograph in 1909 ('The Mechanism of Hæmolysis with Special Reference to the Relations of Electrolytes to Cells")

Desiring to contribute to clinical medicine something which might be of assistance in the precise diagnosis of circulatory disturbances, Stewart elaborated (between 1910 and 1915) an ingenious calorimetric method for measurement of the rate of blood flow through the hands and feet, and with this he made numerous observations on hospital patients About 1918 were started researches on the functions of the adrenal glands, which occupied his attention until his death

Stewart was induced to enter this field because of the extravagant claims which were then being made concerning the relationship of the internal secretion of the adrenals to arteriosclerosis, diabetes, and various other diseases and conditions of the body With great experimental ingenuity and meticulous care, Stewart, with the assistance of Rogoff, proceeded to investigate the conditions in animals under which increased secretion of epinephrine occurs This work led him to conclude that epinephrine does not represent an internal secretion in the ordinary sense, but is rather of the nature of a metabolic by product, and that variations in its secretion into the blood are not of the physiological significance which others have assigned to them He denied, for example, that conditions of emotion, fright and fear in animals, are associated with significant variations in the internal secretion of this substance As the work proceeded, it became more and more evident that it is the cortex rather than the medulla of the adrenal gland that is of real physiological significance Whereas all of the medullary tissue could be destroyed without significantly affecting the well being or the behaviour of the animal, destruction of the cortex as well led ultimately to death, although not until after a much longer period than had hitherto been supposed Convinced that the cortex must produce an internal secretion which is essential to life, its deficiency being the cause of the symptom-complex known as Addison's disease, Stewart during the past few years sought for methods by which extracts could be prepared that would prolong the lives of adrenalectomised animals and prove of value in the treatment of adrenal disease in man

By those who knew him intimately, Stewart was greatly admired both as a scientific worker and as a man of broad sympathies and deep culture His quick wit, his remarkable memory, and his eloquence made him a most interesting lecturer and a notable figure in society meetings Although domiciled for more than thirty five years in the United States, he remained a British citizen, and during the earlier years of the War spent several months in England and in France seeking for an opportunity to do service for the allies

Stewart leaves behind him a widow and four children, who may rest assured that their grief is shared by the many who were fortunate enough to have him for a friend J J R MACLEOD

MR A F R WOLLASTON

ALEXANDER FREDERICK RICHMOND WOLLASTON, who died in his rooms at King's College, Cambridge, on June 4, shot by one of his pupils in a moment of insanity, was the son of George Hyde Wollaston, for many years a master at Clifton College He came of distinguished parentage Through his mother he had kinship as grandson and nephew with the artists George and W B Richmond from her he inherited a love of good music and painting and literature, and unerring taste On his father's side, the name and family has been famous for two centuries and more, as the 'Dictionary of National Biography" shows Chief in the list there given are the brothers Francis and William Hyde Wollaston, the former was his direct ancestor

Wollaston was born in 1875, and went from Clifton to Cambridge and the London Hospital, where he qualified in 1903 Many friendships were formed in his university days, among them one which decided the course of his life Alfred Newton, professor of zoology, Wollaston's senior by some forty five years, recognised his exceptional gifts and encouraged him to become a naturalist explorer All the activities of his student years combined to fit him for this Besides his medical qualifications he had acquired experience as a traveller and mountaineer, and a wide range of knowledge of living creatures and plants As a field naturalist he was in the first rank, and he possessed a tall spare frame capable of great endurance

Wollaston's reputation among geographers and naturalists was established by the two expeditions, organised by the British Museum and the British Ornithologists' Union respectively, to Ruwenzori and to New Guinea, and by his delightfully written narratives of them [1] On Ruwenzori he twice climbed peaks (one of which now bears his name) which he supposed with good reason to be the highest of the range When the expedition came to an end, he and Carruthers made their way southward to Lake Tanganyika, thence westward to the upper waters of the Congo, and voyaged down the river to its mouth A curious common feature of

the two expeditions was the discovery in each of a race of pygmies The results of the New Guinea expedition were disappointing, through no fault of the explorers Wollaston returned there in 1912 with a party led by himself, the outbreak of the War frustrated his plans for a third expedition, and our hopes for a new book of travel from his pen His "Life of Alfred Newton", at which he had laboured for several years, could not be published until 1921, and was then reduced to half its intended size

For his work in the War—in the northern patrol, under Smuts in East Africa, on a monitor, and on the Murman Coast—Wollaston received the Distinguished Service Cross In 1920 King's College elected him a fellow, and for a time Cambridge was his home But two more journeys lay before him He went as medical officer and naturalist on the first Everest expedition, and in 1923 he married, and set out with his wife to an almost unknown mountain range in Colombia Quiet years followed He served on the council and later became honorary secretary of the Royal Geographical Society, he had been the recipient of the Society's Gill memorial medal and the Patron's gold medal in 1914 and 1925 At the time of his death he had been tutor of King's College, Cambridge, for eighteen months

It is difficult to imagine a man with greater power of inspiring affection and confidence than Wollaston, he was so completely honest, sensible, and straightforward His wanderings were over, they had brought him fame and honour, their dangers had passed by him unharmed Blessed in his home-life and with friends innumerable, all the signs foretold for him many years of peaceful happiness

H W R

[1] "From Ruwenzori to the Congo, a Naturalist's Journey across Africa and Pygmies and Papuans, the Stone Age to day in Dutch New Guinea It is not out of place here to refer to the admirable appreciation of Wollaston in Henry Newbolt's Book of the Long Trail

---

WE regret to announce the following deaths

Prof W H Bristol, formerly professor of mathematics at the Stevens Institute of Technology, Hoboken, and inventor of numerous recording instruments for pressure temperature, and electricity, as well as of devices for sound amplifying, and talking motion picture apparatus, aged seventy years

Dr Allerton S Cushman, founder and director of the Institute of Industrial Research in Washington, and author of papers on corrosion and other chemical subjects, on May 1, aged sixty two years

Dr George Dimmock of Springfield, Mass known for his contributions to entomology, on May 17, aged seventy eight years

Dr J Arthur Harris head of the Department of Botany of the University of Minnesota, whose interests lay in ecology and biometry, on April 24, aged forty nine years

Dr Charles F McKenna, president in 1910 of the American Society of Chemical Engineers, on April 25, aged sixty eight years

Dr Thomas F McKinney, from 1908 until 1928 professor of mathematics in the University of South Dakota, known for work on continued fractions and the theory of equations, on April 14, aged sixty five years

News and Views

ON June 19, Dr and Mrs Robert Mond entertained a large number of distinguished guests at a dinner held at the Savoy in honour of Sir W M Flinders Petrie, who this season has completed his fiftieth year of exploration and research in Egyptian archæology Addresses and messages of congratulation and good will were received from the British Academy and other scientific and learned bodies It is no exaggeration to say, however, that outside the immediate circle present on this occasion, the whole world of those who are interested in humane studies now offers its tribute of veneration to a great scholar and research worker To the historian of the future, Sir Flinders Petrie will not merely rank with the one or two great and familiar names in Egyptology, he will stand out as the first to set the study of Egyptian archæology upon a scientific basis—one whose work has served not only as a model and guide for all subsequent research, but also has made ancient Egyptian culture live in the eyes of a modern generation The system of sequence dating which he elaborated as a classification and a means of assigning to their proper horizon the material objects of Egyptian culture from predynastic times to the close of its existence as a separate entity in the ancient world, equally with the order and method he exemplified in his own excavations and inculcated and demanded in the work of others, have laid archæological studies under a debt to him which it is difficult to estimate By maintaining steadfastly the point of view of the anthropologist he has kept Egyptology in relation with wider studies and saved it from the aridity of the specialist outlook with which it was threatened

IN 1875, as a young man of twenty two, Sir Flinders Petrie began the study of the ancient monuments of Britain, and by 1880 he had published his "Inductive Metrology" and "Stonehenge" From 1880 onward he visited Egypt annually, publishing the reports on his excavations with minutely conscientious documentation and after the minimum of delay consistent with careful preparation His discoveries range from predynastic graves to the Greek settlements of Naukratis and Daphnæ—Koptos, Naqada, Abydos Lahun, and many more, a lengthy list now landmarks in Egyptian archæology Egyptian literature, art, social life, technical methods and appliances, magic and religion, in fact all sides of Egyptian life and culture, have been reviewed by his pen, and finally the results of his work were gathered together in his monumental history of Egypt As workers in other fields well know, his interest in the problems of and methods of general archæology has been kept keenly alive Further, it is not only by his own researches that Sir Flinders Petrie has served archæology At home as Edwards professor of Egyptology at University College, London

—a post which he accepted in 1892—and in the field by practical instruction and supervision he influenced and moulded generations of research workers. In 1894 he founded the Egyptian Research Account, which became the British School of Archæology in Egypt in 1905. Through this organisation his excavations in Egypt continued until a few years ago, when local circumstances made it advisable that the field of operations should be removed to Palestine. In the organisation and administration of his research Sir Flinders has been loyally assisted since his marriage in 1897 by Lady Petrie. He received the honour of knighthood in 1923, and his work was further commemorated by the foundation of the Petrie gold medal, which is awarded for outstanding achievement in the study of general archæology.

IN the last issue of the *Royal Naval Engineering College Magazine* is a short account of the history of the College, which was first opened on July 1, 1880, fifty years ago, and in which to-day all midshipmen and sub-lieutenants for the engineering branch of the Royal Navy receive their training. For a long time the training of 'engineer boys' and 'engineer students' for the navy was much on the same lines as that of dockyard apprentices, but owing to the recommendations of the Cooper Key Committee of 1875, H.M.S. *Marlborough* was allocated for a training school at Portsmouth in 1878, and two years later Keyham College came into existence. For some time the two establishments ran side by side, but from 1888 onwards all engineering education has been carried out at Keyham. The valuable character of the training given in the *Marlborough* and at Keyham was fully demonstrated during the War, out of which the engineering branch came with a fine record. Nearly all the senior engineer officers in the fleet and at the Admiralty and dockyards had passed through one or the other, in which there has always been a sound combination of instruction in both theory and practice. With the reorganisation of naval education by Lord Selborne and Lord Fisher, entries to Keyham ceased in 1905, and since then the College has seen many changes. Eight years ago, however, all midshipmen for engineering duties were sent there, and to-day there are some 180 midshipmen and sub-lieutenants in residence. As in former days, the instruction is given partly by naval engineers and partly by civilian instructors, and to these have been added a number of naval instructors. The course extends over four years, and the College is fully maintaining and adding to the prestige it enjoyed under the old regime.

"L'AFFAIRE GLOZEL" slowly draws to an inevitable but undignified conclusion. By the irony of circumstance the solution is reached not by the reasoned arguments of the scientific archæologist, but by the empirical methods of the police bureau. The libel action brought by the Fradins, father and son, against those who had impugned the authenticity of the finds they had 'discovered' and exploited, it was obvious, would leave the main issue untouched, and might even have strengthened their position, already well established with the general public. It therefore seemed to the opponents of Glozel that the most effective counter was the institution of a criminal prosecution by the Société préhistorique de France on a charge of obtaining money from the public by exhibiting modern objects as antiques. The exhibits were seized by public authority and examined by M. Bayle of the Service d'Identité judiciaire. This officer found evidence of modern fabrication and affirmed *inter alia* that the bricks had not even been baked and contained substances of modern origin such as strands of cotton coloured by aniline dye, and pieces of moss and grass still retaining chlorophyll, etc. The assassination of M. Bayle has delayed the presentation of the report, which, however, is imminent and will, it is anticipated, be followed by the punishment of the culprit. The whole story is set forth with no little humour and some pungent comments on certain individuals in *Antiquity* for June by M. Vayson de Pradennes, whose intervention in the controversy in 1927, it will be remembered, was crucial. His article is an instructive document, not merely as a detailed survey of the course of events in the Glozel fraud, but in its bearing upon certain aspects of the forgery of antiquities in general.

ALTHOUGH the topical character of the article on Glozel and its bearing upon a sensational series of events gives this feature of the June number of *Antiquity* a special attraction at the moment, the remaining contributions do not fall below it in their level of interest. Prof. Eilert Ekwall writes on the early names of Britain with no suggestion, however, that as yet any name earlier than of Celtic origin is known. Mr. Estyn Evans carries further the investigation of the invasion of Britain at the later stage of the Bronze age by a wave of Celtic-speaking peoples, of which a suggestion was first put forward by Mr. Crawford. He here examines the origin and distribution of certain type specimens of late Bronze age cultures. Dr. Cecil Curwen follows up an earlier communication on prehistoric agriculture by a paper on flint sickles, in which he discusses the interesting problem of the polish on the cutting edge of the flint teeth. The earthworks on Butser Hill, near Petersfield in Hampshire, are discussed at some length with the assistance of air photographs by Mr. Stuart Piggott, who argues that the earliest settlement is to be dated at about 2000 B.C. "Notes and News", from various contributors, include a note by Mr. M. C. Burkitt on a polished stone axe associated with kitchen-midden material from South Africa. He points out that very few polished axes have been found in South Africa, and that this is the first time an association with a definite culture has been demonstrated. He also directs attention to the discovery by Prof. Drennan of a skull and femur of Australoid type in a sand quarry at Cape Flats, near Cape Town.

M. ALBERT THOMAS, in his report as Director of the International Labour Office, refers to the relations between the Soviet Union and the international institutions of the League of Nations. Before 1929 there appeared to be a possibility of definite collaboration in

scientific investigation, but in that year a decided change took place. An offensive against 'bourgeois science' has been developed in Russia, which has taken various forms. Scientific institutions have been reorganised on Marxian lines or have been abolished. Non-communist specialists and technicians have been deprived of their posts, and numerous congresses have been organised to frame new sciences based on Marxian principles. M. Thomas comments that collaboration has been rejected even in the scientific field between Soviet institutions and the international institutions of the 'bourgeois and capitalist' countries, because this would involve the separation of science from politics and a distinction between the examination of the actual situation and Marxian analysis.

AT the meeting of the Royal Statistical Society on June 17, the retiring president, Mr. A. W. Flux, delivered an address on a comparison between the food supply of the United Kingdom in the five years ending 1928 and in the five years ending 1913. For the earlier period, the results of the investigations of the Food (War) Committee of the Royal Society were available, and for purposes of comparison Mr. Flux applied a similar procedure to the five years ending 1928. The examination of the results of the two sets of data showed that no large change in the effective supply of food has occurred, having regard to the numbers for whose maintenance the supplies sufficed. The number of persons whose food supplies were the subject of the two inquiries was substantially the same at the two dates, but the different age constitution of these numerically equal populations renders the needs of the post-War population greater than those of the pre-War population. The 45¼ million of the pre-War population was computed to be the effective equivalent of 35 million adult men, while the equal post-War population was computed to be equivalent to 36 million adult men. The available supplies of food reduced to their energy equivalent gave 4000 calories per day per equivalent adult man. In the make-up of the food, fat had a somewhat larger importance in the later period than in the earlier, while proteins and carbohydrates had a somewhat smaller importance. Dairy produce and vegetables, and, still more, fruit, showed important increases, while meat and cereals both decreased, the latter in greater proportion than the former. In the later period the energy value of the food was derived in the proportion of forty per cent from home produce and sixty per cent from imported produce.

THE British Polar Exhibition will be open at the Central Hall, Westminster, from July 2 to July 15. The exhibition, which is under the patronage of H.R.H. the Prince of Wales, is designed to illustrate the achievements of British polar explorers, especially those of recent times. Numerous exhibits have been lent by museums, learned societies, and private collectors. Among expeditions that will be represented are those of *Erebus* and *Terror*, *Alert*, and *Discovery* to the north, and *Southern Cross*, *Discovery*, *Scotia*, *Nimrod*, and *Aurora* to the south. One section will be devoted to relics, ship models, flags, paintings, and photographs, another to modern work with apparatus and specimens, and a third will be occupied by firms supplying polar equipment. A lecture on north polar exploration will be given on July 2, and one on south polar exploration on July 10. The Scott film recently acquired for the nation has been lent by the trustees and will be shown most evenings and two afternoons. An authoritative polar handbook, with short articles on discovery, meteorology, geology, whaling, birds, diet, etc., and illustrated by maps, will be on sale. A number of recent books on polar work will also be on sale. The organisers are giving their services voluntarily. If, after costs are met, there is any surplus revenue, it will be given to institutes or societies engaged in geographical research.

THE report of about 150 newspaper representatives from various countries upon the sixth *Achema*, or Great International Exhibition of chemical apparatus, at Frankfurt-on-Main, indicates the striking progress which has been made in developing commercial international relationships since the first exhibition of its kind was held ten years ago in Hannover. The press delegates were addressed by Dr. Bretschneider, the organiser of the exhibition, who explained that the primary object of the *Achema* was to promote co-operation between chemists and engineers. The exhibitors this year include many foreign firms, and a prominent feature of this exhibition is the historical section, which includes a model of Liebig's laboratory at Giessen in 1842 and a selection of manuscripts and books. In one section many optical and electrical measuring instruments are displayed and automatic devices for the analysis of gases and liquids, balances designed to record the weight of a dust particle, ultra-microscopes for the detection of molecular movements, and X-ray apparatus for the resolution of crystal structure. An attempt is made to demonstrate in striking fashion the great economies which can be effected by the adoption of standard sizes for the component parts of chemical apparatus. Another section is devoted to the artificial silk industry, the various machines used in all stages of its manufacture being displayed. In the other sections may be seen acid-proof blowers of earthenware, condensing plant constructed of fused quartz, a material which until fairly recently was only used on the small scale, fire-proof building materials, rustless steel, and huge containers constructed of aluminium, nickel, and other metals. The press regards the exhibition as an event of outstanding international importance, since it brings out the vast significance of the present state of development of chemical industry, which plays a leading part in modern civilisation.

ALL workers in scientific and technical fields will welcome the new scheme initiated by the Council of the Association of Special Libraries and Information Bureaux (26 Bedford Square, W.C.1) to form a panel of expert translators. The scheme will be doubly welcome by reason of the undertaking that the members of the panel will consist only of individuals or associations who have satisfied the Council as to their abilities, not merely to translate literally, but also to

interpret the finer shades of differentiation in scientific and technical terminology The difficulty of obtaining such experts has long been recognised Faced by a sudden emergency necessitating expert translation, the would be employer has generally been compelled to rely on the commercial translating bureaux, which are rarely provided with quite the right type of expert required, or alternatively has placed the work in the hands of an individual qualified in the subject concerned but not up to the standard in the particular language involved It is scarcely conceivable, however, that exactly the right type for each particular problem does not exist, and the only requirement for bringing the work and the worker together would appear to be an organisation on the lines proposed by A S L I B This Association has done much towards rationalising the bibliographical realm, and this latest of its activities will meet an urgent and growing need

By the co-operation of the British Post Office Telephones, the Canadian Marconi Company, and the Bell Telephone Company of Canada, Sir Ernest Rutherford, speaking from his home in Cambridge, was able to address the meeting of the Royal Society of Canada in Moyse Hall, McGill University Montreal, on May 20 According to the *Montreal Gazette* for May 21, he congratulated the Society on the efficient manner in which it had encouraged the advance of learning in the Dominion since its foundation in 1882, and its president, Dr A S Eve, on his conspicuous services to McGill University for which Sir Ernest expressed his warm feeling The reception by loud speaker was extremely powerful, in the early stages somewhat blurred but quite clear later Sir Arthur Currie jokingly remarked to Sir Ernest that many of his old students present expected that his voice would be more mellowed by age and honours, while Sir Ernest repudiated Sir Arthur's suggestion that he had not replied to his last letter

During the present week, June 21-28, the North East Coast Institution of Engineers and Shipbuilders and the Institution of Engineers and Shipbuilders in Scotland have been holding their joint summer meeting in Holland, the programme including visits to some of the most important slipyards at Flushing, Amsterdam, and Rotterdam One of these is the Fijenoord Company, which has been in existence since 1823, and which recently completed the motor ship *Baloeran* of 16,000 tons, this being the largest passenger vessel ever built at Rotterdam Nearly as old as the Fijenoord Company is the Werkspoor Company of Amsterdam, a firm which in 1910 constructed the first reversible marine Diesel engine, and which up to the present time has constructed Werkspoor Diesel engines of a total of 365,400 I H P The firm has also recently supplied large screw pumps for the Medemblik and Den Oever pumping stations on the Zuyder Zee Reclamation Works These works, a visit to which was included in the programme, were described by Mr J W. Thierry in a paper to the British Association in 1928, and in *Engineering* for May 23 and June 30 and succeeding issues he is giving further particulars of these important undertakings, which will ultimately add more than half a million acres of land to Holland Among other places visited was the Nautical Technical Institution and Museum at Rotterdam, founded in 1916 by private subscription for furthering the interests of shipbuilding and nautical science, but which is open to the public

For the latter part of the meeting, the headquarters of the Institutions was at Scheveningen, a seaside town on the coast, off which took place the action between the English under Monk and the Dutch under Tromp when the latter was killed Here on June 25, two papers were read, one on the " Interior Architecture of Ships " by Prof P A Hillhouse and Mr A M Gardner, and the other on " Transportation of Oil by Sea ", by Mr J McGovern, the President elect of the North East Coast Institution The world production of petroleum, said Mr McGovern, had increased from 70,000 tons in 1860 to 213 million tons in 1929, while the present fleet of oil tankers had a carrying capacity of approximately ten million tons, the ships forming about 11 per cent of the total world tonnage Though oil at first was carried either in barrels or in wooden ships especially altered for the purpose, the prototype of the modern oil tanker was the *Gluckauf*, built by Messrs Armstrong in 1885. In this ship boiler riveting was adopted throughout But the general design of oil carrying vessels followed that of the ordinary cargo ship until Sir Joseph Isherwood introduced the longitudinal system of framing, which resulted in increased longitudinal strength with a reduction in the weight of material His patent was taken out in 1906, the *Paul Paix* was built on this system in 1908, and was the forerunner of the 943 oil tank vessels built or ordered according to the Isherwood plans In recent years, owing to the carriage of benzine, or oil containing sulphur or acids, corrosion has increased, and unless the metallurgist or chemist can produce more suitable steel or protective coating it would appear that the life of some tankers would be limited to ten or fifteen years

The annual report and accounts for 1929 of the Ross Institute and Hospital for Tropical Diseases, Putney Heath, London, S W 15, has been issued The work of the Institute is reviewed, including research work and malaria expeditions The total receipts from donations and subscriptions show an increase of £2500, and income over expenditure a surplus of £2467, but as the Institute has no endowment fund, the balance of £12,000 in hand must be regarded as a reserve against contingencies

A useful little catalogue (No 12) of second hand books of botanical interest, including some rare herbals, has been issued by Mr J H Knowles, 92 Solon Road, S W 2

Applications are invited for the following appointments, on or before the dates mentioned —A full time graduate science assistant master at the Hammersmith School of Building and Arts and Crafts—The Education Officer (T 1), County Hall, S E 1 (June 30). A senior mathematical master at Swin

don College—The Principal, The College, Swindon, Wilts (July 1) Assistant lecturers in chemistry, physics, botany, and pharmacy at Cardiff Technical College—The Principal, Technical College, Cardiff (July 2) An assistant for metalwork and mechanical drawing at Darlington Technical College—The Chief Education Officer, Education Office, Darlington (July 4) A lecturer in physics and electrical engineering at Handsworth Technical College—The Principal, Handsworth Technical College, Handsworth, Birmingham (July 4) Civilian education officers in the R A F educational service, one with a degree in engineering and one with a degree in history—The Secretary, Air Ministry, Gwydyr House, Whitehall, S W 1 (July 5) A full time teacher in engineering, a full-time teacher in physics, and a visiting teacher for engineering economics, at the West Ham Municipal College — The Principal, Municipal College, Romford Road, West Ham, E 15 (July 5) An honours graduate to teach pure and applied mathematics at Loughborough College—The Registrar, Loughborough College, Leicestershire (July 5) An assistant lecturer in education with special qualifications in the teaching of science subjects at the University College of the South west of England—The Registrar, University College, Exeter (July 7) A technical assistant to the adviser in agricultural economics at Armstrong College — The Registrar, Armstrong College, Newcastle upon Tyne (July 7) Geologists on the Geological Survey of Great Britain —The Director, Geological Survey and Museum, 28 Jermyn Street, S W 1 (July 9) An assistant lecturer in economics in the University of Birmingham—The Registrar, The University, Edgbaston, Birmingham (July 11) A lecturer of botany at the University College of Wales, Aberystwyth—The Financial Secretary, University College of Wales, Aberystwyth (July 14) A demonstrator in mathematics at the Royal College of Science, South Kensington—The Secretary, Imperial College of Science, South Kensington, S W 7 (July 14) An assistant lecturer in zoology in the University of Bristol—The Secretary, The University, Bristol (July 14) An additional lecturer in engineering at Chesterfield Technical College—The Principal, Chesterfield Technical College, Chesterfield (July 15) Two botanists for cacao research at the Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 14 Trinity Square, E C 3 (Aug 19) A professor of hygiene in the Egyptian University, Cairo, and a lecturer in dental surgery—The Dean of the Faculty of Medicine, Egyptian University, Cairo (Sept 20) A headmaster of Christ's Hospital, Horsham—The Clerk, Christ's Hospital, 26 Great Tower Street, E C 3 A whole time lecturer in geography at St Mary's College, Strawberry Hill—The Principal, St Mary's College, Strawberry Hill, Middlesex Instructors in electrical engineering, advanced building construction, and practical mathematics at the Kingston upon Thames Technical College and School of Art—The Principal, Technical College, Kingston upon Thames A full time assistant master for engineering at Erith Technical College — The Principal, Erith Technical College, Belvedere, Kent Inspectors for the purposes of the Diseases of Animals Act, 1894–1925, under the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 A professor of natural philosophy in the University of Aberdeen—The Secretary, The University, Aberdeen

Our Astronomical Column

Remarkable Meteors —Mr W F Denning writes that on June 9, at about $0^h\ 35^m$ A M G M T, a large fireball was seen from many places in the north of England It presented a white nucleus which looked nearly as large as the full moon and lit up the country About twelve observations have been received, from which it appears that the fireball was directed from the N N W sky and was probably at a height from 60 to 50 miles The radiant was not far from the horizon, but the data are somewhat conflicting and exact deductions are scarcely possible

Fireball of June 15 —At $23^h\ 12^m$ P M G M T a meteor equal Venus was observed by Mr Kingman at Bristol It passed from 261° + 21° to 305° + 59° and was directed from a radiant in Scorpio near 237° – 25°

An Early Perseid.—On June 15 at $23^h\ 22^m$ G M T a first magnitude meteor with the very swift motion and bright streak characteristic of the Perseids was well observed It shot from 359° + 75° to 142° + 74° and its direction conformed very nearly with the radiant point of the Perseids on the same night which is in the region dividing Pegasus and Lacerta at 342° + 3[illegible]

On June 16 at 1 30 A M G M T, when scarcely any stars were distinguishable in the misty sky, a fine meteor was noticed from Bristol as it ascended from the horizon in due west and sailing upwards disappeared when nearly reaching the zenith—velocity slow, duration 10 seconds

Further accounts of these curious objects will be valuable for computing the real paths

Occultations of Stars by the Moon —The April issue of the *Journal* of the Royal Astronomical Society of Canada contains an article on this subject by Prof E W Brown He notes that the campaign of observations of occultations which is now being vigorously carried on in many countries, dates from a paper by Dr R T A Innes (1923), in which he showed the value of such observations for determining the errors of the lunar tables Prof Brown considers that since the introduction of the new lunar tables in 1923, the chief residual errors in the moon's position are due to irregularities in the earth's rotation He gives two diagrams of the moon's residuals, one on a small scale from 1650 to 1930, the other on a larger scale from 1875 to 1928 In forming these he has omitted from his tabular places the "great empirical term" with period of about 2½ centuries, as he considers that the cause of this, as of the smaller fluctuations, lies in the earth's rotation, not in the moon A feature of the graphs is the abruptness of the sudden changes of direction The dates of the more marked changes are 1780, 1898, 1917 Prof Brown notes that these observations are eminently suited for amateurs A 3 inch telescope suffices, and a clock or watch sufficiently good to give to the nearest second the interval between a wireless time-signal and the phenomenon

Research Items

Harvard-Boston Expedition's Excavations in the Sudan—In *Sudan Notes and Records*, vol 12, pt 2, Dr G A Reisner reports on the excavations which were carried out in the seasons 1927–28 and 1928–29 at the forts at Semna and Uronarti as part of a larger plan to examine all the old forts extending from Semna to Halfa It is known that these forts of Semna and Uronarti were built before or during the twelfth dynasty, when trade, which in earlier times had suffered much from hostile tribes, had become organised and the country subdued by military expeditions The northern Sudan was then occupied by officials who were little more than trading agents, transport was maintained mainly by water, and protected by fortified posts along the river The desert tribes were a constant source of danger to the trading fleets The excavations have served to throw light on the methods of navigation of the cataract and how traffic was controlled by land and water The ramparts of the forts command a wide view, and signalling from fort to fort was possible They completely dominate both land and water routes Each was built on a hill and the plan was drawn to suit the configuration Inside the thick outer wall of crude brick ran a street and the space inside the street was divided into blocks by cross streets Each block was divided by walls into separate apartments, providing temples, dwellings for the commandant and officers, barracks for the men, storehouses, etc Judging from the quarters and the cemeteries, in which the burials include women and children as well as men, the garrisons must have been small, perhaps from 50 to 150 fighting strength The forts were all occupied in the New Kingdom, and later, many of the important objects discovered belonging to this period

Inheritance in Man—The Galton Lecture before the Eugenics Society is published in the *Eugenics Review* (vol 22, No 1) In it Prof S J Holmes discusses natural selection in man, and reaches the general conclusion that under modern conditions selection is more effective in eliminating the less endowed than is usually supposed He gives reasons for thinking that the intelligence quotient is, on the average, the most important single factor in survival, and that "the present economic order is much more deadly to people with dull minds" The death rate tends to be high in proportion as the occupation requires little intelligence or skill On the other hand, selection against many physical defects has been largely eliminated Racial differences in susceptibility to disease exist For example, negroes have a low death rate, as compared with whites, from scarlet fever, erysipelas, diphtheria, measles, and skin diseases, but a high mortality from tuberculosis, pneumonia, and other respiratory diseases From statistics of mortality rates, Prof Holmes reaches the conclusion that the male is inherently the weaker sex, although a part of the higher male infant mortality is due to recessive sex linked factors and a part to birth trauma He finds that the male death-rate during the first year is high owing to faults of organisation, and that the male death ratio from epidemic diseases is also high during this period

Measurement of Ultra-Violet Radiation—The simple method of measuring the biologically active ultra-violet rays of the sun introduced by A Webster and Leonard Hill, and now used at many meterological stations, consists in the fading of a standard solution of acetone and methylene blue in a quartz tube The degrees of fading are tested against a set of standard colour tubes, and each degree represents two to four times the dose of ultra-violet rays required to produce erythema of the white skin—two to four because skins vary in sensitivity The standard solution exposed to the sunlight in the presence of air fades somewhat in a tube of glass which excludes the biologically active ultra violet rays There is, however, very little fading when air is excluded, and any error due to fading by long waved ultra-violet and visible rays can be excluded by exposing a control sample of the standard solution in a glass tube, and deducting the degree of fading of that from the degree of fading in a quartz tube Dr M Bender, of the Institut fur Strahlonforschung, Berlin, informs us that he has introduced a variation of method, namely, exposing a solution of acetone and determining the action of the ultra violet rays on this by adding a standard solution of Fuchsin Schwehlige Säure and determining the depth of red violet tint produced He claims that this modification gives good agreement with cadmium cell determinations of the ultra violet rays A detailed account of his results will be published in *Strahlentherapie*

Life History of the Pismo Clam—Mr William C Herrington gives an interesting account of the bionomics of *Tivela stultorum* (Mawe) with special reference to its depletion ("The Pismo Clam, Further Studies of its Life History and Depletion" Division of Fish and Game of California *Fish Bulletin*, No 18 Contribution No 81 from the California State Fisheries Laboratory) This huge heavy shelled bivalve at eight years old may weigh from one to four pounds It is found in abundance on the open sandy beaches of California, but only where it is exposed to constant washing and pounding of the surf extending from the intertidal zone out into the surf for an unknown distance and in places forming a successful commercial fishing Prof F W Weymouth ("Tho Life History and Growth of the Pismo Clam", 1923, No 7 of this publication) has already described fully its habits and appearance The present paper is specially concerned with the extent and cause of depletion, effect of present protective methods, relation of dominant year classes to fluctuations in abundance, age at sexual maturity, relation between size and number of eggs, growth rate and deviation from the normal in the growth of individual year classes Spawning begins at the end of the second or third year The eggs are very small and the average number in specimens from seven to ten years old is 75,000,000 per clam, the smallest producing the fewest eggs The growth shows a distinct seasonal rhythm, rapid in summer and slow in winter The large clams have been steadily dwindling in numbers in spite of the bag limit and the size limit The growth rate does not appear to be affected by crowded conditions There are great fluctuations in abundance, due principally to dominant year classes and the effects of the fishing The greatest fall is in the tidal zone, especially in the Pismo Oceano Beach, where so many visitors dig for clams and are the probable cause of the scarcity Stricter protection of undersized clams is advised and regulations which will decrease the strain on the breeding stock, if the Pismo clam fishery is to be maintained

Chondrocranium of the Lizard—The morphology of the chondrocranium of *Lacerta agilis* is known to most students of zoölogy from the reconstructions of Gaupp of 31 mm and 47 mm stages De Beer (*Quart. Jour Micro Sci*, May 1930) has described

the detailed development of the chondrocranium from the first cartilage to appear, namely, Meckel's cartilage, up to nearly the younger of Gaupp's stages The employment of van Wihje's victoria blue staining technique enables the cartilage to be differentiated from the pro cartilage and so makes the identification of the former more accurate than was possible by older methods From his observations the author concludes that in all living reptiles, excluding Ophidia which are highly specialised, there is the same general form of a tropitrabic skull, with a trabecula communis, an interorbital septum, and a planum supreseptale, and in all the posterior portion of the orbital cartilage is more or less reduced *Lacerta* has certain affinities with such Chelonia as *Emys*, *Chrysemys*, and *Chelydra* In addition, the lacertilian chondrocranium has several points of similarity with that of *Sphenodon* and the crocodiles or, in other words, the Diapsida, which may be taken as suggesting that the Lacertilia have been derived from this group

Colour Change in Fishes —Mr Charles Haskins Townsend, director of the New York Aquarium, has published a very interesting booklet entitled "Records of Changes in Colour among Fishes" (New York Zoological Society, 1929) Besides copious notes made from the fishes in the aquarium, there are many beautiful illustrations, both photographs and coloured drawings The coloured plates are specially good, particularly those by Hashine Murayama, whose sketches are wonderfully alive The colour changes are usually instantaneous, as many as seven quite different guises being observed Some of the changes are due to uncomfortable surroundings or sickness, but most of them are adaptations to surroundings; sometimes a colour change may be attributed to anger or fear The author has in previous works emphasised the fact that one colour description or drawing is not sufficient to identify a fish The present work fully bears out this statement

Larvæ of the Coleoptera —In the *Bulletin of Entomological Research* for March 1930, pp 57 72, will be found a useful paper by Mr A W Rymer Roberts, consisting of a key to the larvæ of all the chief families of the Coleoptera It is now more than twenty six years since MacGillivray's paper on the same subject appeared and, in the interval, a large amount of exact knowledge of the larvæ of various genera and families has come to light The foremost modern worker in this field, Dr Adam G Böving, has published a large amount of high class research, and the results of his work, and those of other entomologists, have been freely drawn upon by Mr Roberts in order to make his paper as complete as possible It is obviously beyond achievement at present to provide a complete key of this kind because, in a few families, the larvæ are still unknown or too poorly described for inclusion These necessary omissions, however, are so few that their effect on the value of Mr Roberts's paper is almost negligible Users of his tables will find the terminology adopted relatively simple, and there is, further more, an illustrated glossary of the terms employed At the end of the paper the reader will find a guide to the more important literature on the subject up to and including the year 1929 The general classification followed is that used by Reitter in the "Fauna Germanica", which is a readily accessible work

Microscopic Examination of Coal —Under this title Mr Clarence A Seyler gives a very clear, straightforward account of methods of preparing microscopic sections of coal or of preparing polished, etched surfaces for examination in reflected light It is published as No 16 of the Physical and Chemical Survey of the National Coal Resources, by the Fuel Research Division of the Department of Scientific and Industrial Research (London H M S O) Mr Seyler states that the tissues which are met with still in a more or less intact form in coal are either secondary xylem or periderm, usually fibrous tissue with the cells considerably elongated in the axial direction Usually the pieces lie in the coal in a horizontal direction, so that the plant axis lies parallel to the bedding plane. A full description is given of the methods by which the investigator can elucidate the plant structure by sections in directions transverse, radial longitudinal, and tangential longitudinal to the plant axis No other method of preparation of material for microscopic examination is dealt with other than that of sections Possibly, the new methods, using collodion or gelatine films, are not readily applicable to this material, but it would seem probable, especially where plant spores are the main recognisable material in the coal, that maceration methods would give results of value

Chromosomes of *Prunus* —In the genus *Prunus* the *n* number of chromosomes is 8 Dr Darlington (*Jour of Genetics*, vol 22, No 1) has made a further study of the cytology of this genus, in which he finds that the various forms of plums and damsons examined were all hexaploid In meiosis they usually form bivalent chromosomes, but occasional quadrivalents occur The wild *P spinosa* is tetraploid and also forms occasional quadrivalents It was found that in the hybrids of *P domestica* ($6n$), *P cerasifera* ($2n$), *P triflora* ($2n$), *P persica* ($2n$), and *P Amygdalus* ($2n$), there is perfect chromosome pairing in meiosis, which is taken to indicate that the chromosomes in the haploid sets of these species are homologous each to each *P domestica* × *cerasifera* produces a tetraploid form which behaves like a true species, all the chromosomes pairing, but certain of the pairs also uniting to form quadrivalents Various abnormalities of meiosis in these hybrids are also described, and classified under four heads, including omission of one or both meiotic divisions, the division of binucleate pollen mother cells, and the double division of the chromosomes when they have failed to pair From such conditions, *P avium nana* having 24 chromosomes in its sporophyte may produce gametophytic nuclei with 96 chromosomes It is pointed out that from the pairing of chromosomes conclusions regarding their relationship cannot always be drawn, and a relation between pairing and chiasma formation is suggested

Terrestrial Magnetic Surveys —The "Results of the Magnetic Observations made by the Ordnance Survey in England and Wales in 1928" (London H M S O, 1s net) gives complete data for *D* (declination), *I* (inclination), and *H* (horizontal force) for 30 stations, reduced to the epoch 1929 5, six of these stations were repeat stations, and for these the secular variation is given Preliminary declination results are given also for seventeen stations observed in 1929, fifteen being in the Scottish Lowlands, and two in the magnetically disturbed region near Melton Mowbray, three of the seventeen are repeat stations The instruments used for *D* and *H* are a coil magnetometer designed by Dr F E Smith, for *I* a dip circle is still used The Swedish Hydrographic Service have issued a *Magnetic General Chart of Sweden*, 1930 (Jordmagnetiska Publ Nr 7, Stockholm), giving, on three separate maps, isomagnetic lines for *D*, *I*, and *H* The observations on which the maps are mainly based were made with a Carnegie Institution pattern of combined magnetometer and earth inductor, the field work being done in 1928 and 1929, the stations chosen are to be repeat stations, at each

of them, the local variation of vertical intensity is tested by a variometer of the Ad Schmidt pattern

Physics in Fuel Research—In November last, Dr C H Lander, Director of Fuel Research, addressed the Institute of Physics on "Physics in Relation to the Utilisation of Fuel" and this lecture has just been published by the Institute Perusal of the reprint confirms the view that one can scarcely take a step in this, as in any industry, without involving some physical principle or process They are here indicated at all stages from the mine to the chimney stack To cite a modern example, it has been found that X rays prove useful in investigating and controlling the cleaning of coal, while X ray spectrometry is assisting in distinguishing the different forms of carbon in coke, which influence its reactivity All processes of coal cleaning utilise differences in the physical properties of coal and dirt The utilisation of fuel is obviously 'applied heat' The combustion of solid fuel is essentially a problem of air supply, and especially with pulverised fuels it is a question of controlling the relative motion of a gas over a solid Heat transfer involves the laws of radiation, conduction, and convection The conditions in practice are usually baffling in complexity, but the application of physical methods of study is carrying us further than the empirical methods of the past

Band Spectrum of Chlorine—An investigation of the absorption bands of chlorine, described by A Elliott in the June issue of the *Proceedings of the Royal Society*, is of interest in connexion with the nuclear properties of this element Four bands assigned to the molecule $Cl^{35}Cl^{35}$, and two assigned to $Cl^{37}Cl^{35}$ have been analysed, and it has been found, by means of intensity measurements, that the nuclear spin of the atom Cl^{35} is 5/2 quantum units, and that the lighter molecule is about 1 45 times as abundant as the heavier The latter number is decidedly less than the value 1 67 calculated from the direct measurements of the isotope ratio made by Dr F W Aston, but whilst the discrepancy is possibly due to errors in the spectroscopic work, it is apparently not quite certain that it is not real, and due to a greater absorption per molecule by the system $Cl^{37}Cl^{35}$ than by $Cl^{35}Cl^{35}$

Failure of Insulators due to Deposition of Sea Salt—A new instrument called a 'klydonograph', which has been much used in the United States for the recording of lightning flashes and atmospheric phenomena, has been found specially useful in connexion with overhead electric lines It is very important to know the causes of the sudden surges of electricity which cause breakdowns in high pressure electric supply systems The principle of the instrument is based primarily on the phenomenon known as Lichtenberg's figures Under electric stress, particles of certain kinds of powder, particularly sulphur, arrange themselves in a definite manner in the electric field Later on, it was discovered that the emulsion of a photographic plate was affected in a similar way by electric stress A voltage of 2000 across the electrodes is sufficient to give a record and by having a moving film a continuous record can be obtained In a paper read by S W Melsom, A N Arman, and W Bibby to the Institution of Electrical Engineers on April 10, interesting surge investigations on a 33 kilovolt line in South Wales which supplied a number of collieries and villages were made They traced breakdowns to a salt deposit which occurred on the insulators of the line following dry south westerly winds. The line was about twenty miles from the coast With a dry wind the salt spray is taken up, dried in the air and carried for considerable distances as a fine powder The salt powder impinges on the insulators and, helped by the electric stress, adheres firmly to them So long as the dry wind continues there is little danger of a flash over, but when the humidity of the air becomes normal the insulator gets covered with brine, which is a good electric conductor and leads to dangerous surges on the mains It was instructive to find that the greater part of the surging occurred on that one of the three phase conductors which was nearest the sea

Electric Currents to the Ground—A fresh estimate of the relative importance of the various agencies concerned in the transport of electricity between the ground and the air has been made by Dr T W Wormell in the June number of the *Proceedings of the Royal Society* (pp 585 589) The agents considered were four, the normal fine weather current and precipitation, which cause on the whole a downward movement of positive electricity, and lightning discharges and currents from points, the effect of which is in the opposite sense The numbers given for the charges brought to the ground by these in a year (with special reference to conditions near the Solar Physics Observatory at Cambridge) are respectively +60, +20, −20, and −100 coulombs per square kilometre These values are necessarily only approximate, but it seems very probable that the current carried by lightning and the point discharges together exceeds considerably the current carried down by rain, which is in the opposite direction, so that there is effectively a vertical upward current through a cumulo nimbus cloud from the earth to the upper atmosphere Dr Wormell refers to two other investigations which confirm this result, and remarks that they are in entire agreement with the theory of Prof C T R Wilson that the fine weather current into the ground over the whole earth is balanced by the currents maintained between the earth and the upper atmosphere by shower clouds

Recombination of Atomic Hydrogen—A preliminary report of some remarkable results obtained in connexion with the recombination of hydrogen atoms to form molecules has been published by F J Havlíček in *Die Naturwissenschaften* for May 30 The reaction was studied in gas at atmospheric pressure, and it was found that the concentration of atomic hydrogen fell off exponentially with time The time taken for the concentration to fall to a definite fraction of its initial value being thus independent of the initial concentration, it was concluded that the reaction was *mono molecular*, a result checked by the law governing the dependence of the decay constant upon temperature in the range between about 50° C and 500° C Details of the experiments are not given, but must be awaited with the greatest interest, as it is somewhat difficult to reconcile these facts, if substantiated, with the ordinary ideas of recombination taking place as the direct result of collisions

Analysis of Silicates—We have received from the Society of Glass Technology, Darnall Road, Sheffield, a copy of a brochure entitled "The Analysis of Glasses, Refractory Materials, and Silicate Slags" just published by the Society It contains eight papers or abstracts, some having been read to the Society during 1927 and 1928, with the discussions, and in one case the paper has been modified in the light of later investigations There is also an index The details given are sufficient for the guidance of any competent chemist, and the critical comments provide a review of the limitations and difficulties of the methods described The book, which is edited by Prof. W E S Turner, is a useful contribution to the analytical chemistry of silicates

Physics and Chemistry in the "Encyclopædia Britannica".

PHYSICS

THE editors claim that the physics programme is one of the most comprehensive and authoritative of the different divisions of the "Encyclopædia Britannica" Anyone wishing to use the work in the study of this branch of knowledge, after reading the article "Science", which surveys the whole world of scientific achievement, would be well advised to refer to "Physics, Articles on", for the main subdivisions and separate headings Sir Oliver Lodge, in the main article "Physics", discusses the history and development of the science which, by its derivation, means a study of Nature so far as it can be reduced by calculation and experiment to a few simple, or at least fundamental, laws It was hoped at one time that the mechanical laws of Galileo and Newton would be all inclusive Efforts to apply them not only to matter but also to the ether, and even to life and mind, and thus to find a basis for a materialistic philosophy, have proved unsuccessful So long as we are dealing with massive bodies or with great groups of particles, the Newtonian laws of dynamics are sufficient, and they reigned supreme till very near the end of the nineteenth century Modern physics may perhaps be said to date from 1895, the year of Röntgen's discovery of X rays This discovery not only provided the physicist with a new tool, it illustrated the idea put forward by Lorentz and Zeeman, and also by Larmor, that electric charges were the agents responsible for the generation of radiation

Prof Millikan, who writes on the "Electron" with authority, insists that one of the most important generalisations of all time is that of the electrical constitution of matter, for this conception underlies practically the whole of twentieth century physics The growth of this idea was gradual, and illustrates the fact that, for the most part, the progress of science takes place by a process of infinitesimal accretion In 1891, Johnston Stoney introduced the word 'electron' to designate a definite elementary quantity of electricity demanded by Faraday's laws of electrolysis—"Finally nature presents us with a single definite quantity of electricity which is independent of the particular bodies acted on" Stoney implies that every atom must contain at least two electrons, one positive and one negative, because otherwise it would be impossible for the atom as a whole to be electrically neutral In 1897, J J Thomson showed that the mass of the particles constituting the cathode rays was of the order of a thousandth of the mass of the hydrogen atom Later experiments have shown that the positive electron, while it has a charge of equal amount but opposite sign to the negative, is always associated with a *mass* about 1845 times greater "The positive electron is sometimes called the proton, and the word electron, when used without any qualifying adjective is usually understood to refer to the negative electron, but it is important to remember that historically, derivatively, and logically the word *electron* means, as indicated above, the unit *charge*, and carries no implication as to mass"

The oil drop experiments of Millikan prove that all electrical charges are built up out of a definite number of discrete elements or particles all exactly alike, the value of the electron charge being $e = 4\ 774 \times 10^{-10}$ absolute electrostatic units (the value quoted as "the latest determination" in the article "Physical Units" is quite out of date)

The dissection of the atom into electric charges is discussed by Prof Niels Bohr ("Atom"), who gives an account of his own most important theoretical work on the building up of groups of electrons round a massive positive nucleus to form a neutral and stable system He adds an interesting account of recent progress, dealing with the remarkable developments since 1925 associated with the exact quantitative treatment of the new quantum methods A more detailed account of the "Quantum Theory" is given by Prof W Wilson, who contributes an article of exceptional lucidity His description of the new wave mechanics and matrix mechanics is one of the best summaries with which we are acquainted

The third great advance of the present century, supplementing and consolidating the electron theory and the quantum theory, is the theory of "Relativity" This is treated in his usual able manner by Sir James Jeans, who also writes on the "Kinetic Theory of Matter" The general nature of the principle of relativity is first described "Just as Tycho's eight minutes of arc, in the hands of Kepler and Newton, revolutionised medieval conceptions of the mechanism of the universe, so Leverrier's 43 seconds of arc, in the hands of Einstein, has revolutionised our nineteenth-century conceptions, not only of purely astronomical mechanism, but also of the nature of time and space and of the fundamental ideas of science The history of this revolution is in effect the history of the theory of relativity It falls naturally into three chapters, a first narrating the building of the earlier physical theory of relativity, a second dealing with the extension of that theory to gravitation, and a third, which is still in process of being written, attempting to include electro magnetism in the physical system presented by the existing theory of relativity"

Mr Bertrand Russell discusses the philosophical consequences of relativity, and Prof Einstein gives an important if somewhat difficult account of "Space time", which is followed by a short description by Prof Eddington of recent attempts to absorb the electro magnetic field, and so provide a single background to all material activity—one unified field

A few of the more interesting articles on physics may here be mentioned Prof Andrade, who is the associate editor for physics, contributes articles on the atomic "Nucleus", on "Radiation", "Rays", on "Vacuum" and on "Transmutation of the Elements" Sir Ernest Rutherford writes on "Radioactivity", Sir Joseph Thomson on "Electricity, Conduction of", and on "Electric Waves" Dr Aston is specially qualified to discuss "Positive Rays" and "Isotopes", and Prof A Fowler to write the article on "Spectroscopy" The nature of "X rays" is discussed at length by M de Broglie, and X ray spectroscopy by Prof Manne Siegbahn, both of whom describe work with which they are themselves identified The standard articles on the branches of the older physics are assigned to the late Prof Callendar ("Heat"), Prof C G Darwin ("Light"), Dr A. B Wood ("Sound"), Prof H. A Wilson ("Electricity"), Dr E C Stoner ("Magnetism") Among the articles on the technical applications of physics may be cited an interesting account of the applications of "X rays" by Dr E V Pullin, "Wireless Telegraphy" by Prof Appleton and Dr Eccles, and "Photography" by Mr George Eastman and Dr C. E K Mees

The article on the "Wilson Cloud Chamber" deserves special mention, if only on the ground of the excellent reproductions of photographs of cloud tracks obtained by means of this apparatus. The paths of swift electrified particles are thus rendered visible, and it is possible to study the tracks of α and β particles and of electrons released by the

action of X-rays Of striking value are the photographs showing the expulsion of a proton by the impact of an α particle (Meitner), and the forked tracks showing nuclear collision of an α particle in oxygen and in helium (Blackett)

Science knows no national boundaries, but the policy adopted by the editors of asking foreigners to contribute articles on their own special subject suffers from several disadvantages, even when the author is recognised as one of the most distinguished specialists When reading such an article, it is evident that the writer is often translating his thoughts from his own language into English, so that the mode of construction is essentially foreign, and in some cases the word chosen to represent a technical term is not that best suited for the purpose The latter difficulty might perhaps have been avoided by more careful editorial supervision One could, however, go further and say that it is not merely the difference in language which creates an obstacle, there may also be a difference in the very mode of thinking which raises a barrier between author and reader In an original and independent contribution to science or learning, this is serious enough, but in an encyclopædia it is more than a drawback, it is almost a disqualification

We must not end, however, on a critical note Considered as a whole, these contributions to the study of experimental and mathematical physics reach a very high level, and are bound to have an important influence in the dissemination of accurate knowledge and in stimulating further scientific research

H S A

CHEMISTRY

It will be within the recollection of many of those for whose education encyclopædias are published, that Kai Lung's remote ancestor spent his entire life in crystallising all his knowledge and experience into a few written lines, which as a result became correspondingly precious The sentence "defined in a very original and profound manner several undisputable principles, and was so engagingly subtle in its manner of expression that the most superficial person was irresistibly thrown into a deep inward contemplation upon reading it" What an attractive encyclopædia the old gentleman and his co compressionists could have produced! How immeasurably greater would his achievement have been if his sentence could have changed its shades of meaning and enlarged its philosophical perspective with advancing thought and maturing experience! That, in effect, is what a maker of encyclopædias is called upon to do In a few short years the cut of the garments of a science such as chemistry appears impossible and even unhealthy, and the fabric itself gets moth eaten in places, some of the embroidery, too, now appears superfluous New discoveries are to be recorded, the ensemble has to be viewed afresh, new hopes arise while the epitaph is being written on the old

Presumably the editors of the "Encyclopædia Britannica"—the encyclopædia of the English speaking peoples, as it has been more exactly described —found it possible to revise a proportion of the chemical articles which appeared in the last edition, but it is evident that most of the matter has been entirely re-written Let it be said immediately that by undertaking the onerous and responsible duties of chemical editor, Prof G T Morgan has earned the thanks as well as the congratulations of both the scientific and the general public, so far as the chemical articles are concerned, the selection of the authors, all eminent exponents of their subjects, leaves nothing to be desired. The encyclopædia is not intended to be either a text book for students of chemistry or a reference book for chemists, nevertheless, the authors of the articles on chemical themes are just those to whose views and to whose exposition of them chemists themselves would most willingly pay attention In nearly every case (one cannot truthfully omit the "nearly") they have steered a middle course and appealed to the hypothetical intelligent layman who, with the man in the street and the average man, having been so long and so often the butt of our shafts of learning and wit, must surely now be possessed of a knowledge so encyclopædic as to render him independent of encyclopædias As a working hypothesis it is reasonable to assume that the most renowned specialist is in the view of another and different kind of specialist, just that ignorant but interested reader whose comprehension he must not underrate and whose curiosity he is anxious to arouse Whether such an assumption were made or not, in the result we have that combination of clarity, brevity, and solidity that appeals to the scientific worker

In such a collection of miniature monographs one does not expect uniformity Indeed, chemistry itself is far from uniform in methods in development, in language from exponents of different phases of the science, therefore, similarity of approach, unanimity of appeal, and equality in the assumption of premises are not to be anticipated As the same chemist is not usually deeply interested in both solutions and synthetic dyes, or in both gunpowder and glucosides, so the subject itself is too wide to admit of homogeneity in its revelation to the general public Hence it would not be fair to say that the article on "Thermochemistry" (Mr H T Tizard), for example, is less popular than that on "Valency" (Dr N V Sidgwick), because the former makes sparing use of mathematics, or that "Dyes" is more technical than "Catalysis", because it incorporates a large number of hexagons In point of fact, "Catalysis" (Dr E K Rideal) is a good example of an authoritative article which appears to have been written for the 'brethren', and "Synthetic Dyes" (Mr A G Green) of a highly technical subject treated in such a manner as to make the non chemical reader feel that he has missed his true vocation "Flame" (Prof A Smithells) is accompanied by photographs of types of flame structure, it is restricted to stationary flames Among other articles which deserve to be mentioned in any description of the chemical service of the encyclopædia are such, for example, as Prof G T Morgan's "Diazo Compounds" and "Organo Metallic Compounds", Mr J A V Butler's "Solutions"—pleasant as well as instructive reading—Prof W N Haworth's "Carbohydrates", Dr W H Mills' "Stereochemistry" (a lucid exposition of a difficult subject), Dr T A Henry's "Glucosides" and "Alkaloids", Prof R Robinson's "Chlorophyll", Dr A D Mitchell's "Ammonia", and Dr S E Sheppard's "Photochemistry" One finds notable revisions, such as "Argon" by the late and the present Lord Rayleigh, and "Atomic Weights" by the late Prof T W Richards

A comprehensive general review of the science of chemistry is offered in an article extending over nearly sixty pages and contributed by Prof H B Dixon ("History of Chemistry"), Dr J D Main Smith ("Inorganic Chemistry"), Dr E Holmes ("Organic Chemistry Historical"), Prof F Francis ("Organic Chemistry Aliphatic Division), Prof J. Read ("Organic Chemistry Homocyclic Division"), Mr R H F Manske ("Organic Chemistry, Heterocyclic Division), Prof H M. Dawson ("Physical Chemistry"), Mr B. A Ellis ("Analytical Chemistry

Inorganic)", Dr M A Whiteley ("Ultimate Organic Analysis"), and Mr E W Yeoman ("Gas Analysis") It is a substantial article, and a substantial contribution to the literature of chemistry In a work of such magnitude as the "Encyclopædia", the definition of boundaries must have presented considerable difficulties in seeking to provide for a thorough survey of the borderland between one science and another those regions lying between chemistry and engineering, or between chemistry and economics, for example, have acquired an importance second to none in the industrial outlook, both of the English speaking and of other peoples Due regard has been had to such common issues, but only a careful and exhaustive analysis of the treatment of cognate subjects shared both with other sciences and with other human interests would show whether the impression that little of first importance has been overlooked is accurate Ions, although discussed incidentally, have (except in regard to their catalytic action) scarcely been accorded their usual place of honour in chemical theory, whilst noticeable, this is doubtlessly completely devoid of significance

Allusion to the relation of chemistry to other human interests invites reference to the article entitled "Chemical Warfare", by Brig Gen Sir H B Hartley and Mr C G Douglas, where developments resulting from the use of gas as a military weapon by the German Army are described, together with measures adopted for protection against its effects In view of its efficacy as an arm in the field, the probability of its proving equally potent when used in conjunction with aircraft against industrial centres or even against the civilian population, and the ease with which chemical industry organised for essential national requirements in times of peace can be converted into an arsenal in time of war, the possibility of the future use of military gases in spite of international agreements is one which, we are warned, is felt not to be remote Until the danger is effectively removed by statesmen, it will remain all too obvious to chemists A A E

The Climate of the Pleistocene Period *

THE glaciation of northern Europe during the great Ice Age was due to a shift of the pole associated with appreciable variations of solar radiation

The shift of the pole brought Europe into sufficiently high latitudes to permit of the formation of an ice sheet, but the large variations of climate during the Ice Age, as shown by the interglacial periods, were due to the oscillations of the solar energy

If two complete cycles of solar radiation occurred during the Pleistocene period, it is possible to account for four advances of the ice in the Alps as demonstrated by Penck and Bruckner but the interglacial periods were not all warm The Gunz Mindel and the Riss Würm interglacial periods occurred at the maximum of the solar radiation and were, therefore, warm interglacial periods, but the Mindel Riss interglacial period occurred at a minimum of solar radiation and was, therefore, a cold interglacial period

At a maximum of solar radiation, that is during a warm interglacial period, the climate of north west Europe was warm and very wet with a relatively small annual variation of temperature As the intensity of solar radiation decreased, the mean temperature fell and the annual variation of temperature increased At the same time the amount of precipitation decreased The fall of temperature occurred sufficiently rapidly compared with the decrease in precipitation to cause the glaciers of the Alps to advance and for an ice sheet to form over Scandinavia As the solar radiation still further decreased the lack of precipitation caused the glaciers of the Alps to retreat At the minimum of solar radiation, there was a cold interglacial period with low mean temperature a large annual variation of temperature and very low precipitation In fact, a truly continental climate

With these changes of climate went a corresponding change in the flora, the sequence being park land, forest, tundra grass with sparse trees, and steppe In this way it has been found possible to determine a sequence of climates and of fauna and flora for the whole Pleistocene period which is supported by the geological and archæological evidence available In particular it is possible to arrange the sequence of human culture, the geological strata of East Anglia, and the history of the ice in the Alps into the scheme of climate change

The two maxima of solar radiation were accompanied by increased precipitation in all parts of the world, so accounting for the two pluvial periods which are known to have occurred during the Pleistocene period

* Summary of an address delivered before the Royal Society of Edinburgh on June 16 by Dr G C Simpson, F R S

The Mechanism of Variation [1]

By Prof Henry H Dixon, F R S

THE fundamental work on the production of variants by means of X rays and the γ radiation of radio active substances, which has been chiefly carried out during the last two or three years in America, is of profound interest to all students of biology By these means H J Muller found it possible to increase 150 times the minute amount of natural variation which is only accessible to estimation by laborious searching through tens of thousands of individuals It was observed that these variations were completely fortuitous, occurring in any characteristic, in any direction, some quite new, some known as occurring under natural conditions, some losses, some gains, but numerically proportional to the duration of radiation, or to the amount of air ionisation produced by the radiation used

Variations produced by this method are transmitted in breeding experiments to the offspring according to the known laws of heredity, so that there is no doubt that they are represented in the germ plasm by factors or genes They have been transmitted unaltered through fifty generations Changes in the chromosomes, corresponding to observed disturbances in linkage, show that the radiation alters the characteristics through alterations in the architecture of the germ-plasm Breeding experiments emphasise the random nature of the changes, since it has been shown that one gene, of two lying side by side in a chromosome, may be changed, while its *vis à vis*, not the thousandth of a millimetre distant, has remained unaltered The same gene in adjacent cells may also escape modification

This random, but minutely selective, action is just what might be expected to result from disturbances in the germ plasm due to the expulsions of electrons by the short waves of X rays, γ rays, and cosmic rays The great preponderance of lethal variations observed over viable and useful ones is only to be expected when we reflect on the necessary bewildering complexity of structure of the genes and the randomness of the dislocations produced by the radiations

Short waved radiation (X , γ , and cosmic radiation) is then a *vera causa* of variation, and just as in the experiments of Muller Stadler, Goodspeed Olson, etc , all manner of variations are produced and even the same variations repeated, so in nature the similar, but less intense, radiation is responsible at relatively long intervals for similar variations

With the aid of this fundamental new knowledge we have a ready explanation of many of the old standing difficulties in the path of the evolutionist The occurrence of similar morphological features in divergent lines of descent has produced much discussion and has been variously explained as due to homoplasy or innate tendencies, etc According to this new departure radiation acting on the germ plasm is responsible The architecture of the germ plasm of the divergent lines of descent is fundamentally similar Radiation causes all manner of fortuitous variations mostly lethal, and a limited number viable Hence in the lapse of time some of those which are viable and possibly advantageous recur in the diverging lines In the same way many atavisms and instances of parallel development may be explained

The possession of common morphological characters by the individuals of certain groups otherwise considered to be genetically far apart, has led to the self contradictory conception of polyphyletic groups and genera Viewed in the light of this new principle, however, such resemblances are due to nothing else but the reappearance of the same variation conditioned by changes in the genes by the short waved radiations of Nature Inasmuch as the majority of these variations are lethal the number of the viable ones are limited and must recur repeatedly as the phylogeny is extended

Again, instances of discontinuous distribution must often find their explanation in this recurrence of the same variation in different localities

In quite a different domain of evolutionary study this principle may be called in to supply an explanation of the relatively high number of endemics which are said to occur on high mountains Naturally, since variation is proportional to radiation, locations on mountain tops being screened from cosmic radiations by a shallower atmosphere should exhibit a greater number of variations than similar areas on the plains

It has often been pointed out that the uselessness of the intermediate stages in the development of a useful organ constitutes a serious difficulty in the theory of evolution based on the natural selection of accumulating minute variations But the conception of variation arising from within due to intra molecular changes in the germ plasm removes this difficulty It is quite conceivable that a gene, if only it retains viability, will be so altered as to condition the production of a useful character or organ without any intermediate steps being necessary

[1] Last spring when the work of Goodspeed and Olson called my attention to the causation of variation by X rays, I suggested (NATURE, June 29, 1929, p 981) that cosmic radiation is a factor in the production of variation by direct action on the germ plasm At the time I did not know that this suggestion had been made and had been experimentally substantiated by the brilliant work of the American investigators whose results are summarised in this communication —H H D

University and Educational Intelligence

BELFAST — Mr J G Semple, lecturer in pure mathematics at the University of Edinburgh, has been appointed professor of mathematics

CAMBRIDGE The following reappointments are notified Mr L E S Eastham Trinity Hall as university lecturer in advanced and economic entomology Dr T M Harris Christ's as demonstrator in botany , Mr H L H H Green Sidney, as demonstrator in anatomy , Dr S M Manton Girton as demonstrator in comparative anatomy

The vice chancellor announces that the Quick professorship of biology will become vacant next November when the period of three years for which Dr Nuttall was last elected will have ended A meeting for the election of a Quick professor will be held on July 16

The vice chancellor also gives notice that the Downing professorship of medicine is vacant by the death of Dr Bradbury

The Woodwardian professorship of geology will become vacant in October by the resignation of Dr Marr

At Trinity Hall, Mr C Forster Cooper having resigned the office of bursar has been elected to a non-stipendiary fellowship and Dr O H Wansborough-Jones has been elected to a research fellowship

LEEDS —The foundation stone of the new library building presented to the University by Lord Brotherton of Wakefield was laid by the donor on June 24 The Duke of Devonshire, Chancellor of the University, presided, and the meeting was addressed by him and by the vice chancellor the librarian and Lord Brotherton The vice chancellor remarked that Through the munificence of the Lord Brotherton of Wakefield this University will in a short time be in the possession of a library building worthy of the highest aspirations of its scholars its scientists, and its students, adequate to meet the requirements of the complete development of the University in the future unsurpassed if not unrivalled by any similar institution in this country ' A striking innovation is the fact that it will be possible to place a quarter of a million volumes on shelves that are open to the access of all readers A generous donor has given to the University a fine collection of Icelandic books which will find their place on the shelves of the new library building Lord Brotherton announced that it is his intention to house his own collection in the new library, to be held by the University in perpetual trust for the nation It is his desire that access to the books shall be accorded to all properly accredited persons With this end in view, Lord Brotherton is taking the necessary steps to endow the collection

LONDON —The following doctorates have been conferred *D Sc in Chemistry*, Mr Harold Burton (Guy's Hospital Medical School) and Mr C W Shoppee, an external student *D Sc in Soil Bacteriology*, Mr H G Thornton (Rothamsted Experimental Station) *D Sc (Engineering)*, Mr C H M Jenkins (Imperial College—Royal School of Mines) and Mr Burrows Moore (King's College) *D Sc in Botany* Mr C R Darlington, an external student

Prof J K Catterson Smith has been appointed as from Aug 1 to the University chair of electrical engineering tenable at King's College Prof Catterson Smith was educated at the City of London School, the South Western Polytechnic, and the University of Birmingham Since 1923 he has been professor and head of the Department of Electrical Engineering at the Indian Institute of Science, Bangalore, of which he has also officiated as director

THE International Committee and the Sub Committees on Intellectual Co operation of the League of Nations will be holding meetings in Geneva during the whole of the month of July The sub committee of experts on the instruction of youth in the aims and objects of the League of Nations meets on July 3 It is due to the past labours of this committee that so much educational work (including direct teaching) for the League is going forward in various countries Two 'common chapters' have been produced by the Secretariat at Geneva These are intended to form the core of national text books on the subject and will "probably assume a different form in various countries" The British volume is to be produced under the auspices of the newly formed British National Committee on Intellectual Co operation, to avoid its being of too official a character After the other sub committees have completed their labours the thirteenth plenary meeting of the International Committee will take place on July 23 Its principal business will be the discussion of the report of the committee of inquiry into the working of intellectual co operation which met at Easter Considerable changes of organisation are foreshadowed, especially in regard to the Paris Institute The number of subjects to be dealt with under the heading of intellectual co operation have been considerably 'rationalised' It is hoped that by a greater concentration of effort, more concrete results will follow

Historic Natural Events

June 30, 1908 The Siberian Meteorite —A great meteorite fell in the upper basin of the Podkamennaia Tugunska River, Siberia, about 60° N, 71° E The place of fall, as described in 1927, had the appearance of a huge crater, several kilometres across, surrounded by an amphitheatre of mountain chains and peaks The area formerly forest, was completely wrecked, lines of stripped tree trunks without branches or bark lay struck to the ground in parallel rows, their tops away from the centre of fall of the meteorite Even where the pines were standing they were usually trunkless and branchless, and showed signs of having been burnt over an area tens of kilometres across More than a thousand reindeer were killed, some disappeared entirely, burnt remains of others were found The burning was not due to ordinary fire but probably to the cloud of incandescent gases which accompanied the meteorite The force of the impact threw the ground into flat folds, but the greatest damage was done by the air wave At a distance of nearly 400 miles the noise and vibration resembled that of a nearby explosion The air wave probably passed completely round the world, it was clearly shown on micro barographs in England, where its cause was at the time unknown, and it aroused great interest It was described as a succession of four undulations, commencing with a range of about five thousandths of an inch lasting about a quarter of an hour, and then violently interrupted by a sudden, though slight, explosive disturbance which set up different and much faster oscillations for a similar interval

June 30, 1908 Brilliant Sky Glows —In central and western Europe and the British Isles, brilliant sky glows were observed on the night of June 30 and on several succeeding nights, especially July 1 The whole northern part of the sky, up to an elevation of about 45°, was suffused with a reddish hue, varying from pink to Indian red, while in the east the sky was a pale green At midnight fairly small print could be read out of doors It remained as light in the south of England as is normal in the north of Scotland at this season There was no flickering or other indication of aurora, and the phenomenon appears to have been an abnormal prolongation of twilight throughout the night, there is little doubt that, as suggested by Mr Spencer Russell, it was caused by the 'cosmic dust' resulting from the fall of the meteorite described above

June 30, 1926 Floods in Yugoslavia —Heavy floods occurred in many parts of Europe towards the end of June and during July, and in Yugoslavia they were very extensive and prolonged On June 30 and July 1 large areas in southern Serbia and Hertzegovina were under water, Nish, Veles, and Pirot being flooded and ripe crops destroyed Parts of Belgrade were inundated by the Danube and Save About a fortnight later further heavy rain and hail occurred, and the Danube and Save again overflowed, while in Rugovo, Montenegro, 40 people were killed by hail Many dams burst their banks and numerous bridges were destroyed Damage to the extent of about £10,000,000 was done

July 2, 1893 Cloudburst in Cheviots —A hill in the Cheviots, known as Bloody Bush Edge, was visited by a waterspout or cloudburst The day was oppressive and about 10 A M heavy clouds gathered These broke about 1 P M and 'the whole hill and parts of the adjoining hills were covered with a sheet of water" (' British Rainfall ") The peat which forms the surface of the hill was ploughed up to a depth of about five feet, and the rocks beneath laid bare over a space of 30 40 acres The River Breamish rose forty feet in sudden flood, swept away its bridges and destroyed long stretches of roadway

July 3, 875 Cloudburst in Saxony —In Saxony occurred a cloud burst of great violence, Ascheubrunn, a place remote from all water, being washed away with all inhabitants and buildings

July 3, 1863 Hailstorm at Clermont-Ferrand —The day was exceedingly hot, and by 3 P M the sky was covered by an enormous nimbus cloud, with flashes of lightning in quick succession About 6 P M a cloud approached rapidly from the west, at a height estimated as 5000 feet It resembled a huge net in form, the portion represented by the netting showed violent agitation and soon after the arrival of the cloud there was a heavy hailstorm lasting about five minutes, the hailstones being as large as nuts During the fall of the hail there was no wind The hail caused considerable damage wherever it fell, and M Lecoq, who saw the storm and described it in the *Comptes rendus*, stated that the damage was limited to small patches, which were surrounded by undamaged zones, forming a network the meshes of which were irregular but roughly 60 100 metres apart The distribution of the hail corresponded with the form of the cloud

July 3, 1892 Floods at Langtoft —A heavy black cloud with three pendants burst over the hills west of Langtoft in Yorkshire, and a great volume of water flowed into the valley, cutting two deep channels in the chalk The village was flooded to a depth of eight feet, and great damage was done On the same day heavy rain fell near Driffield, and this, added to the water from Langtoft, caused further floods

July 5-6, 1911 Low Antarctic Temperature —During Scott's last Antarctic expedition, a party travelling by sledge from Cape Evans to Cape Crozier met with very low temperatures as soon as they reached the Barrier For more than a week the thermometer was below −60° F, on the night of July 4 5 the minimum temperature was −71° F, and on that of July 5 6, −77° F Although the air was comparatively still, little puffs of wind came eddying across the snow plain with blighting effect, and the party felt the cold severely in their canvas tent

Societies and Academies

LONDON

Royal Society, June 19 —**H R Robinson** and **C L Young** New results of the magnetic spectroscopy of X ray electrons New measurements are given of the energies and intensities of the secondary, tertiary, cathode rays ejected by silver K radiations from a number of elements The results are discussed in their relation to current theories of the interaction of X rays and matter and of the X ray term structure

Royal Meteorological Society, June 18 —**C E P Brooks** and **S T A Mirrlees** Irregularities in the Annual Variation of Temperature in London The late Dr A Buchan enumerated six cold and three warm spells which recurred about the same dates in each year in Scotland in the 1860's To find whether these or similar spells occurred also in London, averages of temperature at Kew Observatory were found for each of the periods 1871 to 1900 and 1901 to 1929, and were combined into five day means a "spell" being defined as a period of five days The details of the curves of annual variation obtained in this way were almost completely different in the two periods, and do not give the slightest support to the idea that there is any abiding tendency for any part of the year to be either cold or warm for the season In particular, the famous 'Buchan cold periods' are abnormally warm as often as they are abnormally cold The nearest approach to a regular cool period occurs in summer when the annual rise of temperature ceases towards the end of July and gives place to a period of variable temperature which continues until the autumn fall sets in about the middle of August, but none of these oscillations occurs with sufficient regularity to enable any special dates to be picked out as definite warm or cold periods —**C E P Brooks** The Climate of the first half of the Eighteenth Century There has been no appreciable change of climate since 1750, but there is much evidence that the first half of the eighteenth century was abnormally dry in western Europe Rainfall figures are discussed for 29 places, and the average deficiency of rainfall is calculated as 7 per cent in England, 15 per cent in France, and 9 per cent in Russia and Sweden South westerly winds were less frequent than now and north westerly winds more frequent, the area of low pressure near Iceland was therefore probably less intense than at present The deficiency of rain was greatest in the south of France, while Italy and Tunis were wetter than now, suggesting that the stormy area in the Gulf of Lyons was highly developed The inquiry is extended to other parts of the world, the slow growth of the 'Big trees' shows that rainfall was slight in western U S A, and the Lake of Mexico was at a low level, but the Caspian Sea and the Nile floods were high and there were many floods in China All these facts agree that the general atmospheric circulation, which governs the rainfall of western Europe and California, was weak, the southerly monsoons of Abyssinia and China, which override the general circulation, were abnormally strong and brought heavy rainfall to those countries

PARIS

Academy of Sciences, May 12 —**Ernest Esclangon** The determination of the position and elements of an object (planet or comet) by three observations corresponding to a small arc of the orbit A mathematical discussion of a method which assumes only that the arc described by the object round the sun during the interval of the observations is a small angle, and this without any hypothesis as to the arc described by the earth in the same interval —**Gabriel Bertrand** and **Mlle Y Beauzemont** The variations of the content in zinc of animals with age the influence of a milk diet Earlier work by Bertrand and Vladesco showed that in mammals the proportion of zinc present is at a maximum at birth, gradually diminished during the period of milk feeding the milk being very poor in zinc, and increases again after weaning Several American workers having recently published results which appear to contradict these conclusions, a critical discussion of the American work is given, and fresh experimental evidence produced supporting the authors' original conclusions —**André Blondel** The application of the mutual impedances to the study of the regimes of networks out of equilibrium —**Maurice Lugeon** The origin of granite In opposition to the view that granitic rocks are due to igneous intrusion from below, it is suggested that during folding movements the mechanical energy has been transformed into its heat equivalent, and the formation of granitic rocks is due to this enormous liberation of heat —Charles Maurain was elected a member of the Section of Astronomy in the place of the late H Andoyer —**G Vrançeanu** The groups of applicability of non holonome varieties —**Paul Alexandroff** The theory of dimension —**L Pontrjagin** A fundamental hypothesis of the theory of dimension —**E D Pompéiu** A functional equation which occurs in a problem of average —**J Dieudonné** The circles of multivalence of limited functions —**Georges Valiron** A class of functional equations **L Kantorovitch** and **E Livenson** The projective ensembles of M Lusin —**Henri Poncin** The flow of heavy fluids —**Emile Merlin** A very general case of the motion of a heterogeneous perfect fluid in rotation, presenting striæ in the form of spirals —**Henri Marcelet** The spectrographic analysis of the fluorescences of some vegetable oils observed under the ultra violet rays As ocular comparisons of fluorescent colours are rather uncertain, a spectrographic method has been used Both the emission and absorption spectra were studied and these were found to be quite different Some technical applications are suggested **Swyngedauw** The theory of balanced dynamos utilised for the measurement of the losses in pulley belts —**S Rosenblum** The fine structure of the magnetic spectrum of the α rays The measurements were made with the large electromagnet of the Academy of Sciences (Bellevue) with modified arrangements giving a higher order of accuracy than in the first experiments The velocities are referred to the velocity of the α radiation of thorium C as unity, and have an accuracy of one part in a thousand —**E Carrière** and **Janssens** The determination of fluorine as calcium fluoride Improvements on a method previously described —**Travers** and **Avenet** The estimation of thiocyanates in coke oven effluents —**Lespieau** Phenyltrimethylene This was obtained in an impure state by the action of zinc on the compound CH_2Br CH_2 $CHBr$ C_6H_5 Purification was effected by cautious treatment with a weak solution of potassium permanganate Its physical and chemical properties are compared with those of allylbenzene and propenylbenzene —**A Seyewetz** and **Brissaud** Water of crystallisation in mineral and organic compounds —**R Clogne, Mlle A Courtois,** and **Cazala** The proportion of arsenic in the wells of Choussy de La Bourboule and the fixation of this arsenic in the organism The proportion of arsenic found varied according to the season between 5 8 and 6 5 mgm per litre Tadpoles were readily acclimatised to this water The amount of arsenic absorbed increased the proportion found in the tadpoles by more than 70 per cent —**Paul Becquerel** The latent

life of fern spores in a vacuum at the temperature of liquid helium The spores, previously dried for six months over barium oxide, were cooled for a period of eleven hours to $-270°$ C, in a bath of liquid helium No difference between the spores thus exposed and those kept at the ordinary temperature could be observed, the germinating power and appearance and ... of the prothallus being similar in both cases ...tu and L Maume The comparative chemi... ...tion of vine leaves removed from different ...ights of the branches J Chaussin and E Blan...rd The physico chemical regulation in the internal medium of some agricultural plants —**Robert Lemesle** Observations relating to *Fusarium anthophilum*, a parasite of *Scabiosa succisa* —**Louis Bounoure** The presence of distinct germinal cells in the blastula of the reddish brown frog —**J de Lépiney** The biology of the pilgrim cricket (*Schistocerca gregaria*) —**L Doljanski, J J Trillat, and Lecomte du Noüy** The action of the X rays on cultures of tissues *in vitro* Previous work on the effect of X rays on tissue cultures *in vitro* has tended to prove exceptional resistance of the latter The author considers that these results were due to faulty technique The experiments described show that the lethal dose is reached after five minutes irradiation —**Raoul M May** Water and the phosphorus combinations of the nerve in the course of degenerescence **Edouard Chatton, André Lwoff, and Mme Marguerite Lwoff** *Phoretophyra nebaliæ* and the interpretation of the evolutive cycle of the ciliated Fœttingeridea —**Radu Codreanu** The internal phase of the evolutive cycle of two forms of *Ophryoglena*, endoparasitic Infusoria of the larvæ of ephemera —**G Ramon** The reciprocal relations of the diphtheria antitoxin and the antigen (toxin and anatoxin)

Diary of Societies

FRIDAY, JUNE 27

ROYAL SOCIETY OF MEDICINE (Otology Section) (at Nottingham) at 2 — Papers by Dr M Evans Prof G Guild Dr Dansham, and L Yates Discussion on the Proceedings of the Committee for the Consideration of Hearing Tests

SATURDAY, JUNE 28

ROYAL SOCIETY OF MEDICINE (Orthopædics Section) (at St Vincent's Orthopædic Hospital Eastcote near Pinner) at 3

ROYAL SOCIETY OF MEDICINE (Otology Section) (at Nottingham) (continued)

TUESDAY, JULY 1

ROYAL SOCIETY OF MEDICINE at 4 30 —Annual General Meeting

FRIDAY, JULY 4

GEOLOGISTS ASSOCIATION (at University College), at 7 30 —Dr C T Trechmann The Relation of the Permian and Trias in North East England —J J Hartley The Volcanic and other Igneous Rocks of Great and Little Langdale Westmorland —*Paper to be taken as read* — F Jessop The Agates and Cherts of Derbyshire with a Brief Account of the History of the Lower Carboniferous Limestone of the Peak District.

ASSOCIATION OF ECONOMIC BIOLOGISTS (at National Institute for Research in Dairying, Shinfield, near Reading)

CONGRESS.

JUNE 21 TO 28.

ROYAL SANITARY INSTITUTE (at Margate,

Friday, *June* 27, at 10 A M —Meetings of Sections and Conferences
C —Maternity and Child Welfare (Including School Hygiene)
E —Hygiene in Industry
F —Veterinary Hygiene
II —Representatives of Port Sanitary Authorities
III —National Health Insurance Services.

SUMMER MEETING.

JUNE 30 TO JULY 4

INSTITUTION OF MECHANICAL ENGINEERS (at Bristol).
